&\geq 2\sum_{i\in S\setminus j}\beta_i.
\end{aligned}$$

Similarly to before, if there are C such j in Case II, then the total cost of Case II is at least 0 if $C = 1$, and $2(C-1)$ if $C \geq 2$.

Case III, if $1 - \alpha_j \sum_{i=1}^{d-1}\beta_i > 0$ and $1 - \alpha_j\beta_j < 0$, then it means $1/\beta_j < \alpha_j < \frac{1}{\sum_{i=1}^{d-1}\beta_i}$. The cost of the row is,

$$\begin{aligned}
&= 1 - \alpha_j \sum_{i=1}^{d-1}\beta_i + \alpha_j\beta_j - 1 + |\alpha_j| \sum_{i\neq j}|\beta_j| \\
&= 2|\alpha_j| \sum_{i\in\overline{S}}|\beta_i| \\
&= 2|\alpha_j|(\sum_{i\in S}|\beta_i| - 1) \\
&\geq 2\frac{1}{\beta_j}\sum_{i\in S\setminus j}\beta_i.
\end{aligned}$$

If there are C such j in Case III, then the total cost of Case III is at least 0 if $C = 1$, and $2(C\cdot(C-1))$ if $C \geq 2$.

Case IV, if $1-\alpha_j \sum_{i=1}^{d-1} \beta_i > 0$ and $1-\alpha_j\beta_j > 0$, then it means $\alpha_j \leq \min(1/\beta_j, \frac{1}{\sum_{i=1}^{d-1}\beta_i})$. The cost for the case $\alpha_j < 0$ is larger than the cost for case $\alpha > 0$. Thus we can ignore the case $\alpha_j < 0$. The cost of the row is,

$$\begin{aligned}
&= 1 - \alpha_j \sum_{i=1}^{d-1} \beta_i + 1 - \alpha_j\beta_j + |\alpha_j| \sum_{i \neq j} |\beta_j| \\
&= 2 - 2\alpha_j\beta_j + 2\alpha_j \sum_{i \in \overline{S}} |\beta_i|.
\end{aligned}$$

If $\beta_j < \sum_{i\in\overline{S}} |\beta_i|$, we know that the cost is at least 2. Otherwise, using $\alpha_j \leq 1$, we have the cost is at least $2 - 2\beta_j + \sum_{i\in\overline{S}} |\beta_i|$. Let T denote the set of those j with $\beta_j \geq \sum_{i\in\overline{S}} |\beta_i|$. If $|T| = 1$, we know that cost is at least 0. If $|T| \geq 2$, then the cost is at least

$$\begin{aligned}
&= \sum_{j\in T} (2 - 2\beta_j + 2\sum_{i\in\overline{S}} |\beta_i|) \\
&\geq 2|T| - 2\sum_{j\in S} \beta_j + 2|T| \sum_{i\in\overline{S}} |\beta_i| \\
&\geq 2|T| - 2 + 2(|T|-1) \sum_{i\in\overline{S}} |\beta_i| \\
&\geq 2(C-1).
\end{aligned}$$

Now we discuss the case where $j \in \overline{S}$, which means $\beta_j < 0$.

Case V if $1 - \alpha_j \sum_{i=1}^{d-1} \beta_i < 0$ and $1 - \alpha_j\beta_j < 0$, then it means $\alpha_j > 1/\sum_{i=1}^{d-1} \beta_i$ and $\alpha_j < 1/\beta_j$. Notice that this case will never happen, because $\sum_{i=1}^{d-1} \beta_i = 1$ and $\alpha_j < 0$.

Case VI if $1-\alpha_j \sum_{i=1}^{d-1} \beta_i < 0$ and $1-\alpha_j\beta_j < 0$, then it means $\alpha_j \geq \max(1/\sum_{i=1}^{d-1} \beta_i, 1/\beta_j)$.

Because of $\beta_j < 0$, then $\alpha_j \geq 1$. The cost of that is,

$$
\begin{aligned}
&= \alpha_j \sum_{i=1}^{d-1} \beta_i - 1 + 1 - \alpha_j \beta_j + |\alpha_j| \sum_{i \neq j} |\beta_i| \\
&= 2\alpha_j \sum_{i \in S} |\beta_i| \\
&\geq 2. && \text{by } \alpha_j \geq 1 \text{ and } \sum_{i \in S} |\beta_i| \geq 1.
\end{aligned}
$$

Case VII if $1 - \alpha_j \sum_{i=1}^{d-1} \beta_i > 0$ and $1 - \alpha_j \beta_j < 0$, then it means $\alpha_j < \min(1/\beta_j, 1/\sum_{i=1}^{d-1} \beta_i)$. Because $\beta_j < 0$ and $\sum_{i=1}^{d-1} \beta_i = 1$, thus $\alpha_j < 1/\beta_j$. The cost of that row is,

$$
\begin{aligned}
&= 1 - \alpha_j \sum_{i=1}^{d-1} \beta_i + \alpha_j \beta_j - 1 + |\alpha_j| \sum_{i \neq j} |\beta_i| \\
&= 2|\alpha_j| \sum_{i \in \overline{S} \setminus j} |\beta_i| \\
&\geq 2 \frac{1}{|\beta_j|} \sum_{i \in \overline{S} \setminus j} |\beta_i|.
\end{aligned}
$$

If there are C such j in Case VII, then the total cost of Case VII is at least 0 if $C = 1$, and $2(C \cdot (C-1))$ if $C \geq 2$.

Case VIII if $1 - \alpha_j \sum_{i=1}^{d-1} \beta_i > 0$ and $1 - \alpha_j \beta_j > 0$, then it means $1/\beta_j < \alpha_j < 1/\sum_{i=1}^{d-1} \beta_i$. The cost of that row,

$$
\begin{aligned}
&= 1 - \alpha_j \sum_{i=1}^{d-1} \beta_i + 1 - \alpha_j \beta_j + |\alpha_j| \sum_{i \neq j} |\beta_i| \\
&= 2 - 2\alpha_j \beta_j + 2|\alpha_j| \sum_{i \in \overline{S} \setminus j} |\beta_i|.
\end{aligned}
$$

If $\alpha_j > 0$, then the cost is always at least 2. If $\alpha_j < 0$, the cost is at least,

$$
2 - 2|\alpha_j \beta_j| + 2|\alpha_j| \sum_{i \in \overline{S} \setminus j} |\beta_i|.
$$

If $\sum_{i\in\overline{S}\setminus j}|\beta_i| > |\beta_j|$, we also have cost at least 2. Otherwise, we have

$$2-2|\alpha_j|(|\beta_j|-\sum_{i\in\overline{S}\setminus j}|\beta_i|)=\begin{cases}2-2|\beta_j|+2\sum_{i\in\overline{S}\setminus j}|\beta_i| & \text{if } 1/|\beta_j|\leq 1,\\ 2\frac{1}{|\beta_j|}\sum_{i\in\overline{S}\setminus j}|\beta_i| & \text{if } 1/|\beta_j|>1.\end{cases}$$

Let C denote the number of such j with $1/|\beta_j|\leq 1$. If $C=1$, the cost is at least 0. If $C\geq 2$, the cost is at least $2C$. Let C' denote the number of such j with $1/|\beta_j|>1$. If $C'=1$, the cost is at least 0, if $C'\geq 2$, the cost is at least $2(C'(C'-1))$. Overall, putting all the eight cases together, we complete the proof. □

17.6.3 Hard instance for oblivious subspace embedding and more row subset selection

The goal in this section is to prove Theorem 17.6.28. By applying Yao's minmax principle, it suffices to prove Theorem 17.6.25.

17.6.3.1 Definitions

We first give the definition of total variation distance and Kullback-Leibler divergence.

Definition 17.6.1. [LPW09, Ver14] The total variation distance between two probability measures P and Q on the measurable space $(\mathcal{X}, \mathcal{F})$ is defined as,

$$D_{\mathrm{TV}}(P, Q) = \sup_{\mathcal{A} \in \mathcal{F}} |P(\mathcal{A}) - Q(\mathcal{A})|.$$

The Kullback-Leibler(KL) divergence of P and Q is defined as,

$$D_{\mathrm{KL}}(P||Q) = \mathop{\mathbb{E}}_{P}\left(\log \frac{\mathrm{d}P}{\mathrm{d}Q}\right) = \int_{\mathcal{X}} \left(\log \frac{\mathrm{d}P}{\mathrm{d}Q}\right) \mathrm{d}P.$$

Lemma 17.6.9. *[Pin60, Tsy09, CK11] Pinsker's inequality states that, if P and Q are two probability distributions on a measurable $(\mathcal{X}, \mathcal{F})$, then*

$$D_{\mathrm{TV}}(P, Q) \leq \sqrt{\frac{1}{2} D_{\mathrm{KL}}(P||Q)}.$$

Lemma 17.6.10. *For any Gaussian random variable $x \sim N(0, \sigma^2)$, we have, for any $a > 0$*

$$\Pr[|x| < a] \lesssim \frac{a}{\sigma}.$$

Proof.

$$\begin{aligned}
\Pr[|x| < a] &= \operatorname{erf}(\frac{a}{\sigma\sqrt{2}}) \\
&\leq (1 - e^{-\frac{-4a^2}{2\sigma^2\pi}})^{\frac{1}{2}} && \text{by } 1 - \exp(-4x^2/\pi) \geq \operatorname{erf}(x)^2 \\
&\leq (\frac{4a^2}{2\sigma^2\pi})^{\frac{1}{2}} && \text{by } 1 - e^{-x} \leq x \\
&\lesssim \frac{a}{\sigma}.
\end{aligned}$$

□

Lemma 17.6.11. *Let $V \in \mathbb{R}^{n\times m}$ be a matrix with orthonormal columns. Let $\mathcal{H}'$ be a distribution over $V^\top A$, where $A \in \mathbb{R}^{n\times k}$ is a random matrix with each entry i.i.d. Gaussian $N(0,1)$. Denote $\mathcal{H}$ as a distribution over $H \in \mathbb{R}^{m\times k}$, where each entry of H is drawn from i.i.d. Gaussian $N(0,1)$. Then, $\mathcal{H}$ and $\mathcal{H}'$ are the same distribution.*

Proof. It is clear that each entry of $V^\top A$ is a random Gaussian variable from $N(0,1)$, so our goal is to prove the entries of $V^\top A$ are fully independent. Since the the j^{th} column of $V^\top A$ only depends on A_j, the variables from different columns are fully independent. Now, we look at one column of $x = V^\top A_j$. The density function is

$$f(x) = \frac{1}{\sqrt{(2\pi)^m |V^\top V|}} \exp\left(-\frac{1}{2} x^\top V^\top V x\right) = \frac{1}{\sqrt{(2\pi)^m}} \exp\left(-\frac{1}{2} x^\top x\right),$$

which is exactly the density function of $N(0, I_m)$. Thus $x \in N(0, I_m)$. Therefore, all the entries of $V^\top A$ are fully independent. □

Lemma 17.6.12 (Matrix Determinant Lemma)**.** *Suppose $A \in \mathbb{R}^{n\times n}$ is an invertible matrix, and $u, v \in \mathbb{R}^n$. Then,*

$$|A + uv^\top| = (1 + v^\top A^{-1} u)|A|.$$

Lemma 17.6.13 (KL divergence between two multivariate Gaussians [PP+08][1])**.** *Given two d-dimensional multivariate Gaussian distribution $N(\mu_1, \Sigma_1)$ and $N(\mu_2, \Sigma_2)$, then*

$$D_{\mathrm{KL}}(N(\mu_1||\Sigma_1), N(\mu_2, \Sigma_2)) = \frac{1}{2}\left(\log\frac{|\Sigma_2|}{|\Sigma_1|} - d + \mathrm{tr}(\Sigma_2^{-1}\Sigma_1) + (\mu_2 - \mu_1)^\top \Sigma_2^{-1}(\mu_2 - \mu_1)\right).$$

Lemma 17.6.14 (Sherman-Morrison formula)**.** *Suppose $A \in \mathbb{R}^{n\times n}$ is an invertible matrix and $u, v \in \mathbb{R}^n$. Suppose furthermore that $1 + v^\top A^{-1}u \neq 0$. Then the Sherman-Morrison formula states that*

$$(A + uv^\top)^{-1} = A^{-1} - \frac{A^{-1}uv^\top A^{-1}}{1 + v^\top A^{-1}u}. \tag{17.23}$$

17.6.3.2 Main results

Lemma 17.6.15. *Let $V \in \mathbb{R}^{n\times m}$ be a matrix with orthonormal columns, and let $A \in \mathbb{R}^{n\times k}$ be a random matrix with each entry drawn from i.i.d. Gaussian $N(0, 1)$. We denote the distribution $\mathcal{D}_i$ over $D_i \in \mathbb{R}^{(m+1)\times k}$ where*

$$D_i = \begin{bmatrix} V^\top A \\ A^i \end{bmatrix}.$$

If $\|(V^\top)_i\|_2^2 < \frac{1}{2}$, then

$$D_{\mathrm{TV}}(\mathcal{D}_i, \mathcal{G}) \leq O(k\|V^i\|_2) + 2^{-\Theta(k)},$$

where $\mathcal{G}$ is a distribution over $G \in \mathbb{R}^{(m+1)\times k}$, where each entry of G is drawn from the i.i.d. Gaussian $N(0, 1)$.

[1] http://stats.stackexchange.com/questions/60680/kl-divergence-between-two-multivariate-gaussians

Proof. Let $\mathcal{H}$ be a distribution over $H \in \mathbb{R}^{m\times k}$, where each entry of H is an i.i.d. Gaussian $N(0,1)$. Let $\mathcal{H}'$ be a distribution over $V^\top A$. According to Lemma 17.6.11, $\mathcal{H}$ and $\mathcal{H}'$ are the same distribution.

We define matrix $V^{\neg i} \in \mathbb{R}^{n\times m}$ as

$$V^{\neg i} = \begin{bmatrix} (V^1)^\top & (V^2)^\top & \cdots & (V^{i-1})^\top & 0 & (V^{i+1})^\top & \cdots & (V^n)^\top \end{bmatrix}^\top,$$

where V^i denotes the i^{th} row of $V \in \mathbb{R}^{n\times m}, \forall i \in [n]$.

Let $\mathcal{G}$ be a distribution over $G \in \mathbb{R}^{(m+1)\times k}$, where each entry of G is an i.i.d. Gaussian $N(0,1)$. Let $\mathcal{P}_i$ be a distribution over $P_i \in \mathbb{R}^{(m+1)\times k}$, where

$$P_i = \begin{bmatrix} (V^{\neg i})^\top A \\ A^i \end{bmatrix}.$$

Let $\widehat{\mathcal{P}}_i$ be a distribution over $\widehat{P}_i \in \mathbb{R}^{m\times k}$, where $\widehat{P}_i = (V^{\neg i})^\top A$. Then we have:

$$D_{\mathrm{TV}}(\mathcal{P}_i, \mathcal{G}) = D_{\mathrm{TV}}(\widehat{\mathcal{P}}_i, \mathcal{H}') = D_{\mathrm{TV}}(\widehat{\mathcal{P}}_i, \mathcal{H}). \tag{17.24}$$

The first equality is because $(V^{\neg i})^\top A$ is independent from A^i. The second equality follows the Lemma 17.6.11.

Claim 17.6.16. *If* $\|V^i\|_2^2 \leq \frac{1}{2}$,

$$D_{\mathrm{KL}}(\widehat{\mathcal{P}}_i || \mathcal{H}) = -\frac{k}{2}\left(\log(1 - \|V^i\|_2^2) + \|V^i\|_2^2\right) \leq k\|V^i\|_2^2.$$

Proof. Let $\widehat{P}_i \sim \widehat{\mathcal{P}}_i, H \sim \mathcal{H}$. Notice that different columns of $\widehat{P}_i$ are i.i.d, and all entries of H are fully independent. We can look at one column of $\widehat{P}_i$ and H. Since $\widehat{P}_i = (V^{\neg i})^\top A$, it is easy to see that its column is drawn from $N(0, \Sigma_1)$ where $\Sigma_1 = I_m - (V^i)^\top V^i$. Since H is fully independent, each column of H is drawn from $N(0, \Sigma_2)$ where $\Sigma_2 = I_m$. Let $p(x)$

be the pdf of the column of $\widehat{P}_i$, and let $q(x)$ be the pdf of the column of H. We have the following calculation [PP+08][2],

$$\begin{aligned}
D_{\mathrm{KL}}(\widehat{\mathcal{P}}_i||\mathcal{H}) &= \frac{k}{2}\left(\log\frac{|\Sigma_2|}{|\Sigma_1|} - m + \mathrm{tr}(\Sigma_2^{-1}\Sigma_1)\right) \\
&= \frac{k}{2}\left(\log\frac{|I_m|}{|I_m - (V^i)^\top V^i|} - m + \mathrm{tr}(I_m - (V^i)^\top V^i)\right) \\
&= \frac{k}{2}\left(-\log|I_m - (V^i)^\top V^i| - m + m - \|V^i\|_2^2\right) \\
&= \frac{k}{2}\left(-\log(1 - \|V^i\|_2^2) - m + m - \|V^i\|_2^2\right) \\
&= -\frac{k}{2}\left(\log(1 - \|V^i\|_2^2) + \|V^i\|_2^2\right) \\
&\leq -\frac{k}{2}\cdot 2\|V^i\|_2^2 \\
&= k\|V^i\|_2^2.
\end{aligned}$$

The first equality is due to Lemma 17.6.13. The sixth equality follows by $\Sigma_2 = I_m$ and $\Sigma_1 = I_m - (V^i)^\top V^i$. The eighth equality follows by Lemma 17.6.12. The first inequality follows by $\log(1-x) + x \geq -2x$, when $0 < x < 1/2$.

□

According to Lemma 17.6.9, we have

$$D_{\mathrm{TV}}(\widehat{\mathcal{P}}_i, \mathcal{H}) \leq \sqrt{\frac{1}{2}D_{\mathrm{KL}}(\widehat{\mathcal{P}}_i||\mathcal{H})} \leq \sqrt{k}\|V^i\|_2. \tag{17.25}$$

Now, we want to argue that $D_{\mathrm{TV}}(\mathcal{D}_i, \mathcal{P}_i)$ is small, where $\mathcal{D}_i$ is a distribution over $D_i \in \mathbb{R}^{(m+1)\times k}$ that

$$D_i = \begin{bmatrix} V^\top A \\ A^i \end{bmatrix}.$$

[2] http://stats.stackexchange.com/questions/60680/kl-divergence-between-two-multivariate-gaussians

For a fixed $x \in \mathbb{R}^k$, let $\widehat{\mathcal{D}}_i(x)$ be a distribution over $\widehat{D}_i(x) \in \mathbb{R}^{m \times k}$, where $\widehat{D}_i(x) = (V^{\neg i})^\top A + (V^i)^\top x$. Let $p(x)$ be the pdf of $(A^i)^\top$, then

$$D_{\mathrm{TV}}(\mathcal{D}_i, \mathcal{P}_i) = \int D_{\mathrm{TV}}\left(\widehat{\mathcal{D}}_i(x), \widehat{\mathcal{P}}_i\right) p(x) \mathrm{d}x. \tag{17.26}$$

Now we look at the j^{th} column of $\widehat{D}_i(x)$ and the j^{th} column of $\widehat{P}_i$. The distribution of the previous one is over $N((V^i)^\top x_j, \Sigma_2)$, and the latter distribution as we said before is $N(0, \Sigma_2)$, where $\Sigma_2 = I_m - (V^i)^\top V^i$. Now we can argue that the KL divergence between them is bounded:

$$\begin{aligned}
& D_{\mathrm{KL}}(N((V^i)^\top x_j, \Sigma_2) || N(0, \Sigma_2)) \\
=& \frac{1}{2}\left(\log \frac{|\Sigma_2|}{|\Sigma_2|} - m + \operatorname{tr}(\Sigma_2^{-1}\Sigma_2) + x_j^2 V^i \Sigma_2^{-1} (V^i)^\top\right) \\
=& \frac{1}{2}\left(-m + \operatorname{tr}(I_m) + x_j^2 V^i \Sigma_2^{-1} (V^i)^\top\right) \\
=& \frac{1}{2} x_j^2 V^i \Sigma_2^{-1} (V^i)^\top \\
=& \frac{1}{2} x_j^2 V^i (I_m - (V^i)^\top V^i)^{-1} (V^i)^\top \\
=& \frac{1}{2} x_j^2 V^i \left(I_m + \frac{(V^i)^\top V^i}{1 - V^i (V^i)^\top}\right) (V^i)^\top \\
=& \frac{1}{2} x_j^2 \left(\|V^i\|_2^2 + \frac{\|V^i\|_2^2}{1 - \|V^i\|_2^2}\right) \\
=& \frac{1}{2} x_j^2 \frac{\|V^i\|_2^2}{1 - \|V^i\|_2^2}.
\end{aligned}$$

The first equality is due to Lemma 17.6.13. The fourth equality follows by $\Sigma_2 = I_m - (V^i)^\top V^i$. The fifth equality follows by Lemma 17.6.14.

By summing the KL divergence on all the columns up,

$$D_{\mathrm{KL}}(\widehat{\mathcal{D}}_i(x) || \widehat{\mathcal{P}}_i) = \frac{1}{2}\|x\|_2^2 \frac{\|V^i\|_2^2}{1 - \|V^i\|_2^2}.$$

Applying Lemma 17.6.9 again, we get

$$D_{\mathrm{TV}}(\widehat{\mathcal{D}}_i(x), \widehat{\mathcal{P}}_i) \leq \sqrt{\frac{1}{2} D_{\mathrm{KL}}(\widehat{\mathcal{D}}_i(x) || \widehat{\mathcal{P}}_i)} = \frac{\|x\|_2 \|V^i\|_2}{2\sqrt{1 - \|V^i\|_2^2}}.$$

Plugging it into Equation (17.26), we get

$$\begin{aligned}
D_{\mathrm{TV}}(\mathcal{D}_i, \mathcal{P}_i) &= \int D_{\mathrm{TV}}\left(\widehat{\mathcal{D}}_i(x), \widehat{\mathcal{P}}_i\right) p(x) \mathrm{d}x \\
&= \int_{\|x\|_2 \leq 10k} D_{\mathrm{TV}}\left(\widehat{\mathcal{D}}_i(x), \widehat{\mathcal{P}}_i\right) p(x) \mathrm{d}x + \int_{\|x\|_2 > 10k} D_{\mathrm{TV}}\left(\widehat{\mathcal{D}}_i(x), \widehat{\mathcal{P}}_i\right) p(x) \mathrm{d}x \\
&\leq \int_{\|x\|_2 \leq 10k} D_{\mathrm{TV}}\left(\widehat{\mathcal{D}}_i(x), \widehat{\mathcal{P}}_i\right) p(x) \mathrm{d}x + \int_{\|x\|_2 > 10k} p(x) \mathrm{d}x \\
&\leq \int_{\|x\|_2 \leq 10k} \frac{\|x\|_2 \|V^i\|_2}{2\sqrt{1 - \|V^i\|_2^2}} p(x) \mathrm{d}x + \int_{\|x\|_2 > 10k} p(x) \mathrm{d}x \\
&\leq \frac{10k\|V^i\|_2}{2\sqrt{1 - \|V^i\|_2^2}} + \int_{\|x\|_2 > 10k} p(x) \mathrm{d}x \\
&\leq \frac{10k\|V^i\|_2}{2\sqrt{1 - \|V^i\|_2^2}} + 2^{-\Theta(k)}.
\end{aligned}$$

The first inequality just follows from the fact that total variation distance is smaller than 1. The second inequality is what we plugged in. The last inequality follows from the fact that $x \sim N(0, I_k)$ and from the tail bounds of a Gaussian.

Together with Equation (17.24) and Equation (17.25), we can get

$$\begin{aligned}
D_{\mathrm{TV}}(\mathcal{D}_i, \mathcal{G}) &\leq D_{\mathrm{TV}}(\mathcal{D}_i, \mathcal{P}_i) + D_{\mathrm{TV}}(\mathcal{G}, \mathcal{P}_i) \\
&= D_{\mathrm{TV}}(\mathcal{D}_i, \mathcal{P}_i) + D_{\mathrm{TV}}(\widehat{\mathcal{P}}_i, \mathcal{H}) \\
&\leq \frac{10k\|V^i\|_2}{2\sqrt{1 - \|V^i\|_2^2}} + 2^{-\Theta(k)} + \sqrt{k}\|V^i\|_2 \\
&\leq 10k\|V^i\|_2 + 2^{-\Theta(k)} + \sqrt{k}\|V^i\|_2.
\end{aligned}$$

The last inequality follows by $\|V^i\|_2^2 \leq \frac{1}{2}$. Then, we have completed the proof.

□

Lemma 17.6.17. *$A \in \mathbb{R}^{r \times k}$ $(r \geq k)$ is a random matrix for which each entry is i.i.d. $N(0,1)$. With probability at least $1 - e^{-\Theta(r)}$, the maximum singular value $\|A\|_2$ is at most $O(\sqrt{r})$.*

Proof. Since $A \in \mathbb{R}^{k \times r}$ is a random matrix with each entry i.i.d. $N(0,1)$, this follows by standard arguments (Proposition 2.4 in [RV10]). Since $r \geq k$, with probability at least $1 - e^{-\Theta(r)}$, $\|A\|_2$ is at most $O(\sqrt{r})$. □

Definition 17.6.2. Let $V \in \mathbb{R}^{n \times r}$ be a matrix with orthonormal columns, and let each entry of $A \in \mathbb{R}^{k \times r}$ be a random variable drawn from an i.i.d. Gaussian $N(0,1)$. Define event $\widehat{\mathcal{E}}(A, V, \beta, \gamma)$ to be: $\forall y \in \mathbb{R}^n$, $\|y\|_1 \leq O(k^\gamma)$ and each coordinate of y has absolute value at most $1/k^\beta$, and also $AV^\top y$ has at most $O(k/\log k)$ coordinates with absolute value at least $\Omega(1/\log k)$, and $\|A\|_2 \leq O(\sqrt{r})$.

Lemma 17.6.18. *For any $k \geq 1$, and any constants $c_2 \geq c_1 \geq 1$, let $k \leq r = O(k^{c_1}), r \leq n = O(k^{c_2})$, let $V \in \mathbb{R}^{n \times r}$ be a matrix with orthonormal columns, and let each entry of $A \in \mathbb{R}^{k \times r}$ be a random variable drawn from i.i.d. Gaussian $N(0,1)$. Furthermore, if β and γ are two constants which satisfy $\beta > \gamma > 0$ and $\beta + \gamma < 1$,*

$$\Pr\left[\widehat{\mathcal{E}}(A, V, \beta, \gamma)\right] \geq 1 - 2^{-\Theta(k)}.$$

Proof. Due to Lemma 17.6.17, with probability at least $1 - 2^{-\Theta(r)}$, $\|A\|_2 \leq O(\sqrt{r})$, so we can restrict attention to $\|A\|_2 \leq O(\sqrt{r})$ in the following proof.

Take any $y \in \mathbb{R}^n$ which has each non-zero coordinate with absolute value at most $1/k^\beta$, and write it as $y = \sum_{j=j_0}^{+\infty} y^j$, where the coordinates in y^j have absolute value in the

range $[2^{-j-1}, 2^{-j})$, and the supports of different y^j are disjoint. Since each coordinate of y is at most $1/k^\beta$, $2^{-j_0} = 1/k^\beta$. Since $\|y\|_1 \leq O(k^\gamma)$, the support size of $y^j \in \mathbb{R}^n$ is at most $s_j \leq O(2^{j+1}k^\gamma)$, so it follows that

$$\|y^j\|_2 \leq \sqrt{s_j \cdot 2^{-2j}} \leq \sqrt{2^{-j+1}k^\gamma}.$$

We also know $\|y^j\|_2 \geq \sqrt{s_j \cdot 2^{-2j-2}}$. Then we can conclude that y^j has 2-norm $\Theta(2^{-j}\sqrt{s_j})$. Now we state an ϵ-net for all the possible y^j: let $\epsilon = O(1/(nrk^3)) = O(1/(k^{c_1+c_2+3}))$. Let $\mathcal{N}_j \subset \mathbb{R}^n$ be the following:

$$\mathcal{N}_j = \left\{p \in \mathbb{R}^n \mid \exists q \in \mathbb{Z}^n, \text{ s.t. } p = \epsilon q, \|p\|_1 \leq O(k^\gamma), \forall i \in [n], \text{ either } |p_i| \in [2^{-j-1}, 2^{-j}) \text{ or } p_i = 0\right\}.$$

Obviously, for any y^j, there exists $p \in \mathcal{N}_j$ such that $\|y^j - p\|_\infty \leq \epsilon = O(1/(k^{c_1+c_2+3}))$, since $n \leq O(k^{c_2})$, $\|y^j - p\|_2 \leq \|y^j - p\|_1 \leq n\|y^j - p\|_\infty \leq O(1/k^{c_1+3})$. Now let us consider the size of $\mathcal{N}_j$. If $p \in \mathcal{N}_j$, the choice of one coordinate of p is at most $2/\epsilon+1$. And since $\|p\|_1 \leq O(k^\gamma)$ and each coordinate of p has absolute value at least 2^{-j-1}, the number of supports of p is at most $O(2^{j+1}k^\gamma)$. Therefore,

$$\begin{aligned}
|\mathcal{N}_j| &\leq (n+1)^{O(2^{j+1}k^\gamma)} \cdot (2/\epsilon+1)^{O(2^{j+1}k^\gamma)} \\
&\leq 2^{O(2^{j+1}k^\gamma(\log n + \log(2/\epsilon+1))} \\
&\leq 2^{O(2^{j+1}k^\gamma \log k)}.
\end{aligned}$$

The last inequality follows from $n \leq O(k^{c_2}), r \leq O(k^{c_1}), \epsilon = O(1/(rnk^3))$.

We define an event $\mathcal{E}(y^j)$ to be: $AV^\top y^j$ has $k/\log^2 k$ coordinates which are each at least $2/\log^2 k$ in absolute value. Now, we want to show,

Claim 17.6.19. *For any $j \geq j_0$, for a fixed $y^j \in \mathbb{R}^n$,*

$$\Pr\left[\mathcal{E}(y^j) \text{ happens }\right] \leq 2^k e^{-\Theta(k/(\|y^j\|_2^2 \log^6 k))} \leq e^{-\Theta(2^{j-1}k^{1-\gamma}/\log^6 k)}.$$

Proof. We let p be the probability that the absolute value of a single coordinate of $AV^\top y^j$ is at least $1/\log^2 k$. Notice that each coordinate of $AV^\top y^j$ is i.i.d. Gaussian $N(0, \|V^\top y^j\|_2^2)$ and because for any Gaussian random variable g, $\Pr[|g| \geq t] \leq \exp(-\Theta(t^2/\sigma^2))$, then $p \leq \exp(-1/(\|V^\top y^j\|_2^2 \log^4 k))$, by plugging $\sigma^2 = \|V^\top y^j\|_2^2$ and $t = 1/\log^2 k$. So the probability $AV^\top y^j$ has $k/\log^2 k$ coordinates which are each at least $1/\log^2 k$ in absolute value is,

$$\begin{aligned}
\sum_{i=k/\log^2 k}^{k} p^i (1-p)^{k-i} \binom{k}{i} \leq & \sum_{i=k/\log^2 k}^{k} p^i \binom{k}{k/2} \leq 2p^{k/\log^2 k} 2^k \\
\leq & \; e^{-\Theta(kt^2/(\sigma^2 \log^2 k))} 2^k \\
\leq & \; e^{-\Theta(k/(\|V^\top y^j\|_2^2 \log^6 k))} 2^k \\
\leq & \; e^{-\Theta(k/(\|y^j\|_2^2 \log^6 k))} 2^k \\
\leq & \; e^{-\Theta(k/(2^{-2j} s_j \log^6 k))} 2^k \\
\leq & \; e^{-\Theta(k/(2^{-j+1} k^\gamma \log^6 k))} 2^k \\
= & \; e^{-\Theta(k/(2^{-j+1} k^\gamma \log^6 k))} \\
\leq & \; e^{-\Theta(2^{j-1} k^{1-\gamma}/\log^6 k)},
\end{aligned}$$

where the second step follows from $p \leq \exp(-\Theta(t^2/\sigma^2))$, the forth step follows from $\|V^\top y^j\|_2^2 \leq \|V\|_2^2 \|y^j\|_2^2 \leq \|y^j\|_2^2$, the fifth step follows from $\|y^j\|_2^2 \leq 2^{-2j} s_j$, the sixth step follows from $s_j \leq O(2^{j+1} k^\gamma)$, the seventh step follows from $2^{-j+1} k^\gamma \log^6 k \leq 2^{-j_0+1} k^\gamma \log^6 k \leq 2k^{\gamma-\beta} \log^6 k = o(1)$. □

For $j_1 = \lceil 100(c_1+c_2+1)\log k \rceil = \Theta(\log k)$, consider $j \in [j_1, \infty)$. We have $\| \sum_{j=j_1}^{\infty} y^j \|_2$ is at most $\Theta(2^{-j_1}\sqrt{n}) \leq 1/k^{100(1+c_1)}$, and so

$$\begin{aligned}
\|AV^\top \sum_{j=j_1}^{\infty} y^j\|_1 &\leq \sqrt{k}\|AV^\top \sum_{j=j_1}^{\infty} y^j\|_2 \\
&\leq \sqrt{k}\|A\|_2\|V\|_2\| \sum_{j=j_1}^{\infty} y^j\|_2 \\
&\leq \sqrt{k} \cdot \sqrt{r} \cdot 1/k^{100(1+c_1)} \leq 1/k^{50}.
\end{aligned}$$

The last inequality follows from $r = O(k^{c_1})$. So the contribution of y^j to $\|AV^\top y^j\|_1$ for all $j \geq j_1$ is at most $1/k^{50}$. Thus, if we only consider those j which contribute, i.e., $j_0 \leq j \leq j_1$, we have $O(\log k)$ values of j. Then we can only construct $O(\log k)$ nets $\mathcal{N}_{j_0}, \mathcal{N}_{j_0+1}, \cdots, \mathcal{N}_{j_1}$. Since the size of net $\mathcal{N}_j$ is $2^{\Theta(2^{j+1}k^\gamma \log k)}$, by combining Claim 17.6.19 and taking a union bound, we have

$$\begin{aligned}
\Pr\left[\exists y^j \in \bigcup_{j=j_0}^{j_1} \mathcal{N}_j,\ \mathcal{E}(y^j) \text{ happens}\right] &\leq \sum_{j=j_0}^{j_1} 2^{\Theta(2^{j+1}k^\gamma \log k)} \cdot e^{-\Theta(2^{j-1}k^{1-\gamma}/\log^6 k)} \\
&\leq e^{-\Theta(2^{j_0-1}k^{1-\gamma}/\log^6 k)} \\
&\leq e^{-\Theta(k^{1+\beta-\gamma}/\log^6 k)} \\
&\leq 2^{-\Theta(k)}.
\end{aligned}$$

The second inequality follows since $k^\gamma = o(k^{1-\gamma})$. The third inequality follows since $2^{j_0} \geq k^\beta$. The fourth inequality follows since $1 + \beta - \gamma > 1$.

Then, $\forall j_0 \leq j \leq j_1, \forall \widetilde{y}^j \notin \mathcal{N}_j$, there exists a vector $\widehat{y}^j$ in $\mathcal{N}_j$, such that $\|\widehat{y}^j - \widetilde{y}^j\|_2 \leq$

$1/k^{3+c_1}$. We can upper bound the ℓ_∞ norm of $AV^\top \widehat{y}^j - AV^\top \widetilde{y}^j$ in the following sense,

$$\begin{aligned}
\|AV^\top \widehat{y}^j - AV^\top \widetilde{y}^j\|_\infty &\leq \|AV^\top \widehat{y}^j - AV^\top \widetilde{y}^j\|_2 && \text{by } \|\cdot\|_\infty \leq \|\cdot\|_2 \\
&\leq \|A\|_2 \cdot \|\widehat{y}^j - \widetilde{y}^j\|_2 \\
&\leq \sqrt{r}/k^{3+c_1} && \text{by Claim 17.6.17 and } \|\widehat{y}^j - \widetilde{y}^j\|_2 \leq 1/k^{3+c_1} \\
&= 1/k^2. && \text{by } r \leq O(k^{c_1})
\end{aligned}$$

We let $Y = \{y \in \mathbb{R}^n \mid \|y\|_1 \leq O(k^\gamma) \text{ and each coordinate of } y \leq 1/k^\beta\}$. Since $1/k^2 < 1/\log^2 k$ we can conclude that,

$$\Pr\left[\exists y \in Y, j \geq j_0, \mathcal{E}(y^j) \text{ happens }\right] \leq 2^{-\Theta(k)}. \tag{17.27}$$

Recalling $y = \sum_j y^j$, by Equation (17.27), for any y, with probability at most $2^{-\Theta(k)}$, there are at most $O(\log k) \cdot k/\log^2 k \leq O(k/\log k)$ coordinates for which $AV^\top \sum_{j=j_0}^{j_1} y^j$ (the same statement also holds for $AV^\top \sum_{j=j_0}^{\infty} y^j = AV^\top y$ since we argued that there is negligible "contribution" for those $j > j_1$) is at least $O(\log k)/\log^2 k = O(1/\log k)$ on that coordinate. Summarizing,

$$\Pr\left[\widehat{\mathcal{E}}(A, V, \beta, \gamma)\right] \geq 1 - 2^{-\Theta(k)}.$$

□

Lemma 17.6.20. *For any $t, k \geq 1$, and any constants $c_2 \geq c_1 \geq 1$, let $k \leq r = O(k^{c_1}), r \leq n = O(k^{c_2})$, let $V \in \mathbb{R}^{n\times r}$ be a matrix with orthonormal columns, and let each entry of $A \in \mathbb{R}^{k\times r}, v_1, v_2, \cdots, v_t \in \mathbb{R}^k$ be an i.i.d. Gaussian $N(0,1)$ random variable. For a constant $\alpha \in (0, 0.5)$ which can be arbitrarily small, if $\widehat{\mathcal{E}}(A, V, 0.5 + \alpha/2, 0.5 - \alpha)$ happens, then with probability at least $1 - 2^{-\Theta(tk)}$, there are at least $\lceil t/10 \rceil$ such $j \in [t]$ that $\forall x \in \mathbb{R}^r$ either $\|Ax - v_j\|_1 \geq \Omega(k^{0.5-\alpha})$ or $\|Vx\|_1 \geq \Omega(k^{0.5-\alpha})$ holds.*

Proof. For convenience, we define $\gamma = 0.5 - \alpha$ which can be an arbitrary constant in $(0, 0.5)$. We let constant $\beta = 0.5 + \alpha/2$. Then we have $\beta + \gamma < 1$ and $\beta > \gamma$. Let $v \in \mathbb{R}^k$ be a random vector with each entry drawn from i.i.d. Gaussian $N(0, 1)$. Suppose $\widehat{\mathcal{E}}(A, V, \beta, \gamma)$ happens.

For any $x \in \mathbb{R}^r$, we can find a $y \in \mathbb{R}^n$ such that $y = Vx$. Since $V \in \mathbb{R}^{n\times r}$ has orthonormal columns, $x = V^\top Vx = V^\top y$. Then our goal is to argue that with high probability if $\|AV^\top y - v\|_1 \le O(k^\gamma)$, then $\|y\|_1 > \Omega(k^\gamma)$. Take any $y \in \mathbb{R}^n$ which can be expressed as Vx, and decompose it as $y = y_0 + y_1$, where $y_0 \in \mathbb{R}^n$ and $y_1 \in \mathbb{R}^n$ have disjoint supports, y_0 has each coordinate with absolute value greater than $1/k^\beta$, and y_1 has each coordinate with absolute value at most $1/k^\beta$.

Now we create an ϵ-net for y_0: let $\epsilon = O(1/(rnk^3)) = O(1/k^{c_1+c_2+3})$, we denote $\mathcal{N} \subset \mathbb{R}^n$ as follows:

$$\mathcal{N} = \left\{ p \in \mathbb{R}^n \mid \exists q \in \mathbb{Z}^n, \text{ s.t. } p = \epsilon q, \|p\|_1 \le O(k^\gamma), \forall i \in [n], \text{ either } |p_i| > 1/k^\beta \text{ or } p_i = 0 \right\}.$$

Obviously, for any y_0, there exists $p \in \mathcal{N}$ such that $\|y_0 - p\|_\infty \le \epsilon = O(1/(k^{c_1+c_2+3}))$, since $n \le O(k^{c_2})$, $\|y_0 - p\|_2 \le \|y_0 - p\|_1 \le n\|y_0 - p\|_\infty \le O(1/k^{c_1+3})$. Now let us consider the size of $\mathcal{N}$. If $p \in \mathcal{N}$, the number of choices of one coordinate of p is at most $O(k^\gamma/\epsilon)$. And since $\|p\|_1 \le O(k^\gamma)$ and each coordinate of p has absolute value at least $1/k^\beta$, the number of supports of p is at most $O(k^{\gamma+\beta})$. Therefore,

$$\begin{aligned} |\mathcal{N}| &\le (n+1)^{O(k^{\gamma+\beta})} \cdot O(k^\gamma/\epsilon)^{O(k^{\gamma+\beta})} \\ &\le 2^{O(k^{\gamma+\beta}\log k)}. \end{aligned}$$

The last inequality follows from $n \le O(k^{c_2}), r \le O(k^{c_1}), \epsilon = O(1/(rnk^3))$.

For $y_0 \in \mathbb{R}^n$, we define event $\mathcal{E}_1(y_0)$ as: $\exists$ valid $y_1 \in \mathbb{R}^n$, $\|AV^\top y - v\|_1 \le O(k^\gamma)$, where $y = y_0 + y_1$ is the decomposition of a possible $y \in \mathbb{R}^n$. Here y_1 is valid means that there

exists $y \in \mathbb{R}^n$ such that $\|y\|_1 \leq O(k^\gamma)$ and the decomposition of y is $y = y_0 + y_1$. We define event $\mathcal{E}_2(y_0)$ as: $\exists$ valid y_1, the absolute value of $AV^\top y - v$ is at most $O(1/k^\gamma)$ for at least $k - O(k^{2\gamma})$ coordinates i in $[k]$. We define event $\mathcal{E}_3(y_0)$ as: at least $k - O(k^{2\gamma}) - O(k/\log k)$ coordinates of $Ay_0 - v$ have absolute value at most $O(1/\log k)$.

Claim 17.6.21. *For $y_0 \in \mathbb{R}^n$,*

$$\Pr[\mathcal{E}_3(y_0) \text{ happens }] \geq \Pr[\mathcal{E}_2(y_0) \text{ happens }] \geq \Pr[\mathcal{E}_1(y_0) \text{ happens }].$$

Proof. If $\mathcal{E}_1(y_0)$ happens, then there exists a valid $y_1 \in \mathbb{R}^n$ such that $y = y_0 + y_1$ and $\|AV^\top y - v\|_1 \leq O(k^\gamma)$. For this y, there are at least $k - O(1/k^{2\gamma})$ coordinates of $AV^\top y - v$ with absolute value at most $O(1/k^\gamma)$. Otherwise, $\|AV^\top y - v\|_1 > \Omega(k^\gamma)$. Thus, $\mathcal{E}_1(y_0)$ implies $\mathcal{E}_2(y_0)$.

Now we want to show $\mathcal{E}_2(y_0)$ implies $\mathcal{E}_3(y_0)$. We suppose $\mathcal{E}_2(y_0)$ happens. Then there is a valid y_1 such that there are at least $k - O(1/k^{2\gamma})$ coordinates of $AV^\top y - v$ with absolute value at most $O(1/k^\gamma)$, where $y = y_0 + y_1$. Recall that the event $\widehat{\mathcal{E}}(A, V, \beta, \gamma)$ happens, for any valid y_1 there are at most $O(k/\log k)$ coordinates of $AV^\top y_1$ are at least $\Omega(1/\log k)$. Therefore,

$$AV^\top y_0 - v = \underbrace{AV^\top y - v}_{\substack{\geq k - O(k^{2\gamma}) \text{ coordinates} \\ \text{each } \leq O(1/k^\gamma)}} - \underbrace{AV^\top y_1}_{\substack{\leq O(k/\log k) \text{ coordinates} \\ \text{each} \geq \Omega(1/\log k)}}.$$

Therefore, at least $k - O(k^{2\gamma}) - O(k/\log k)$ coordinates of $Ay_0 - v$ in absolute value is at most $O(1/\log k) + O(1/k^\gamma) = O(1/\log k)$ □

Claim 17.6.22. *Define event $\mathcal{F}_1$ to be the situation for which there exists $1/2$ of the coordinates of $v \in \mathbb{R}^k$ that are at least $1/100$. The probability this event $\mathcal{F}_1$ holds is at least $1 - 2^{-\Theta(k)}$.*

Proof. Note that $\overline{\mathcal{F}}_1$ means there exist $k/2$ of the coordinates of $v \in \mathbb{R}^k$ which are at most $1/100$. Using Lemma 17.6.10, for each single coordinate the probability it is smaller than $1/100$ is $1/200$. Then the probability more than half the coordinates are no more than $1/100$ is

$$\sum_{i=k/2}^{k} p^i (1-p)^{k-i} \binom{k}{i} \leq \sum_{i=k/2}^{k} p^i \binom{k}{k/2} \leq 2p^{k/2} 2^k \leq (1/200)^{\Theta(k)} = 2^{-\Theta(k)}.$$

□

Conditioned on $\mathcal{F}_1$ happening, if $\mathcal{E}_3(y_0)$ happens, then due to the pigeonhole principle, there are at least $\frac{k}{2} - O(k^{2\gamma}) - O(k/\log k)$ coordinates of $AV^\top y_0 - v$ that are at most $O(1/\log k)$ and the corresponding coordinate of v is larger than $1/100$. Now, let us look at the probability on a single coordinate of $AV^\top y_0 - v$.

Claim 17.6.23. *If the i^{th} coordinate of $v \in \mathbb{R}^k$ is at least $1/100$. Then $\Pr[|(AV^\top y_0)_i - (v)_i| \leq O(1/\log k)] \leq O(1/\log k)$.*

Proof. Since $|(v)_i| > 1/100$ and v is independent from $A \in \mathbb{R}^{k \times r}$, for $0 < \eta < 1/100$, $\Pr[|(AV^\top y_0)_i - (v)_i| \leq \eta]$ is always upper bounded by $\Pr[(Ax_0)_i \in [1/100 - \eta, 1/100 + \eta]$. Thus, it suffices to prove an upper bound for $\Pr[(AV^\top x_0)_i \in [1/100 - \eta, 1/100 + \eta]$. Let $f(x)$

be the pdf of $N(0, \sigma^2)$, where $\sigma^2 = \|V^\top y_0\|_2^2, V \in \mathbb{R}^{n \times r}, y_0 \in \mathbb{R}^n$. Then

$$\begin{aligned} & \Pr[(AV^\top y_0)_i \in [1/100 - \eta, 1/100 + \eta]] \\ = & \int_{1/100-\eta}^{1/100+\eta} f(x) \mathrm{d}x \\ \leq & f(1/200) \int_{1/100-\eta}^{1/100+\eta} \mathrm{d}x \\ \leq & O(\eta). \end{aligned}$$

where the last step follows since $f(1/200) \leq 200$. We set $\eta = O(1/\log k)$, then we get the statement. □

Claim 17.6.24. *Conditioned on $\mathcal{F}_1$, for a fixed $y_0 \in \mathbb{R}^n$, with probability at most $2^{-\Theta(k)}$, there are at least $\frac{k}{10}$ coordinates of $AV^\top y_0 - v \in \mathbb{R}^k$ which are at most $O(1/\log k)$ and the corresponding coordinate of v is larger than $1/100$.*

Proof. We look at the coordinate $i \in [k]$ which has $|(v)_i| > 1/100$. The probability $\|(AV^\top y_0)_i - (v)_i\| \leq O(1/\log k)$ is at most $O(1/\log k)$. Due to the independence between different coordinates of v, since there are at least $k/2$ coordinates of v satisfying that they have absolute value greater than $1/100$, with probability at most $2^{-\Theta(k)}$, there are at least $\frac{1}{5} \cdot \frac{k}{2} = k/10$ coordinates of $AV^\top y_0 - v$ which are at most $O(1/\log k)$.

□

Because $\mathcal{E}_3(y_0)$ implies the event described in the above claim when conditioning on $\mathcal{F}_1$, for a fixed y_0, the probability that $\mathcal{E}_3(y_0)$ holds is at most $2^{-\Theta(k)}$. Since $\gamma + \beta < 1$, the $|\mathcal{N}| \leq 2^{k^{o(1)}}$, we can take a union bound over the $\mathcal{N}$:

$$\Pr[\exists y_0 \in \mathcal{N}, \mathcal{E}_1(y_0) \text{ happens }] \leq 2^{-\Theta(k)}.$$

It means that with probability at least $1 - 2^{-\Theta(k)}$, for any $y = y_0 + y_1$ with $y_0 \in \mathcal{N}$, $\|AV^\top y - v\|_1 > \Omega(k^\gamma)$. Let $\widetilde{y} = \widetilde{y}_0 + \sum \widetilde{y}^j$, where $\widetilde{y}_0 \notin \mathcal{N}$. We can find $\widehat{y}_0 \in \mathcal{N}$ which is the closest to $\widetilde{y}_0$. Denote $\widehat{y} = \widehat{y} + \sum \widetilde{y}^j$. Then,

$$\begin{aligned}
\|AV^\top \widehat{y} - v\|_1 &\leq \|AV^\top \widetilde{y} - v\|_1 + \|AV^\top \widetilde{y} - AV^\top \widehat{y}\|_1 && \text{by triangle inequality} \\
&\leq \|AV^\top \widetilde{y} - v\|_1 + \sqrt{k}\|AV^\top \widetilde{y} - AV^\top \widehat{y}\|_2 && \text{by } \|\cdot\|_1 \leq \sqrt{\dim}\|\cdot\|_2 \\
&\leq \|AV^\top \widetilde{y} - v\|_1 + \sqrt{k}\|A\|_2\|\widetilde{y} - \widehat{y}\|_2 \\
&\leq \|AV^\top \widetilde{y} - v\|_1 + \sqrt{k}\cdot\sqrt{r}\cdot\|\widetilde{y}_0 - \widehat{y}_0\|_2 && \text{by } \|A\|_2 \leq \sqrt{r} \\
&\leq \|AV^\top \widetilde{y} - v\|_1 + \sqrt{k}\cdot\sqrt{r}\cdot\epsilon && \text{by } \|\widetilde{y}_0 - \widehat{y}_0\|_2 \leq \epsilon \\
&= \|AV^\top \widetilde{y} - v\|_1 + \sqrt{k}\cdot\sqrt{r}\cdot 1/k^{c_1+3} && \text{by } \epsilon' = 1/k^{c_1+3} \\
&= \|AV^\top \widetilde{y} - v\|_1 + 1/k. && \text{by } r = O(k^{c_1})
\end{aligned}$$

and so if $\|AV^\top \widetilde{y} - v\|_1$ is at most $O(k^\gamma)$ then $\|A\widehat{y} - v\|_1$ is at most $O(k^\gamma)$.

For $j \in [t]$, we now use notation $\mathcal{E}_4(v_j)$ to denote the event: $\exists y_0 \in \mathbb{R}^n$ with $\|y_0\|_1 \leq O(k^\gamma)$ and each non-zero coordinate of y_0 is greater than $1/k^\beta$, at least $k - O(k^{2\gamma}) - O(k/\log k)$ coordinates of $AV^\top y_0 - v_j$ in absolute value are at most $O(1/\log k)$. Based on the previous argument, conditioned on $\widehat{\mathcal{E}}(A, V, \beta, \gamma)$,

$$\Pr[\mathcal{E}_4(v_j)] \leq 2^{-\Theta(k)}.$$

Also notice that, conditioned on $\widehat{\mathcal{E}}(A, V, \beta, \gamma)$, $\forall j \in [t]$, $\mathcal{E}_4(v_j)$ are independent. Thus, conditioned on $\widehat{\mathcal{E}}(A, V, \beta, \gamma)$, due to the Chernoff bound, the probability that there are $\lceil t/10 \rceil$ such j that $\mathcal{E}_4(v_j)$ happens is at most $2^{-\Theta(kt)}$. We define $\mathcal{E}_5(v_j)$ to be the event: $\exists y \in \mathbb{R}^n, \|AV^\top y - v_j\| \leq O(k^\gamma)$ with $\|y\|_1 \leq O(k^\gamma)$. Similar to the proof of Claim 17.6.21, conditioned on $\widehat{\mathcal{E}}(A, V, \beta, \gamma)$, $\mathcal{E}_5(v_j)$ implies $\mathcal{E}_4(v_j)$. Thus, conditioned on $\widehat{\mathcal{E}}(A, V, \beta, \gamma)$, the

probability that there are $\lceil t/10 \rceil$ such j that $\mathcal{E}_5(v_j)$ happens is at most $2^{-\Theta(tk)}$. Then, we complete the proof.

□

Theorem 17.6.25. *For any $k \geq 1$, and any constants c_1, c_2 which satisfy $c_2 - 2 > c_1 > 1$, let $r = \Theta(k^{c_1}), n = \Theta(k^{c_2})$, and let $\mathcal{A}(k, n)$ denote a distribution over $n \times (k + n)$ matrices where each entry of the first $n \times k$ matrix is i.i.d. Gaussian $N(0, 1)$ and the next $n \times n$ matrix is an identity matrix. For any fixed $r \times n$ matrix S and a random matrix $\widehat{A} \sim \mathcal{A}(k, n)$, with probability at least $1 - O(k^{1+\frac{c_1-c_2}{2}}) - 2^{-\Theta(k)}$, there is no algorithm that is able to output a matrix $B \in \mathbb{R}^{n \times r}$ such that*

$$\|BS\widehat{A} - \widehat{A}\|_1 \leq O(k^{0.5-\epsilon}) \min_{\text{rank}-k \ A'} \|A' - \widehat{A}\|_1,$$

where $\epsilon > 0$ is a constant which can be arbitrarily small.

Proof. For convenience, we let $\gamma = 0.5 - \epsilon$ be a constant which can be arbitrarily close to 0.5. Since the last n columns of $\widehat{A}$ is an identity matrix, we can fit the first k columns of $\widehat{A}$, so we have

$$\min_{\text{rank}-k \ A'} \|A' - \widehat{A}\|_1 \leq n.$$

Now, we want to argue that, for a fixed S, with high probability, for any rank-k $n \times r$ matrix B, the cost

$$\|BS\widehat{A} - \widehat{A}\|_1 \geq \Omega(n \cdot k^{\gamma}).$$

Thus, the approximation gap will be at least $\Omega(k^{\gamma})$.

We denote the SVD of $S = U_S \Sigma_S V_S^\top$ where $U_S \in \mathbb{R}^{r\times r}, \Sigma_S \in \mathbb{R}^{r\times r}, V_S \in \mathbb{R}^{n\times r}$. Then, we can rewrite

$$\begin{aligned}\|BS\widehat{A} - \widehat{A}\|_1 &= \|BU_S\Sigma_S V_S^\top \widehat{A} - \widehat{A}\|_1 \\ &= \sum_{l=1}^{n} \|(BU_S\Sigma_S)^l (V_S^\top \widehat{A}) - \widehat{A}^l\|_1 \\ &\geq \sum_{l:\|V_S^l\|_2^2 \leq 2r/n} \|(BU_S\Sigma_S)^l (V_S^\top \widehat{A}) - \widehat{A}^l\|_1. \end{aligned} \tag{17.28}$$

The first equality follows from the SVD of S. The second equality follows from the fact that the ℓ_1-norm of a matrix is the sum of ℓ_1-norms of rows. The third inequality follows since we just look at the cost on a part of the rows.

We use β_l to denote $(BU_S\Sigma_S)^l$. We look at a fixed row l, then the cost on this row is:

$$\begin{aligned}&\|\beta_l (V_S^\top \widehat{A}) - \widehat{A}^l\|_1 \\ =&\|\beta_l (V_S^\top \widehat{A})_{[1:k]} - (\widehat{A}^l)_{[1:k]}\|_1 + \|\beta_l (V_S^\top \widehat{A})_{[k+1:k+n]} - (\widehat{A}^l)_{[k+1:n+k]}\|_1 \\ \geq&\|\beta_l (V_S^\top \widehat{A})_{[1:k]} - (\widehat{A}^l)_{[1:k]}\|_1 + \|\beta_l (V_S^\top \widehat{A})_{[k+1:k+n]}\|_1 - \|(\widehat{A}^l)_{[k+1:n+k]}\|_1 \\ \geq&\|\beta_l (V_S^\top \widehat{A})_{[1:k]} - (\widehat{A}^l)_{[1:k]}\|_1 + \|\beta_l (V_S^\top \widehat{A})_{[k+1:k+n]}\|_1 - 1 \\ \geq&\|\beta_l (V_S^\top \widehat{A})_{[1:k]} - (\widehat{A}^l)_{[1:k]}\|_1 + \|\beta_l V_S^\top\|_1 - 1. \end{aligned} \tag{17.29}$$

where $(V_S^\top \widehat{A})_{[1:k]}$ denotes the first k columns of $(V_S^\top \widehat{A})$, and similarly, $(V_S^\top \widehat{A})_{[k+1:k+n]}$ denotes the last n columns of $(V_S^\top \widehat{A})$. The first equality is because we can compute the sum of ℓ_1 norms on the first k coordinates and ℓ_1 norm on the last n coordinates. The first inequality follows from the triangle inequality. The second inequality follows since the last n columns of $\widehat{A}$ form an identity, so there is exactly one 1 on the last n columns in each row. The third

inequality follows since the last n columns of $\widehat{A}$ form an identity. Let $\mathcal{D}_l$ be a distribution over $D_l \in \mathbb{R}^{(r+1)\times k}$, where

$$D_l = \begin{bmatrix} (V_S^\top \widehat{A})_{[1:k]} \\ (\widehat{A}^l)_{[1:k]} \end{bmatrix}.$$

Let $\mathcal{G}$ be a distribution over $G \in \mathbb{R}^{(r+1)\times k}$ where each entry of G is drawn from i.i.d. $N(0,1)$. According to Lemma 17.6.15, we have

$$D_{\mathrm{TV}}(\mathcal{D}_l, \mathcal{G}) \leq O(k\|(V_S)^l\|_2) + 2^{-\Theta(k)}. \tag{17.30}$$

Let $A = G^{[1:r]}, v = G^{r+1}$. Due to Lemma 17.6.18, with probability at least $1 - 2^{-\Theta(k)}$, $\widehat{\mathcal{E}}(A^\top, V_S, 0.75 - \gamma/2, \gamma)$ happens. Then conditioned on $\widehat{\mathcal{E}}(A^\top, V_S, 0.75 - \gamma/2, \gamma)$, due to Lemma 17.6.20, with probability at most $2^{-\Theta(k)}$, there exists β_l such that

$$\|\beta_l A - v\|_1 + \|\beta_l V_S^\top\|_1 = o(k^\gamma).$$

Combined with Equation (17.30), we can get that for a fixed l, with probability at most $O(k\|(V_S)^l\|_2) + 2^{-\Theta(k)}$, there exists β_l such that

$$\|\beta_l (V_S^\top \widehat{A})_{[1:k]} - (\widehat{A}^l)_{[1:k]}\|_1 + \|\beta_l V_S^\top\|_1 = o(k^\gamma).$$

When $\|(V_S)^l\|_2^2 \leq 2r/n = \Theta(k^{c_1-c_2})$, this probability is at most $\Theta(k^{1+(c_1-c_2)/2}) + 2^{-\Theta(k)}$. Since $\sum_{l=1}^n \|(V_S)^l\|_2^2 = r$, there are at most $n/2$ such l that $\|(V_S)^l\|_2^2 > 2r/n$ which means that there are at least $n/2$ such l that $\|(V_S)^l\|_2^2 \leq 2r/n$. Let s be the number of l such that $\|(V_S)^l\|_2^2 \leq 2r/n$, then $s > n/2$. Let t be a random variable which denotes that the number of l which satisfies $\|(V_S)^l\|_2^2 \leq 2r/n$ and achieve

$$\|\beta_l (V_S^\top \widehat{A})_{[1:k]} - (\widehat{A}^l)_{[1:k]}\|_1 + \|\beta_l V_S^\top\|_1 = o(k^\gamma),$$

at the same time. Then,

$$\mathbb{E}[t] \leq (O(k\|(V_S)^l\|_2) + 2^{-\Theta(k)})s = (O(k\sqrt{2r/n}) + 2^{-\Theta(k)})s.$$

Due to a Markov inequality,

$$\Pr[t > s/2 > n/4] \leq O(k\sqrt{2r/n}) + 2^{-\Theta(k)} = O(k^{1+(c_1-c_2)/2}) + 2^{-\Theta(k)}.$$

The equality follows since $r = \Theta(k^{c_1}), n = \Theta(k^{c_2})$. Plugging it into Equation (17.28), now we can conclude, with probability at least $1 - O(k^{1+(c_1-c_2)/2}) - 2^{-\Theta(k)}$, $\forall B \in \mathbb{R}^{n\times r}$

$$\|BS\widehat{A} - \widehat{A}\|_1 \geq \sum_{l:\|V_S^l\|_2^2 \leq 2r/n} \|(BU_S\Sigma_S)^l(V_S^\top \widehat{A}) - \widehat{A}^l\|_1 \geq n/4 \cdot \Omega(k^\gamma) = \Omega(n \cdot k^\gamma).$$

□

Theorem 17.6.26 (Hardness for row subset selection)**.** *For any $k \geq 1$, any constant $c \geq 1$, let $n = O(k^c)$, and let $\mathcal{A}(k, n)$ denote the same distribution stated in Theorem 17.6.25. For matrix $\widehat{A} \sim \mathcal{A}(k, n)$, with positive probability, there is no algorithm that is able to output $B \in \mathbb{R}^{n\times(n+k)}$ in the row span of any $r = n/2$ rows of $\widehat{A}$ such that*

$$\|\widehat{A} - B\|_1 \leq O(k^{0.5-\alpha}) \min_{\text{rank}-k\ A'} \|A' - \widehat{A}\|_1,$$

where $\alpha \in (0, 0.5)$ is a constant which can be arbitrarily small.

Proof. For convenience, we define $\gamma = 0.5 - \alpha$ which can be an arbitrary constant in $(0, 0.5)$. Since the last n columns of $\widehat{A}$ is an identity matrix, we can fit the first k columns of $\widehat{A}$, so we have

$$\min_{\text{rank}-k\ A'} \|A' - \widehat{A}\|_1 \leq n.$$

We want to argue that $\forall B \in \mathbb{R}^{n\times(k+n)}$ in the row span of any $r = n/2$ rows of $\widehat{A}$,

$$\|\widehat{A} - B\|_1 \geq \Omega(n \cdot k^\gamma).$$

Let $A^\top \in \mathbb{R}^{n\times k}$ be the first k columns of $\widehat{A}$, and let $S \subset [n]$ be a set of indices of chosen rows of $\widehat{A}$ with $k \leq |S| \leq r$. Let $M^S \in \mathbb{R}^{k\times n}$ with the i^{th} column $M^S_i = A_i$ if $i \in S$ and $M^S_i = 0$ otherwise. We use $\widehat{M}^S \in \mathbb{R}^{k\times r}$ to be M^S without those columns of zeros, so it is a random matrix with each entry i.i.d. Gaussian $N(0,1)$. Then the minimum cost of using a matrix in the span of rows of $\widehat{A}$ with index in S to fit $\widehat{A}$ is at least:

$$\sum_{l\notin S} \min_{x_l\in\mathbb{R}^n} \left(\|M^S x_l - A_l\|_1 + \|x_l\|_1 - 1\right).$$

The part of $\|M^S x_l - A_l\|_1$ is just the cost on the l^{th} row of the first k columns of $\widehat{A}$, and the part of $\|x_l\|_1 - 1$ is just the lower bound of the cost on the l^{th} row of the last n columns of $\widehat{A}$.

Claim 17.6.27. *$A, \widehat{M}^S \in \mathbb{R}^{k\times n}, \gamma \in (0, 0.5)$,*

$$\Pr\left[\widehat{\mathcal{E}}(\widehat{M}^S, I_r, 0.75 - \gamma/2, \gamma) \;\middle|\; \widehat{\mathcal{E}}(A, I_n, 0.75 - \gamma/2, \gamma)\right] = 1.$$

Proof. Suppose $\widehat{\mathcal{E}}(A, I_n, 0.75 - \gamma/2, \gamma)$ happens. Since M^S has just a subset of columns of A, $\|M^S\|_2 \leq \|A\|_2 \leq \sqrt{n}$. Notice that $\forall x \in \mathbb{R}^n$ with $\|x\|_1 \leq O(k^\gamma)$ and each non-zero coordinate of x is at most $O(1/k^{0.75-\gamma/2})$, $M^S x \equiv M^S x^S \equiv A x^S$, where $x^S \in \mathbb{R}^n$ has ${x^S}_i = x_i$ if $i \in S$ and ${x^S}_i = 0$ otherwise. Because $\|x^S\|_1 \leq O(k^\gamma)$ and x^S has each coordinate in absolute value at most $O(1/k^{0.75-\gamma/2})$, Ax^S has at most $O(k/\log k)$ coordinates in absolute value at least $\Omega(1/\log k)$. So, $M^S x = Ax^S$ has at most $O(k/\log k)$ coordinates in absolute value at least $\Omega(1/\log k)$. □

We denote $\text{cost}(S,l) = \min_{x_l \in \mathbb{R}^n} \left(\|M^S x_l - A_l\|_1 + \|x_l\|_1 - 1 \right)$. Since $\forall l \notin S$, A_l are independent, and they are independent from M^S, due to Lemma 17.6.20,

$$\Pr\left[\sum_{l \notin S} \text{cost}(S,l) \leq O(n \cdot k^\gamma) \;\middle|\; \widehat{\mathcal{E}}(\widehat{M}^S, I_r, 0.75 - \gamma/2, \gamma) \right] \leq 2^{-\Theta(rk)}. \tag{17.31}$$

Now we just want to upper bound the following:

$$\begin{aligned}
& \Pr\left[\exists S \subset [n], |S| \leq r, \sum_{l \notin S} \text{cost}(S,l) \leq O(n \cdot k^\gamma) \right] \\
\leq & \Pr\left[\exists S \subset [n], |S| \leq r, \sum_{l \notin S} \text{cost}(S,l) \leq O(n \cdot k^\gamma) \;\middle|\; \widehat{\mathcal{E}}(A, I_n, 0.75 - \gamma/2, \gamma) \right] \\
+ & \Pr\left[\neg \widehat{\mathcal{E}}(A, I_n, 0.75 - \gamma/2, \gamma) \right] \\
\leq & \sum_{S \subset [n], |S| \leq r} \Pr\left[\sum_{l \notin S} \text{cost}(S,l) \leq O(n \cdot k^\gamma) \;\middle|\; \widehat{\mathcal{E}}(A, I_n, 0.75 - \gamma/2, \gamma) \right] \\
+ & \Pr\left[\neg \widehat{\mathcal{E}}(A, I_n, 0.75 - \gamma/2, \gamma) \right] \\
\leq & \sum_{S \subset [n], |S| \leq r} \Pr\left[\sum_{l \notin S} \text{cost}(S,l) \leq O(n \cdot k^\gamma) \;\middle|\; \widehat{\mathcal{E}}(A, I_n, 0.75 - \gamma/2, \gamma) \right] + 2^{-\Theta(k)} \\
\leq & \sum_{S \subset [n], |S| \leq r} \Pr\left[\sum_{l \notin S} \text{cost}(S,l) \leq O(n \cdot k^\gamma) \;\middle|\; \widehat{\mathcal{E}}(\widehat{M}^S, I_r, 0.75 - \gamma/2, \gamma) \right] + 2^{-\Theta(k)} \\
\leq & (n+1)^r 2^{-\Theta(rk)} + 2^{-\Theta(k)} \\
\leq & 2^{-\Theta(rk)} + 2^{-\Theta(k)} \\
\leq & 2^{-\Theta(k)}.
\end{aligned}$$

The second inequality follows by a union bound. The third inequality follows by Lemma 17.6.18. The fourth inequality follows by Claim 17.6.27. The fifth inequality is due to Equation (17.31). The sixth inequality follows by $n \leq O(k^c), r = n/2$. Thus, with probability at least $1 - 2^{-\Theta(k)}$,

$\forall B \in \mathbb{R}^{n \times (n+k)}$ which is in the span of any $r \leq n/2$ rows of $\widehat{A}$,

$$\|B - \widehat{A}\|_1 \geq \Omega(n \cdot k^\gamma).$$

Then, we have completed the proof. □

Definition 17.6.3. Given a matrix $A \in \mathbb{R}^{n \times d}$, a matrix $S \in \mathbb{R}^{r \times n}$, $k \geq 1$ and $\gamma \in (0, \frac{1}{2})$, we say that an algorithm $\mathcal{M}(A, S, k, \gamma)$ which outputs a matrix $B \in \mathbb{R}^{n \times r}$ "succeeds", if

$$\|BSA - A\|_1 \leq k^\gamma \cdot \min_{\mathrm{rank}-k \ A'} \|A' - A\|_1,$$

holds.

Theorem 17.6.28 (Hardness for oblivious embedding)**.** *Let Π denote a distribution over matrices $S \in \mathbb{R}^{r \times n}$. For any $k \geq 1$, any constant $\gamma \in (0, \frac{1}{2})$, arbitrary constants $c_1, c_2 > 0$ and $\min(n, d) \geq \Omega(k^{c_2})$, if for all $A \in \mathbb{R}^{n \times d}$, it holds that*

$$\Pr_{S \sim \Pi}[\mathcal{M}(A, S, k, \gamma) \text{ succeeds }] \geq \Omega(1/k^{c_1}).$$

Then r must be at least $\Omega(k^{c_2 - 2c_1 - 2})$.

Proof. We borrow the idea from [NN14, PSW17]. We use Yao's minimax principle [Yao77] here. Let $\mathcal{D}$ be an arbitrary distribution over $\mathbb{R}^{n \times d}$, then

$$\Pr_{A \sim \mathcal{D}, S \sim \Pi}[\mathcal{M}(A, S, k, \gamma)] \geq 1 - \delta.$$

It means that there is a fixed S_0 such that

$$\Pr_{A \sim \mathcal{D}}[\mathcal{M}(A, S_0, k, \gamma)] \geq 1 - \delta.$$

Therefore, we want to find a hard distribution $\mathcal{D}_{\text{hard}}$ that if

$$\Pr_{A\sim\mathcal{D}_{\text{hard}}}[\mathcal{M}(A, S_0, k, \gamma)] \geq 1 - \delta,$$

S_0 must have at least some larger $\text{poly}(k)$ rows.

Here, we just use the distribution $\mathcal{A}(k, \Omega(k^{c_2}))$ described in Theorem 17.6.25 as our hard distribution. We can just fill zeros to expand the size of matrix to $n \times d$. We can complete the proof by using Theorem 17.6.25.

□

Remark 17.6.1. Actually, in Lemma 17.6.18 and Lemma 17.6.20, the reason we need $\beta > \gamma > 0$ is that we want $k^{\beta-\gamma} = \omega(\text{poly}(\log k))$, and the reason we need $\beta + \gamma < 1$ is that we want $k^{\beta+\gamma}\,\text{poly}(\log k) = o(k)$. Thus we can replace all the k^γ by $\sqrt{k}/\,\text{poly}(\log k)$, e.g., $\sqrt{k}/\log^{20} k$, and replace all the k^β by $\sqrt{k}\,\text{poly}(\log k)$ with a smaller $\text{poly}(\log k)$, e.g., $\sqrt{k}\log^{10} k$. Our proofs still work. Therefore, if we replace the approximation ratio in Theorem 17.6.25, Theorem 17.6.26, and Theorem 17.6.28 to be $\sqrt{k}/\log^c k$ where c is a sufficiently large constant, the statements are still correct.

17.7 ℓ_p-Low Rank Approximation

This section presents some fundamental lemmas for ℓ_p-low rank approximation problems. Using these lemmas, all the algorithms described for ℓ_1-low rank approximation problems can be extended to ℓ_p-low rank approximation directly. We only state the important Lemmas in this section, due to most of the proofs in this section being identical to the proofs in Section 17.5.

17.7.1 Definitions

This section is just a generalization of Section 17.5.1 to the ℓ_p setting when $1 < p < 2$.

Definition 17.7.1. Given a matrix $M \in \mathbb{R}^{n\times d}$, if matrix $S \in \mathbb{R}^{m\times n}$ satisfies

$$\|SM\|_p^p \leq c_1\|M\|_p^p,$$

then S has at most c_1-dilation on M.

Definition 17.7.2. Given a matrix $U \in \mathbb{R}^{n\times k}$, if matrix $S \in \mathbb{R}^{m\times n}$ satisfies

$$\forall x \in \mathbb{R}^k, \|SUx\|_p^p \geq \frac{1}{c_2}\|Ux\|_p^p,$$

then S has at most c_2-contraction on U.

Definition 17.7.3. Given matrices $U \in \mathbb{R}^{n\times k}, A \in \mathbb{R}^{n\times d}$, denote $V^* = \arg\min_{V\in\mathbb{R}^{k\times d}} \|UV - A\|_p^p$. If matrix $S \in \mathbb{R}^{m\times n}$ satisfies

$$\forall V \in \mathbb{R}^{k\times d}, \|SUV - SA\|_p^p \geq \frac{1}{c_3}\|UV - A\|_p^p - c_4\|UV^* - A\|_p^p,$$

then S has at most (c_3, c_4)-contraction on (U, A).

Definition 17.7.4. A (c_5, c_6) ℓ_p-subspace embedding for the column space of an $n\times k$ matrix U is a matrix $S \in \mathbb{R}^{m\times n}$ for which all $x \in \mathbb{R}^k$

$$\frac{1}{c_5}\|Ux\|_p^p \leq \|SUx\|_p^p \leq c_6\|Ux\|_p^p.$$

Definition 17.7.5. Given matrices $U \in \mathbb{R}^{n\times k}, A \in \mathbb{R}^{n\times d}$, denote $V^* = \arg\min_{V\in\mathbb{R}^{k\times d}} \|UV - A\|_p^p$. Let $S \in \mathbb{R}^{m\times n}$. If for all $c \geq 1$, and if for any $\widehat{V} \in \mathbb{R}^{k\times d}$ which satisfies

$$\|SU\widehat{V} - SA\|_p^p \leq c \cdot \min_{V\in\mathbb{R}^{k\times d}} \|SUV - SA\|_p^p,$$

it holds that

$$\|U\widehat{V} - A\|_p^p \leq c \cdot c_7 \cdot \|UV^* - A\|_p^p,$$

then S provides a c_7-multiple-regression-cost preserving sketch of (U, A).

Definition 17.7.6. Given matrices $L \in \mathbb{R}^{n \times m_1}, N \in \mathbb{R}^{m_2 \times d}, A \in \mathbb{R}^{n \times d}, k \geq 1$, let

$$X^* = \arg \min_{\text{rank}-k \ X} \|LXN - A\|_p^p.$$

Let $S \in \mathbb{R}^{m \times n}$. If for all $c \geq 1$, and if for any rank $-k$ $\widehat{X} \in \mathbb{R}^{m_1 \times m_2}$ which satisfies

$$\|SL\widehat{X}N - SA\|_p^p \leq c \cdot \min_{\text{rank}-k \ X} \|SLXN - SA\|_p^p,$$

it holds that

$$\|L\widehat{X}N - A\|_p^p \leq c \cdot c_8 \cdot \|LX^*N - A\|_p^p,$$

then S provides a c_8-restricted-multiple-regression-cost preserving sketch of (L, N, A, k).

17.7.2 Properties

Lemma 17.7.1. *Given matrices $A \in \mathbb{R}^{n\times d}, U \in \mathbb{R}^{n\times k}$, let $V^* = \arg\min_{V\in\mathbb{R}^{k\times d}} \|UV - A\|_p^p$. If $S \in \mathbb{R}^{m\times n}$ has at most c_1-dilation on $UV^* - A$, i.e.,*

$$\|S(UV^* - A)\|_p^p \le c_1\|UV^* - A\|_p^p,$$

and it has at most c_2-contraction on U, i.e.,

$$\forall x \in \mathbb{R}^k, \|SUx\|_p^p \ge \frac{1}{c_2}\|Ux\|_p^p,$$

then S has at most $(2^{2p-2}c_2, c_1 + 2^{1-p}\frac{1}{c_2})$-contraction on (U, A), i.e.,

$$\forall V \in \mathbb{R}^{k\times d}, \|SUV - SA\|_p^p \ge \frac{1}{c_2}\|UV - A\|_p^p - (c_1 + \frac{1}{c_2})\|UV^* - A\|_p^p,$$

Proof. Let $A \in \mathbb{R}^{n\times d}, U \in \mathbb{R}^{n\times k}$, and $S \in \mathbb{R}^{m\times n}$ be the same as that described in the lemma. Then $\forall V \in \mathbb{R}^{k\times d}$

$$\begin{aligned}
\|SUV - SA\|_p^p &\ge 2^{1-p}\|SUV - SUV^*\|_p^p - \|SUV^* - SA\|_p^p \\
&\ge 2^{1-p}\|SUV - SUV^*\|_p^p - c_1\|UV^* - A\|_p^p \\
&= 2^{1-p}\|SU(V - V^*)\|_p^p - c_1\|UV^* - A\|_p^p \\
&= 2^{1-p}\sum_{j=1}^{d}\|SU(V - V^*)_j\|_p^p - c_1\|UV^* - A\|_p^p \\
&\ge 2^{1-p}\sum_{j=1}^{d}\frac{1}{c_2}\|U(V - V^*)_j\|_p^p - c_1\|UV^* - A\|_p^p \\
&= 2^{1-p}\frac{1}{c_2}\|UV - UV^*\|_p^p - c_1\|UV^* - A\|_p^p \\
&\ge 2^{2-2p}\frac{1}{c_2}\|UV - A\|_p^p - 2^{1-p}\frac{1}{c_2}\|UV^* - A\|_p^p - c_1\|UV^* - A\|_p^p \\
&= 2^{2-2p}\frac{1}{c_2}\|UV - A\|_p^p - \left((2^{1-p}\frac{1}{c_2} + c_1)\|UV^* - A\|_p^p\right).
\end{aligned}$$

The first inequality follows by Fact 17.7.8. The second inequality follows since S has at most c_1 dilation on $UV^* - A$. The third inequality follows since S has at most c_2 contraction on U. The fourth inequality follows by Fact 17.7.8. □

Lemma 17.7.2. *Given matrices $A \in \mathbb{R}^{n\times d}, U \in \mathbb{R}^{n\times k}$, let $V^* = \arg\min_{V\in\mathbb{R}^{k\times d}} \|UV - A\|_p^p$. If $S \in \mathbb{R}^{m\times n}$ has at most c_1-dilation on $UV^* - A$, i.e.,*

$$\|S(UV^* - A)\|_p^p \leq c_1\|UV^* - A\|_p^p,$$

and has at most c_2-contraction on U, i.e.,

$$\forall x \in \mathbb{R}^k, \|SUx\|_p^p \geq \frac{1}{c_2}\|Ux\|_p^p,$$

then S provides a $2^{p-1}(2c_1c_2 + 1)$-multiple-regression-cost preserving sketch of (U, A), i.e., for all $c \geq 1$, for any $\widehat{V} \in \mathbb{R}^{k\times d}$ which satisfies

$$\|SU\widehat{V} - SA\|_p^p \leq c \cdot \min_{V\in\mathbb{R}^{k\times d}} \|SUV - SA\|_p^p,$$

it has

$$\|U\widehat{V} - A\|_p^p \leq c \cdot 2^{p-1}(2c_1c_2 + 1) \cdot \|UV^* - A\|_p^p,$$

Proof. Let $S \in \mathbb{R}^{m\times n}, A \in \mathbb{R}^{n\times d}, U \in \mathbb{R}^{n\times k}, V^*, \widehat{V} \in \mathbb{R}^{k\times d}$, and c be the same as stated in the lemma.

$$\begin{aligned}
\|U\widehat{V} - A\|_p^p &\leq 2^{2p-2}c_2\|SU\widehat{V} - SA\|_p^p + (2^{p-1} + 2^{2p-2}c_1c_2)\|UV^* - A\|_p^p \\
&\leq 2^{2p-2}c_2c \min_{V\in\mathbb{R}^{k\times d}} \|SUV - SA\|_p^p + (2^{p-1} + 2^{2p-2}c_1c_2)\|UV^* - A\|_p^p \\
&\leq 2^{2p-2}c_2c\|SUV^* - SA\|_p^p + (2^{p-1} + 2^{2p-2}c_1c_2)\|UV^* - A\|_p^p \\
&\leq 2^{2p-2}c_1c_2c\|UV^* - A\|_p^p + (2^{p-1} + 2^{2p-2}c_1c_2)\|UV^* - A\|_p^p \\
&\leq c \cdot 2^{p-1}(1 + 2c_1c_2)\|UV^* - A\|_p^p.
\end{aligned}$$

The first inequality follows by Lemma 17.7.1. The second inequality follows by the guarantee of $\widehat{V}$. The fourth inequality follows since S has at most c_1-dilation on $UV^* - A$. The fifth inequality follows since $c \geq 1$. □

Lemma 17.7.3. *Given matrices $L \in \mathbb{R}^{n \times m_1}, N \in \mathbb{R}^{m_2 \times d}, A \in \mathbb{R}^{n \times d}, k \geq 1$, let*

$$X^* = \arg \min_{\text{rank}-k \ X} \|LXN - A\|_p^p.$$

If $S \in \mathbb{R}^{m \times n}$ has at most c_1-dilation on $LX^*N - A$, i.e.,

$$\|S(LX^*N - A)\|_p^p \leq c_1 \|LX^*N - A\|_p^p,$$

and has at most c_2-contraction on L, i.e.,

$$\forall x \in \mathbb{R}^{m_1} \|SLx\|_p^p \geq \|Lx\|_p^p,$$

then S provides a $2^{p-1}(2c_1c_2+1)$-restricted-multiple-regression-cost preserving sketch of (L, N, A, k), i.e., for all $c \geq 1$, for any rank $-k$ *$\widehat{X} \in \mathbb{R}^{m_1 \times m_2}$ which satisfies*

$$\|SL\widehat{X}N - SA\|_p^p \leq c \cdot \min_{\text{rank}-k \ X} \|SLXN - SA\|_p^p,$$

it has

$$\|L\widehat{X}N - A\|_p^p \leq c \cdot 2^{p-1}(2c_1c_2 + 1) \cdot \|LX^*N - A\|_p^p.$$

Proof. Let $S \in \mathbb{R}^{m \times n}, L \in \mathbb{R}^{n \times m_1}, \widehat{X} \in \mathbb{R}^{m_1 \times m_2}, X^* \in \mathbb{R}^{m_1 \times m_2}, N \in \mathbb{R}^{m_2 \times d}, A \in \mathbb{R}^{n \times d}$ and

$c \geq 1$ be the same as stated in the lemma.

$$\begin{aligned}
\|SL\widehat{X}N - SA\|_p^p &\geq 2^{1-p}\|SL\widehat{X}N - SLX^*N\|_p^p - \|SLX^*N - SA\|_p^p \\
&\geq 2^{1-p}\frac{1}{c_2}\|L(\widehat{X}N - X^*N)\|_p^p - c_1\|LX^*N - A\|_p^p \\
&\geq 2^{2-2p}\frac{1}{c_2}\|L\widehat{X}N - A\|_p^p - 2^{1-p}\frac{1}{c_2}\|LX^*N - A\|_1 - c_1\|LX^*N - A\|_p^p \\
&= 2^{2-2p}\frac{1}{c_2}\|L\widehat{X}N - A\|_p^p - (2^{1-p}\frac{1}{c_2} + c_1)\|LX^*N - A\|_p^p.
\end{aligned}$$

The inequality follows from the Fact 17.7.8. The second inequality follows since S has at most c_2-contraction on L, and it has at most c_1-dilation on $LX^*N - A$. The third inequality follows by Fact 17.7.8.

It follows that

$$\begin{aligned}
\|L\widehat{X}N - A\|_p^p &\leq 2^{2p-2}c_2\|SL\widehat{X}N - SA\|_p^p + (2^{p-1} + 2^{2p-2}c_1c_2)\|LX^*N - A\|_p^p \\
&\leq 2^{2p-2}c_2c \cdot \min_{\text{rank}-k\ X} \|SLXN - SA\|_p^p + (2^{p-1} + 2^{2p-2}c_1c_2)\|LX^*N - A\|_p^p \\
&\leq 2^{2p-2}c_2c \cdot \|SLX^*N - SA\|_p^p + (2^{p-1} + 2^{2p-2}c_1c_2)\|LX^*N - A\|_p^p \\
&\leq 2^{2p-2}cc_1c_2 \cdot \|LX^*N - A\|_p^p + (2^{p-1} + 2^{2p-2}c_1c_2)\|LX^*N - A\|_p^p \\
&\leq c \cdot 2^{p-1}(1 + 2c_1c_2)\|LX^*N - A\|_p^p.
\end{aligned}$$

The first inequality directly follows from the previous one. The second inequality follows from the guarantee of $\widehat{X}$. The fourth inequality follows since S has at most c_1 dilation on $LX^*N - A$. The fifth inequality follows since $c \geq 1$. □

Lemma 17.7.4. *Given matrices $L \in \mathbb{R}^{n\times m_1}, N \in \mathbb{R}^{m_2\times d}, A \in \mathbb{R}^{n\times d}, k \geq 1$, let*

$$X^* = \arg\min_{\text{rank}-k\ X} \|LXN - A\|_p^p.$$

Let $T_1 \in \mathbb{R}^{t_1 \times n}$ have at most c_1-dilation on $LX^*N - A$, and have at most c_2-contraction on L. Let

$$\widetilde{X} = \arg \min_{\text{rank}-k \ X} \|T_1 LXN - T_1 A\|_p^p.$$

Let $T_2^\top \in \mathbb{R}^{t_2 \times d}$ have at most c_1'-dilation on $(T_1 L\widetilde{X}N - T_1 A)^\top$, and at most c_2'-contraction on $N^\top$. Then, for all $c \geq 1$, for any $\text{rank}-k$ $\widehat{X} \in \mathbb{R}^{m_1 \times m_2}$ which satisfies

$$\|T_1(L\widehat{X}N - SA)T_2\|_p^p \leq c \cdot \min_{\text{rank}-k \ X} \|T_1(LXN - A)T_2\|_p^p,$$

it holds that

$$\|L\widehat{X}N - A\|_p^p \leq c \cdot 2^{2p-2}(2c_1c_2 + 1)(2c_1'c_2' + 1) \cdot \|LX^*N - A\|_p^p.$$

Proof. Apply Lemma 17.5.3 for sketching matrix T_2. Then for any $c \geq 1$, any $\text{rank}-k$ $\widehat{X} \in \mathbb{R}^{m_1 \times m_2}$ which satisfies

$$\|T_1(L\widehat{X}N - A)T_2\|_p^p \leq c \cdot \min_{\text{rank}-k \ X} \|T_1(LXN - A)T_2\|_p^p,$$

it has

$$\|T_1(L\widehat{X}N - A)\|_p^p \leq c \cdot 2^{p-1}(2c_1'c_2' + 1) \cdot \|T_1(L\widetilde{X}N - A)\|_p^p.$$

Apply Lemma 17.5.3 for sketch matrix T_1. Then for any $c \geq 1$, any $\text{rank}-k$ $\widehat{X} \in \mathbb{R}^{m_1 \times m_2}$ which satisfies

$$\|T_1(L\widehat{X}N - A)\|_p^p \leq c2^{p-1}(2c_1'c_2' + 1) \cdot \min_{\text{rank}-k \ X} \|T_1(L\widetilde{X}N - A)\|_p^p,$$

it has

$$\|L\widehat{X}N - A\|_p^p \leq c \cdot 2^{2p-2}(2c_1c_2 + 1)(2c_1'c_2' + 1) \cdot \|LX^*N - A\|_p^p.$$

□

Lemma 17.7.5. *Given matrices $M \in \mathbb{R}^{n\times d}, U \in \mathbb{R}^{n\times t}$, $d \geq t = \text{rank}(U), n \geq d \geq r = \text{rank}(M)$. If sketching matrix $S \in \mathbb{R}^{m\times n}$ is drawn from any of the following probability distributions on matrices, with .99 probability, S has at most c_1-dilation on M, i.e.,*

$$\|SM\|_p^p \leq c_1 \|M\|_p^p,$$

and S has at most c_2-contraction on U, i.e.,

$$\forall x \in \mathbb{R}^t, \ \|SUx\|_p^p \geq \frac{1}{c_2}\|Ux\|_p^p,$$

where c_1, c_2 are parameters depend on the distribution over S.

(I) *$S \in \mathbb{R}^{m\times n}$ is a dense matrix with entries drawn from a p-stable distribution: a matrix with i.i.d. standard p-stable random variables. If $m = O(t \log t)$, then $c_1 c_2 = O(\log d)$.*

(II) *$S \in \mathbb{R}^{m\times n}$ is a sparse matrix with some entries drawn from a p-stable distribution: $S = TD$, where $T \in \mathbb{R}^{m\times n}$ has each column drawn i.i.d. from the uniform distribution over standard basis vectors of $\mathbb{R}^m$, and $D \in \mathbb{R}^{n\times n}$ is a diagonal matrix with each diagonal entry drawn from i.i.d. from the standard p-stable distribution. If $m = O(t^5 \log^5 t)$, then $c_1 c_2 = O(t^{2/p} \log^{2/p} t \log d)$. If $m = O((t+r)^5 \log^5(t+r))$, then $c_1 c_2 = O(\min(t^{2/p} \log^{2/p} t \log d, r^{3/p} \log^{3/p} r))$.*

(III) *$S \in \mathbb{R}^{m\times n}$ is a sampling and rescaling matrix (notation $S \in \mathbb{R}^{n\times n}$ denotes a diagonal sampling and rescaling matrix with m non-zero entries): If S samples and reweights $m = O(t \log t \log\log t)$ rows of U, selecting each with probability proportional to the i^{th} row's ℓ_p Lewis weight and reweighting by the inverse probability, then $c_1 c_2 = O(1)$.*

In the above, if we replace S with $\sigma \cdot S$ where $\sigma \in \mathbb{R}\backslash\{0\}$ is any scalar, then the relation between m and $c_1 c_2$ can be preserved.

For (I), it is implied by Lemma E.17, Lemma E.19. Also see from [SW11][3].

For (II), if $m = O(t^5 \log^5 t)$, then $c_1 c_2 = O(t^{2/p} \log^{2/p} t \log d)$ is implied by Corollary 17.5.19 and Lemma 17.7.13 and Theorem 4 in [MM13]. If $m = O((t+r)^5 \log^5(t+r))$, $c_1 c_2 = O(r^{3/p} \log^{3/p} r)$ is implied by [MM13].

For (III), it is implied by [CP15] and Lemma 17.5.21.

[3]Full version.

17.7.3 Tools and inequalities

Lemma 17.7.6 (Lemma 9 in [MM13], Upper Tail Inequality for p-stable Distributions)**.** *Let $p \in (1,2)$ and $m \geq 3$. $\forall i \in [m]$, let X_i be m(not necessarily independent) random variables sampled from D_p, and let $\gamma_i > 0$ with $\gamma = \sum_{i=1}^{m} \gamma_i$. Let $X = \sum_{i=1}^{m} \gamma_i |X_i|^p$. Then for any $t \geq 1$,*

$$\Pr[X \geq t\alpha_p \gamma] \leq \frac{2\log(mt)}{t}.$$

We first review some facts about the p-norm and q-norm,

Fact 17.7.7. *For any $p \geq q > 0$ and any $x \in \mathbb{R}^k$,*

$$\|x\|_p \leq \|x\|_q \leq k^{\frac{1}{q}-\frac{1}{p}} \|x\|_p.$$

We provide the triangle inequality for the p-norm,

Fact 17.7.8. *For any $p \in (1,2)$, for any $x, y \in \mathbb{R}^k$,*

$$\|x+y\|_p \leq \|x\|_p + \|y\|_p, \text{ and } \|x+y\|_p^p \leq 2^{p-1}(\|x\|_p^p + \|y\|_p^p).$$

Fact 17.7.9 (Hölder's inequality)**.** *For any $x, y \in \mathbb{R}^k$, if $\frac{1}{p} + \frac{1}{q} = 1$, then $|x^\top y| \leq \|x\|_p \|y\|_q$.*

We give the definition of a well-conditioned basis for ℓ_p,

Definition 17.7.7. Let $p \in (1,2)$. A basis U for the range of A is (α, β, p)-conditioned if $\|U\|_p \leq \alpha$ and for all $x \in \mathbb{R}^k$, $\|x\|_q \leq \beta \|Ux\|_p$. We will say U is well-conditioned if α and β are low-degree polynomials in k, independent of n.

Proof. We first show an upper bound,

$$\|Ux\|_p \leq \|U\|_p \cdot \|x\|_p \leq \alpha \|x\|_p$$

Then we show a lower bound,

$$\|Ux\|_p \geq \frac{1}{\beta} \|x\|_q$$

For any p and q with $1/p + 1/q = 1$, by Hölder's inequality we have

$$|x^\top y| \leq \|x\|_p \cdot \|y\|_q$$

choosing y to be the vector that has 1 everywhere, $\|x\|_1 \leq \|x\|_p k^{1/q}$ □

17.7.4 Dense p-stable transform

This section states the main tools for the dense p-stable transform. The proof is identical to that for the dense Cauchy transform.

Lemma 17.7.10. *Given matrix $A \in \mathbb{R}^{n\times d}$ and $p \in (1,2)$, define $U^* \in \mathbb{R}^{n\times k}$, $V^* \in \mathbb{R}^{k\times d}$ to be an optimal solution of $\min_{U\in\mathbb{R}^{n\times k}, V\in\mathbb{R}^{k\times d}} \|UV - A\|_p$. Choose a p-stable distribution matrix $S \in \mathbb{R}^{m\times n}$, rescaled by $\Theta(1/m^{1/p})$. Then we have*

$$\|SU^*V^* - SA\|_p^p \lesssim \log(md)\|U^*V^* - A\|_p^p$$

with probability at least $99/100$.

Proof. Let $P(0,1)$ denote the p-stable distribution. Then,

$$\begin{aligned}
\|SU^*V^* - SA\|_p^p \leq & \sum_{i=1}^{d} \|S(U^*V_i^* - A_i)\|_p^p \\
= & \sum_{i=1}^{d}\sum_{j=1}^{m} |\sum_{l=1}^{n} \frac{1}{m} S_{j,l}(U^*V_i^* - A_i)_l|^p && \text{where } S_{j,l} \sim P(0,1) \\
= & \frac{1}{m}\sum_{i=1}^{d}\sum_{j=1}^{m} |\widetilde{w}_{ij}(\sum_{l=1}^{n} |(U^*V_i^* - A_i)_l|^p)^{1/p}|^p && \text{where } \widetilde{w}_{ij} \sim P(0,1) \\
= & \frac{1}{m}\sum_{i=1}^{d}\sum_{j=1}^{m}\sum_{l=1}^{n} |(U^*V_i^* - A_i)_l|^p \cdot |\widetilde{w}_{ij}|^p \\
= & \frac{1}{m}\sum_{i=1}^{d}\sum_{j=1}^{m} \|U^*V_i^* - A_i\|_p^p \cdot w_{i+(j-1)d}^p, && \text{where } w_{i+(j-1)d} \sim |P(0,1)|
\end{aligned}$$

where the last step follows since each w_i can be thought of as a clipped half-p-stable random variable. Define X to be $\sum_{i=1}^{d}\sum_{j=1}^{m} \|U^*V_i^* - A_i\|_p^p \cdot w_{i+(j-1)d}^p$ and γ to be $\sum_{i=1}^{d}\sum_{j=1}^{m} \|U^*V_i^* -$

$A_i\|_p^p$. Then applying Lemma 17.7.6,

$$\Pr[X \geq t\alpha_p\gamma] \leq \frac{2\log(mdt)}{t}.$$

Choosing $t = \Theta(\log(md))$, we have with probability .999,

$$X \lesssim \log(md)\alpha_p\gamma = \log(md)\alpha_p \sum_{i=1}^{d} \|U^*V_i^* - A_i\|_p^p,$$

where the last step follows by definition of γ. Thus, we can conclude that with probability .999, $\|\Pi(U^*V^* - A)\|_p^p \lesssim \log(md)\|U^*V^* - A\|_p^p$. □

Lemma 17.7.11. *Given matrix $A \in \mathbb{R}^{n\times d}$ and $p \in (1,2)$, define $U^* \in \mathbb{R}^{n\times k}$ to be the optimal solution of $\min_{U\in\mathbb{R}^{n\times k}, V\in\mathbb{R}^{k\times d}} \|UV - A\|_p$. Choose a matrix of i.i.d. p-stable random variables $S \in \mathbb{R}^{m\times n}$. Then for all $V \in \mathbb{R}^{k\times n}$, we have*

$$\|SU^*V - SA\|_p^p \gtrsim \|U^*V - A\|_p^p - O(\log(md))\|U^*V^* - A\|_p^p.$$

Lemma 17.7.12. *Let $p \in (1,2)$. Given an (α,β) ℓ_p well-conditioned basis, condition on the following two events,*

1. *For all $x \in \mathcal{N}$, $\|SUx\|_p \gtrsim \|Ux\|_p$.*
2. *For all $x \in \mathbb{R}^k$, $\|SUx\|_p \leq \text{poly}(k)\|Ux\|_p$.*

Then for all $x \in \mathbb{R}^k$, $\|SUx\|_p \gtrsim \|Ux\|_p$.

Proof. The proof is identical to Lemma 17.5.14 in Section 17.5. □

17.7.5 Sparse p-stable transform

This section states the main tools for the sparse p-stable transform. The proof is identical to that of the sparse Cauchy transform.

Lemma 17.7.13. *Let $p \in (1,2)$. Given matrix $A \in \mathbb{R}^{n \times d}$ with U^*, V^* an optimal solution of $\min_{U,V} \|UV - A\|_p$, let $\Pi = \sigma \cdot SC \in \mathbb{R}^{m \times n}$, where $S \in \mathbb{R}^{m \times n}$ has each column vector chosen independently and uniformly from the m standard basis vectors of $\mathbb{R}^m$, where C is a diagonal matrix with diagonals chosen independently from the standard p-stable distribution, and σ is a scalar. Then*

$$\|\Pi U^* V^* - \Pi A\|_p^p \lesssim \sigma \cdot \log(md) \cdot \|U^* V^* - A\|_p^p$$

holds with probability at least .999.

Proof. We define $\Pi = \sigma \cdot SC \in \mathbb{R}^{m \times n}$ as in the statement of the lemma. Then by the

definition of Π, we have,

$$
\begin{aligned}
&\|\Pi(U^*V^* - A)\|_p^p \\
&= \sum_{i=1}^{d} \|SC(U^*V_i^* - A_i)\|_p^p \\
&= \sum_{i=1}^{d} \left\| \begin{bmatrix} S_{11} & S_{12} & \cdots & S_{1n} \\ S_{21} & S_{22} & \cdots & S_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ S_{m1} & S_{m2} & \cdots & S_{mn} \end{bmatrix} \cdot \begin{bmatrix} c_1 & 0 & 0 & 0 \\ 0 & c_2 & 0 & 0 \\ 0 & 0 & \cdots & 0 \\ 0 & 0 & 0 & c_n \end{bmatrix} \cdot (U^*V_i^* - A_i) \right\|_p^p \\
&= \sum_{i=1}^{d} \left\| \begin{bmatrix} c_1S_{11} & c_2S_{12} & \cdots & c_nS_{1n} \\ c_1S_{21} & c_2S_{22} & \cdots & c_nS_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ c_1S_{m1} & c_2S_{m2} & \cdots & c_nS_{mn} \end{bmatrix} \cdot (U^*V_i^* - A_i) \right\|_p^p \\
&= \sum_{i=1}^{d} \left\| \sum_{l=1}^{n} c_l S_{1l} \cdot (U^*V_i^* - A_i)_l, \sum_{l=1}^{n} c_l S_{2l} \cdot (U^*V_i^* - A_i)_l, \cdots, \sum_{l=1}^{n} c_l S_{ml} \cdot (U^*V_i^* - A_i)_l \right\|_p^p \\
&= \sum_{i=1}^{d} \sum_{j=1}^{m} \left| \sum_{l=1}^{n} c_l S_{jl} \cdot (U^*V_i^* - A_i)_l \right|^p \text{ by } aX + bY \text{ and } (|a|^p + |b|^p)^{1/p} Z \text{ are identically distributed} \\
&= \sum_{i=1}^{d} \sum_{j=1}^{m} \left| \widetilde{w}_{ij} \cdot (\sum_{l=1}^{n} |S_{jl}(U^*V_i^* - A_i)_l|^p)^{1/p} \right|^p \text{ where } \widetilde{w}_{ij} \sim P(0,1) \\
&= \sum_{i=1}^{d} \sum_{j=1}^{m} \sum_{l=1}^{n} |S_{jl}(U^*V_i^* - A_i)_l|^p \cdot |\widetilde{w}_{ij}|^p \\
&= \sum_{i=1}^{d} \sum_{j=1}^{m} \sum_{l=1}^{n} |S_{jl}(U^*V_i^* - A_i)_l|^p \cdot w_{i+(j-1)d}^p, \text{ where } w_{i+(j-1)d} \sim |P(0,1)|
\end{aligned}
$$

where the last step follows since each w_i can be thought of as a clipped half-p-stable random variable. Define X to be $\sum_{i=1}^{d} \sum_{j=1}^{m} \sum_{l=1}^{n} |S_{jl}(U^*V_i^* - A_i)_l|^p \cdot w_{i+(j-1)d}^p$ and γ to be $\sum_{i=1}^{d} \sum_{j=1}^{m} \sum_{l=1}^{n} |S_{jl}(U^*V_i^* - A_i)_l|^p$. Then applying Lemma 17.7.6,

$$\Pr[X \geq t\alpha_p\gamma] \leq \frac{2\log(mdt)}{t}.$$

Choosing $t = \Theta(\log(md))$, we have with probability .999,

$$X \lesssim \log(md)\alpha_p\gamma = \log(md)\alpha_p \sum_{i=1}^{d}\sum_{l=1}^{n} |(U^*V_i^* - A_i)_l|^p,$$

where the last steps follows by

$$\begin{aligned}\gamma &= \sum_{i=1}^{d}\sum_{j=1}^{m}\sum_{l=1}^{n} |S_{jl}(U^*V_i^* - A_i)_l|^p \\ &= \sum_{i=1}^{d}\sum_{j=1}^{m}\sum_{l=1}^{n} |S_{jl}|^p|(U^*V_i^* - A_i)_l|^p \\ &= \sum_{i=1}^{d}\sum_{l=1}^{n} |(U^*V_i^* - A_i)_l|^p.\end{aligned}$$

Thus, we can conclude that with probability .999,

$$\|\Pi(U^*V^* - A)\|_p^p \lesssim \log(md)\|U^*V^* - A\|_p^p.$$

□

Lemma 17.7.14. *Given matrix $A \in \mathbb{R}^{n\times d}$ with U^*, V^* an optimal solution of $\min_{U,V} \|UV - A\|_p$, let $\Pi = \sigma \cdot SC \in \mathbb{R}^{m\times n}$, where $S \in \mathbb{R}^{m\times n}$ has each column vector chosen independently and uniformly from the m standard basis vectors of $\mathbb{R}^m$, and where C is a diagonal matrix with diagonals chosen independently from the standard p-stable distribution. Then with probability at least .999, for all $V \in \mathbb{R}^{k\times d}$,*

$$\|\Pi U^*V - \Pi A\|_p^p \geq \|U^*V - A\|_p^p - O(\sigma \log(md))\|U^*V^* - A\|_p^p.$$

Notice that $m = O(k^5 \log^5 k)$ and $\sigma = O((k \log k)^{2/p})$ according to Theorem 4 in [MM13].

17.7.6 ℓ_p-Lewis weights

This section states the main tools for ℓ_p-Lewis weights. The proof is identical to ℓ_1-Lewis weights.

Lemma 17.7.15. *For any $p \in (1,2)$. Given matrix $A \in \mathbb{R}^{n\times d}$, define $U^* \in \mathbb{R}^{n\times k}, V^* \in \mathbb{R}^{k\times d}$ to be an optimal solution of $\min_{U\in\mathbb{R}^{n\times k}, V\in\mathbb{R}^{k\times d}} \|UV - A\|_p$. Choose a diagonal matrix $D \in \mathbb{R}^{n\times n}$ according to the Lewis weights of U^*. We have that*

$$\|DU^*V^* - DA\|_p^p \lesssim \|U^*V^* - A\|_p^p,$$

holds with probability at least .99.

Lemma 17.7.16. *Let $p \in (1,2)$. Given matrix $A \in \mathbb{R}^{n\times d}$, define $U^* \in \mathbb{R}^{n\times k}, V^* \in \mathbb{R}^{k\times d}$ to be an optimal solution of $\min_{U\in\mathbb{R}^{n\times k}, V\in\mathbb{R}^{k\times d}} \|UV - A\|_p$. Choose a sampling and rescaling matrix $D \in \mathbb{R}^{n\times n}$ according to the Lewis weights of U^*. For all $V \in \mathbb{R}^{k\times d}$ we have*

$$\|DU^*V - DA\|_p^p \gtrsim \|U^*V - A\|_p^p - O(1)\|U^*V^* - A\|_p^p,$$

holds with probability at least .99.

17.8 EMD-Low Rank Approximation

In this section we explain how to embed EMD to ℓ_1. For more detailed background on the Earth-Mover Distance(EMD) problem, we refer the reader to [IT03, AIK08, ABIW09, IP11, BIRW16] and [SL09, LOG16]. Section 17.8.1 introduces some necessary notation and definitions for Earth-Mover Distance. Section 17.8.2 presents the main result for the Earth-Mover distance low rank approximation problem.

17.8.1 Definitions

Consider any two non-negative vectors $x, y \in \mathbb{R}_+^{[\Delta]^2}$ such that $\|x\|_1 = \|y\|_1$. Let $\Gamma(x, y)$ be the set of functions $\gamma : [\Delta]^2 \times [\Delta]^2 \to \mathbb{R}_+$, such that for any $i, j \in [\Delta]^2$ we have $\sum_l \gamma(i, l) = x_i$ and $\sum_l \gamma(l, j) = y_j$; that is, Γ is the set of possible "flows" from x to y. Then we define

$$\mathrm{EMD}(x, y) = \min_{\gamma \in \Gamma} \sum_{i,j \in [\Delta]^2} \gamma(i, j) \|i - j\|_1$$

to be the min cost flow from x to y, where the cost of an edge is its ℓ_1 distance.

Using the $\mathrm{EMD}(\cdot, \cdot)$ metric, for general vectors w, we define $\|\cdot\|_{\mathrm{EEMD}}$ distance (which is the same as [SL09]),

$$\|w\|_{\mathrm{EEMD}} = \min_{\substack{x - y + z = w \\ \|x\|_1 = \|y\|_1 \\ x, y \geq 0}} \mathrm{EMD}(x, y) + 2\Delta \|z\|_1.$$

Using $\|\cdot\|_{\mathrm{EEMD}}$ distance, for general matrices $X \in \mathbb{R}^{n \times d}$, we define the $\|\cdot\|_{1,\mathrm{EEMD}}$ distance,

$$\|X\|_{1,\mathrm{EEMD}} = \sum_{i=1}^{d} \|X_i\|_{\mathrm{EEMD}},$$

where X_i denotes the j-th column of matrix X.

17.8.2 Analysis of no contraction and no dilation bound

Lemma 17.8.1. *Given matrix* $A \in \mathbb{R}^{n\times d}$ *and* $U^*, V^* = \underset{U\in\mathbb{R}^{n\times k}, V\in\mathbb{R}^{k\times d}}{\arg\min} \|UV - A\|_{1,\text{EEMD}}$*, there exist sketching matrices* $S \in \mathbb{R}^{m\times n}$ *such that, with probability* .999*, for all* $V \in \mathbb{R}^{k\times d}$*,*

$$\|S(U^*V - A)\|_1 \geq \|U^*V - A\|_{1,\text{EEMD}}$$

holds.

Proof. Using Lemma 1 in [IT03], there exists a constant $C > 0$ such that for all $i \in [d]$,

$$C\|SU^*V_i - SA_i\|_1 \geq \|U^*V_i - A_i\|_{\text{EEMD}}. \tag{17.32}$$

Then taking a summation over all d terms and rescaling the matrix S, we obtain,

$$\sum_{i=1}^{d} \|S(U^*V_i - A_i)\|_1 \geq \|U^*V_i - A_i\|_{\text{EEMD}}$$

which completes the proof. □

Lemma 17.8.2. *Given matrix* $A \in \mathbb{R}^{n\times d}$ *and* $U^*, V^* = \underset{U\in\mathbb{R}^{n\times k}, V\in\mathbb{R}^{k\times d}}{\arg\min} \|UV - A\|_{1,\text{EEMD}}$*, there exist sketching matrices* $S \in \mathbb{R}^{m\times n}$ *such that*

$$\|S(U^*V^* - A)\|_1 \leq O(\log n)\|U^*V^* - A\|_{1,\text{EEMD}}$$

holds with probability at least .999*.*

Proof. Using Lemma 2 in [IT03], we have for any $i \in [d]$,

$$\mathbb{E}[\|SU^*V_i^* - SA_i\|_1] \leq O(\log n)\|U^*V_i^* - A_i\|_{\text{EEMD}}. \tag{17.33}$$

Then using that the expectation is linear, we have

$$\begin{aligned}\mathbb{E}[\|SU^*V^* - SA\|_1] = \ & \mathbb{E}[\sum_{i=1}^{d} \|SU^*V_i^* - SA_i\|_1] \\ = & \sum_{i=1}^{d} \mathbb{E}[\|SU^*V_i^* - SA_i\|_1] \\ \leq & \sum_{i=1}^{d} O(\log n)\|U^*V_i^* - A_i\|_{\mathrm{EEMD}} \qquad \text{by Equation (17.33)} \\ = & O(\log n)\|U^*V^* - A\|_{1,\mathrm{EEMD}}.\end{aligned}$$

Using Markov's inequality, we can complete the proof. □

Theorem 17.8.3. *Given a matrix $A \in \mathbb{R}^{n\times d}$, there exists an algorithm running in* $\mathrm{poly}(k, n, d)$ *time that is able to output $U \in \mathbb{R}^{n\times k}$ and $V \in \mathbb{R}^{k\times d}$ such that*

$$\|UV - A\|_{1,\mathrm{EEMD}} \leq \mathrm{poly}(k) \cdot \log d \cdot \log n \min_{\mathrm{rank}-k \ A_k} \|A_k - A\|_{1,\mathrm{EEMD}}$$

holds with probability .99.

Proof. First using Lemma 17.8.1 and Lemma 17.8.2, we can reduce the original problem into an ℓ_1-low rank approximation problem by choosing $m = \mathrm{poly}(n)$. Second, we can use our ℓ_1-low rank approximation algorithm to solve it. Notice that all of our ℓ_1-low rank approximation algorithms can be applied here. If we apply Theorem 17.4.6, we complete the proof.

□

Our current $\|\cdot\|_{1,\mathrm{EEMD}}$ is column-based. We can also define it to be row-based. Then we get a slightly better result by applying the ℓ_1-low rank algorithm.

Corollary 17.8.4. *Given a matrix $A \in \mathbb{R}^{n \times d}$, there exists an algorithm running in* $\text{poly}(k, n, d)$ *time that is able to output $U \in \mathbb{R}^{n \times k}$ and $V \in \mathbb{R}^{k \times d}$ such that*

$$\|UV - A\|_{1,\text{EEMD}} \leq \text{poly}(k) \cdot \log^2 d \min_{\text{rank}-k \ A_k} \|A_k - A\|_{1,\text{EEMD}}$$

holds with probability .99.

17.9 Hardness

This section presents our hardness results. Section 17.9.1 states several useful tools from literature. Section 17.9.2 shows that, it is **NP-hard** to get some multiplicative error. Assuming ETH is true, we provide a stronger hardness result in Section 17.9.3. Section 17.9.4 extends the result from the rank-1 case to the rank-k case.

17.9.1 Previous results

Definition 17.9.1 ($\|A\|_{\infty\to 1}$,[GV15]). Given matrix $A \in \mathbb{R}^{n\times d}$,

$$\|A\|_{\infty\to 1} = \min_{x\in\{-1,+1\}^n, y\in\{-1,+1\}^d} x^\top A y.$$

The following lemma says that computing $\|A\|_{\infty\to 1}$ for matrix A with entries in $\{-1,+1\}$ is equivalent to computing a best $\{-1,+1\}$ matrix which is an ℓ_1 norm rank-1 approximation to A.

Lemma 17.9.1 (Lemma 3 of [GV15]). *Given matrix $A \in \{-1,+1\}^{n\times d}$,*

$$\|A\|_{\infty\to 1} + \min_{x\in\{-1,+1\}^n, y\in\{-1,+1\}^d} \|A - xy^\top\|_1 = nd.$$

Lemma 17.9.2 (Theorem 2 of [GV15]). *Given $A \in \{-1,+1\}^{n\times d}$, we have*

$$\min_{x\in\{-1,+1\}^n, y\in\{-1,+1\}^d} \|A - xy^\top\|_1 = \min_{x\in\mathbb{R}^n, y\in\mathbb{R}^d} \|A - xy^\top\|_1.$$

Combining with Lemma 17.9.1 and Lemma 17.9.2, it implies that computing $\|A\|_{\infty\to 1}$ for $A \in \{-1,+1\}^{n\times d}$ is equivalent to computing the best ℓ_1 norm rank-1 approximation to the matrix A:

$$\|A\|_{\infty\to 1} + \min_{x\in\mathbb{R}^n, y\in\mathbb{R}^d} \|A - xy^\top\|_1 = nd.$$

Theorem 17.9.3 (**NP-hard** result, Theorem 1 of [GV15]). *Computing $\|A\|_{\infty\to 1}$ for matrix $A \in \{-1,+1\}^{n\times d}$ is* **NP-hard**.

The proof of the above theorem in [GV15] is based on the reduction from MAX-CUT problem. The above theorem implies that computing $\min_{x\in\mathbb{R}^n, y\in\mathbb{R}^d} \|A - xy^\top\|_1$ is also **NP-hard**.

17.9.2 Extension to multiplicative error ℓ_1-low rank approximation

The previous result only shows that solving the exact problem is **NP-hard**. This section presents a stronger hardness result, which says that, it is still **NP-hard** even if the goal is to find a solution that is able to achieve some multiplicative error. The proof in this section and the next section are based on the reduction from the MAX-CUT problem. For recent progress on MAX-CUT problem, we refer the readers to [GW95, BGS98, TSSW00, Hås01, KKMO07, FLP15].

Theorem 17.9.4. *Given* $A \in \{-1, +1\}^{n \times d}$, *computing an* $\widehat{x} \in \mathbb{R}^n, \widehat{y} \in \mathbb{R}^d$ *s.t.*

$$\|A - \widehat{x}^\top \widehat{y}\|_1 \leq (1 + \frac{1}{nd}) \min_{x \in \mathbb{R}^n, y \in \mathbb{R}^d} \|A - x^\top y\|_1$$

is **NP-hard**.

MAX-CUT decision problem: Given a positive integer c^* and an unweighted graph $G = (V, E)$ where V is the set of vertices of G and E is the set of edges of G, the goal is to determine whether there is a cut of G has at least c^* edges.

Lemma 17.9.5. MAX-CUT *decision problem is* **NP-hard**.

We give the definition for the Hadamard matrix,

Definition 17.9.2. The Hadamard matrix H_p of size $p \times p$ is defined recursively : $\begin{bmatrix} H_{p/2} & H_{p/2} \\ H_{p/2} & -H_{p/2} \end{bmatrix}$ with $H_2 = \begin{bmatrix} +1 & +1 \\ +1 & -1 \end{bmatrix}$.

For simplicity, we use H to denote H_p in the rest of the proof.

Recall the reduction shown in [GV15] which is from MAX-CUT to computing $\|\cdot\|_{\infty\to 1}$ for $\{-1,+1\}$ matrices. We do the same thing: for a given graph $G=(V,E)$, we construct a matrix $A\in\{-1,+1\}^{n\times d}$ where $n=p|E|$ and $d=p|V|$. Notice that $p=\text{poly}(|E|,|V|)$ is a parameter which will be determined later, and also p is a power of 2.

We divide the matrix A into $|E|\times|V|$ blocks, and each block has size $p\times p$. For $e\in[|E|]$, if the e^{th} edge has endpoints $i\in[|V|], j\in[|V|]$ and $i<j$, let all the $p\times p$ elements of (e,i) block of A be 1, all the $p\times p$ elements of (e,j) block of A be -1, and all the (e,l) block of A be $p\times p$ Hadamard matrix H for $l\neq i,j$.

Claim 17.9.6 (Lower bound of $\|A\|_{\infty\to 1}$, proof of Theorem 1 of [GV15])**.** *If there is a cut of G with cut size at least c,*

$$\|A\|_{\infty\to 1}\geq 2p^2c-|E||V|p^{3/2}.$$

Claim 17.9.7 (Upper bound of $\|A\|_{\infty\to 1}$, proof of Theorem 1 of [GV15])**.** *If the max cut of G has fewer than c edges,*

$$\|A\|_{\infty\to 1}\leq 2p^2(c-1)+|E||V|p^{3/2}.$$

Remark 17.9.1. In [GV15], they set p as a power of 2 and $p>|E|^2|V|^2$. This implies

$$\forall c\in[|E|], 2p^2(c-1)+|E||V|p^{3/2}<2p^2c-|E||V|p^{3/2}.$$

Therefore, according to Claim 17.9.6 and Claim 17.9.7, if we can know the precise value of $\|A\|_{\infty\to 1}$, we can decide whether G has a cut with cut size at least c^*.

For convenience, we use T^* to denote $\|A\|_{\infty\to 1}$ and use L^* to denote

$$\min_{x\in\mathbb{R}^n, y\in\mathbb{R}^d}\|A-x^\top y\|_1.$$

Also, we use L to denote a $(1+\frac{1}{nd})$ relative error approximation to L^*, which means:

$$L^* \leq L \leq (1+\frac{1}{nd})L^*.$$

We denote T as $nd - L$.

Proof of Theorem 17.9.4. Because $L^* \leq L \leq (1+\frac{1}{nd})L^*$, we have:

$$nd - L^* \geq nd - L \geq nd - (1+\frac{1}{nd})L^*.$$

Due to Lemma 17.9.1 and the definition of T, it has:

$$T^* \geq T \geq T^* - \frac{1}{nd}L^*.$$

Notice that A is a $\{-1,+1\}$ matrix, we have

$$L^* \leq \|A\|_1 \leq 2nd.$$

Thus,

$$T^* \geq T \geq T^* - 2.$$

It means

$$T + 2 \geq T^* \geq T.$$

According to Claim 17.9.11, if G has a cut with cut size at least c, we have:

$$T + 2 \geq T^* \geq 2p^2c - |E||V|p^{3/2}.$$

That is

$$T \geq 2p^2c - |E||V|p^{3/2} - 2.$$

According to Claim 17.9.12, if the max cut of G has fewer than c edges,

$$T \leq T^* \leq 2p^2(c-1) + |E||V|p^{3/2}.$$

Let p be a power of 2 and $p > |E|^3|V|^3$, we have

$$2p^2(c-1) + |E||V|p^{3/2} < 2p^2c - |E||V|p^{3/2} - 2.$$

Therefore, we can decide whether G has a cut with size at least c based on the value of T.

Thus, if we can compute $\widehat{x} \in \mathbb{R}^n, \widehat{y} \in \mathbb{R}^d$ s.t.

$$\|A - \widehat{x}^\top \widehat{y}\|_1 \leq (1 + \frac{1}{nd}) \min_{x \in \mathbb{R}^n, y \in \mathbb{R}^d} \|A - x^\top y\|_1,$$

in polynomial time, it means we can compute L and T in polynomial time, and we can solve MAX-CUT decision problem via the value of T, which leads to a contradiction. □

17.9.3 Using the ETH assumption

The goal of this section is to prove Theorem 17.9.9. We first introduce the definition of 3SAT and Exponential Time Hypothesis(ETH). For the details and background of 3SAT problem, we refer the readers to [AB09].

Definition 17.9.3 (3SAT problem)**.** Given an r variables and m clauses conjunctive normal form CNF formula with size of each clause at most 3, the goal is to decide whether there exists an assignment for the r boolean variables to make the CNF formula be satisfied.

Hypothesis 17.9.8 (Exponential Time Hypothesis (ETH) [IPZ98])**.** *There is a $\delta > 0$ such that* 3SAT *problem defined in Definition 17.9.3 cannot be solved in $O(2^{\delta r})$ running time.*

The main lower bound is stated as follows:

Theorem 17.9.9. *Unless* ETH *(see Hypothesis 17.9.8) fails, for arbitrarily small constant $\gamma > 0$, given some matrix $A \in \{-1, +1\}^{n \times d}$, there is no algorithm can compute $\widehat{x} \in \mathbb{R}^n, \widehat{y} \in \mathbb{R}^d$ s.t.*

$$\|A - \widehat{x}^\top \widehat{y}\|_1 \leq (1 + \frac{1}{\log^{1+\gamma} nd}) \min_{x \in \mathbb{R}^n, y \in \mathbb{R}^d} \|A - x^\top y\|_1,$$

in $(nd)^{O(1)}$ running time.

Before we prove our lower bound, we introduce the following theorem which is used in our proof.

Definition 17.9.4 (MAX-CUT decision problem)**.** Given a positive integer c^* and an unweighted graph $G = (V, E)$ where V is the set of vertices of G and E is the set of edges of G, the goal is to determine whether there is a cut of G has at least c^* edges.

Theorem 17.9.10 (Theorem 6.1 in [FLP15]). *There exist constants $a, b \in (0,1)$ and $a > b$, such that, for a given* MAX-CUT *(see Definition 17.9.4) instance graph $G = (E, V)$ which is an n-vertices 5-regular graph, if there is an algorithm in time $2^{o(n)}$ which can distinguish the following two cases:*

1. *At least one cut of the instance has at least $a|E|$ edges,*
2. *All cuts of the instance have at most $b|E|$ edges,*

then ETH *(see Hypothesis 17.9.8) fails.*

Proof of Theorem 17.9.9. We prove it by contradiction. We assume, for any given $A \in \{-1,+1\}^{n\times d}$, there is an algorithm can compute $\widehat{x} \in \mathbb{R}^n, \widehat{y} \in \mathbb{R}^d$ s.t.

$$\|A - \widehat{x}^\top \widehat{y}\|_1 \leq (1 + \frac{1}{W}) \min_{x\in\mathbb{R}^n, y\in\mathbb{R}^d} \|A - x^\top y\|_1,$$

in time $\mathrm{poly}(nd)$, where $W = \log^{1+\gamma} d$ for arbitrarily small constant $\gamma > 0$. Then, we show the following. There exist constants $a, b \in [0,1], a > b$, for a given MAX-CUT instance $G = (V, E)$ with $|E| = O(|V|)$, such that we can distinguish whether G has a cut with size at least $a|E|$ or all the cuts of G have size at most $b|E|$ in $2^{o(|V|)}$ time, which leads to a contradiction to Theorem 17.9.10.

Recall the reduction shown in [GV15] which is from MAX-CUT to computing $\|\cdot\|_{\infty\to 1}$ for $\{-1,+1\}$ matrices. We do similar things here: for a given graph $G = (V, E)$ where $|E| = O(|V|)$, we construct a matrix $A \in \{-1,+1\}^{n\times d}$ where $n = p|E|$ and $d = p|V|$. Notice that p is a parameter which will be determined later, and also p is a power of 2.

We divide the matrix A into $|E| \times |V|$ blocks, and each block has size $p \times p$. For $e \in [|E|]$, if the e^{th} edge has endpoints $i \in [|V|], j \in [|V|]$ and $i < j$, let all the $p \times p$ elements of (e, i) block of A be 1, all the $p \times p$ elements of (e, j) block of A be -1, and all the (e, l) block of A be $p \times p$ Hadamard matrix H for $l \neq i, j$.

We can construct the matrix in nd time, which is $p^2|E||V|$. We choose p to be the smallest number of power of 2 which is larger than $2^{\frac{2}{a-b}|V|^{1-\frac{\gamma}{10}}}$ for some $\gamma > 0$. Thus, the time for construction of the matrix A is $O(nd) = 2^{O(|V|^{1-\frac{\gamma}{10}})}$.

We will show, if we can compute a $(1 + 1/W)$-approximation to A, we can decide whether G has a cut with size at least $a|E|$ or has no cut with size larger than $b|E|$. For convenience, we use T^* to denote $\|A\|_{\infty \to 1}$ and use L^* to denote

$$\min_{x \in \mathbb{R}^n, y \in \mathbb{R}^d} \|A - x^\top y\|_1.$$

Also, we use L to denote a $(1 + \frac{1}{W})$ relative error approximation to L^*, which means:

$$L^* \leq L \leq (1 + \frac{1}{W})L^*.$$

We denote T as $nd - L$.

Because $L^* \leq L \leq (1 + \frac{1}{W})L^*$, we have:

$$nd - L^* \geq nd - L \geq nd - (1 + \frac{1}{W})L^*.$$

Due to Lemma 17.9.1 and the definition of T, it has:

$$T^* \geq T \geq T^* - \frac{1}{W}L^*.$$

Notice that A is a $\{-1, +1\}$ matrix, we have

$$L^* \leq \|A\|_1 \leq 2nd.$$

Thus,

$$T^* \geq T \geq T^* - 2nd/W.$$

It means

$$T + 2nd/W \geq T^* \geq T.$$

Claim 17.9.11 (Lower bound of $\|A\|_{\infty\to 1}$, proof of Theorem 1 of [GV15])**.** *If there is a cut of G with cut size at least c,*

$$\|A\|_{\infty\to 1} \geq 2p^2c - |E||V|p^{3/2}.$$

Claim 17.9.12 (Upper bound of $\|A\|_{\infty\to 1}$, proof of Theorem 1 of [GV15])**.** *If the max cut of G has fewer than c edges,*

$$\|A\|_{\infty\to 1} \leq 2p^2(c-1) + |E||V|p^{3/2}.$$

According to Claim 17.9.11, if G has a cut with cut size at least $a|E|$, we have:

$$T + 2nd/W \geq T^* \geq 2p^2a|E| - |E||V|p^{3/2}.$$

That is

$$T \geq 2p^2a|E| - |E||V|p^{3/2} - 2nd/W. \tag{17.34}$$

According to Claim 17.9.12, if the max cut of G has fewer than $b|E|$ edges,

$$T \leq T^* \leq 2p^2b|E| + |E||V|p^{3/2}. \tag{17.35}$$

Using these conditions $p \geq 2^{\frac{2}{a-b}|V|^{1-\frac{\gamma}{10}}}, d = p|V|, W \geq \log^{1+\gamma} d$, we can lower bound $|W|$ by $|V|$ up to some constant,

$$\begin{aligned}
W \geq\ & \log^{1+\gamma} d && \text{by } W \geq \log^{1+\gamma} d \\
=\ & \log^{1+\gamma}(p|V|) && \text{by } d = p|V| \\
=\ & (\log|V| + \log p)^{1+\gamma} \\
\geq\ & (\log|V| + \frac{2}{a-b}|V|^{1-\frac{\gamma}{10}})^{1+\gamma} && \text{by } p \geq 2^{\frac{2}{a-b}|V|^{1-\frac{\gamma}{10}}} \\
\geq\ & \frac{2}{a-b}|V|. && \text{by } (1-\gamma/10)(1+\gamma) > 1 \text{ for } \gamma \text{ small enough} \qquad (17.36)
\end{aligned}$$

Thus, we can upper bound $1/W$ in the following sense,

$$\frac{1}{W} \leq \frac{a-b}{2|V|} \leq \frac{a-b}{|V|} - p^{-\frac{1}{2}}, \qquad (17.37)$$

where the first inequality follows by Equation (17.36) and the second inequality follows by $p \geq 2^{\frac{2}{a-b}|V|^{1-\frac{\gamma}{10}}}$, γ is sufficient small, and $|V|$ is large enough.

Now, we can conclude,

$$\begin{aligned}
& \frac{1}{W} \leq \frac{a-b}{|V|} - p^{-\frac{1}{2}} \\
\iff\ & p^2|E||V|/W \leq (a-b)p^2|E| - |E||V|p^{\frac{3}{2}} \\
& \text{by multiplying } p^2|E||V| \text{ on both sides} \\
\iff\ & 2nd/W \leq 2(a-b)p^2|E| - 2|E||V|p^{\frac{3}{2}} \\
& \text{by multiplying 2 on both sides and } p^2|E||V| = nd \\
\iff\ & 2p^2b|E| + |E||V|p^{3/2} < 2p^2a|E| - |E||V|p^{3/2} - 2nd/W, \qquad (17.38) \\
& \text{by adding } 2p^2b|E| + |E||V|p^{3/2} - 2nd/W \text{ on both sides}
\end{aligned}$$

which implies that Equation (17.38) is equivalent to Equation (17.37). Notice that the LHS of (17.38) is exactly the RHS of (17.35) and the RHS of (17.38) is exactly the RHS of (17.34). Therefore, we can decide whether G has a cut with size larger than $a|E|$ or has no cut with size larger than $b|E|$.

Thus, if we can compute $\widehat{x} \in \mathbb{R}^n, \widehat{y} \in \mathbb{R}^d$ s.t.

$$\|A - \widehat{x}^\top \widehat{y}\|_1 \leq (1 + \frac{1}{\log^{1+\gamma} d}) \min_{x \in \mathbb{R}^n, y \in \mathbb{R}^d} \|A - x^\top y\|_1,$$

in poly(nd) time, which means we can compute L and T in poly(nd) time. Notice that $nd = p^2|E||V|, |E| = O(|V|), p \geq 2^{\frac{2}{a-b}|V|^{1-\frac{\gamma}{10}}}$, it means poly$(nd) = 2^{O(|V|^{1-\frac{\gamma}{10}})}$. Because we decide whether G has a cut with size larger than $a|E|$ or has no cut with size larger than $b|E|$ via the value of T, we can solve it in $2^{O(|V|^{1-\frac{\gamma}{10}})}$ time which leads to a contradiction to Theorem 17.9.10. □

17.9.4 Extension to the rank-k case

This section presents a way of reducing the rank-k case to the rank-1 case. Thus, we can obtain a lower bound for general $k \geq 1$ under ETH.

Theorem 17.9.13. *For any constants $c_1 > 0, c_2 > 0$ and $c_3 > 0$, and any constant $c_4 \geq 10(c_1 + c_2 + c_3 + 1)$, given any matrix $A \in \mathbb{R}^{n \times n}$ with absolute value of each entry bounded by n^{c_1}, we define a block diagonal matrix $\widetilde{A} \in \mathbb{R}^{(n+k-1)\times(n+k-1)}$ as*

$$\widetilde{A} = \begin{bmatrix} A & 0 & 0 & \cdots & 0 \\ 0 & B & 0 & \cdots & 0 \\ 0 & 0 & B & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & \cdots & B \end{bmatrix},$$

where $B = n^{c_4}$. If $\widehat{A}$ is an ℓ_1-norm rank-k C-approximation solution to $\widetilde{A}$, i.e.,

$$\|\widehat{A} - \widetilde{A}\|_1 \leq C \cdot \min_{\mathrm{rank}-k\ \widehat{A}'} \|\widehat{A}' - \widetilde{A}\|_1,$$

where $C \in [1, n^{c_3}]$, then there must exist $j^* \in [n]$ such that

$$\min_{v \in \mathbb{R}^n} \|\widehat{A}_{j^*}^{[1:n]} v^\top - A\|_1 \leq C \cdot \min_{u,v \in \mathbb{R}^n} \|uv^\top - A\|_1 + 1/n^{c_2},$$

i.e., the first n coordinates of the column j^* of $\widehat{A}$ can give an ℓ_1-norm rank-1 C-approximation to A.

Proof. The first observation is that because we can use a rank-1 matrix to fit A and use a rank-$(k-1)$ matrix to fit other Bs, we have

$$\min_{\mathrm{rank}-k\ \widehat{A}'} \|\widehat{A}' - \widetilde{A}\|_1 \leq \min_{u,v \in \mathbb{R}^n} \|uv^\top - A\|_1 \leq \|A\|_1. \tag{17.39}$$

Claim 17.9.14. *Let $\widehat{A}$ denote the* rank-k *C-approximate solution to $\widetilde{A}$. Let $Z \in \mathbb{R}^{(n+k-1)\times(k-1)}$ denote the rightmost $k-1$ columns of $\widehat{A}$, then,* $\text{rank}(Z) = k-1$.

Proof. Consider the $(k-1)\times(k-1)$ submatrix $Z^{[n+1:n+k-1]}$ of Z. Each element on the diagonal of this submatrix should be at least $B - C\|A\|_1$, and each element not on the diagonal of the submatrix should be at most $C\|A\|_1$. Otherwise $\|\widehat{A} - \widetilde{A}\|_1 > C\|A\|_1$ which will lead to a contradiction. Since $B = n^{c_4}$ is sufficiently large, $Z^{[n+1:n+k-1]}$ is diagonally dominant. Thus $\text{rank}(Z) \geq \text{rank}(Z^{[n+1:n+k-1]}) = k-1$. Because Z only has $k-1$ columns, $\text{rank}(Z) = k-1$. □

Claim 17.9.15. $\forall x \in \mathbb{R}^{k-1}, i \in [n], \exists j \in \{n+1, n+2, \cdots, n+k-1\}$ *such that,*

$$\frac{|(Zx)_j|}{|(Zx)_i|} \geq \frac{B}{2(k-1)C\|A\|_1}.$$

Proof. Without loss of generality, we can let $\|x\|_1 = 1$. Thus, there exists j such that $|x_j| \geq \frac{1}{k-1}$. So we have

$$\begin{aligned}
|(Zx)_{n+j}| &= |\sum_{i=1}^{k-1} Z_{n+j,i}x_i| \\
&\geq |Z_{n+j,j}x_j| - \sum_{i\neq j} |Z_{n+j,i}x_i| \\
&\geq (B - C\|A\|_1)|x_j| - \sum_{i\neq j} |x_i|C\|A\|_1 \\
&\geq (B - C\|A\|_1)/(k-1) - C\|A\|_1 \\
&\geq \frac{B}{2(k-1)}.
\end{aligned}$$

The second inequality follows because $|Z_{n+j,j}| \geq B - C\|A\|_1$ and $\forall i \neq j, |Z_{n+j,i}| \leq C\|A\|_1$ (otherwise $\|\widehat{A} - \widetilde{A}\|_1 > C\|A\|_1$ which leads to a contradiction.) The third inequality follows

from $|x_j| > 1/(k-1)$ and $\|x\|_1 = 1$. The fourth inequality follows since B is large enough such that $\frac{B}{2(k-1)} \geq \frac{C\|A\|_1}{k-1} + C\|A\|_1$.

Now we consider any $q \in [n]$. We have

$$|(Zx)_q| = \sum_{i=1}^{k-1} |Z_{q,i}x_i| \leq \max_{i\in[k-1]} |Z_{q,i}| \cdot \sum_{i=1}^{k-1} |x_i| \leq C\|A\|_1.$$

The last inequality follows that $\|x\|_1 = 1$ and $\forall i \in [k-1], Z_{q,i} \leq C\|A\|_1$. Otherwise, $\|\widehat{A} - \widetilde{A}\|_1 > C\|A\|_1$ which will lead to a contradiction.

Look at $|(Zx)_{n+j}|/|(Zx)_q|$, it is greater than $\frac{B}{2(k-1)C\|A\|_1}$.

□

We now look at the submatrix $\widehat{A}^{[1:n]}_{[1:n]}$, we choose $i^*, j^* \in [n]$ such that

$$|\widehat{A}_{i^*,j^*}| \geq 1/n^{c_2-2}.$$

If there is no such (i^*, j^*), it means that we already found a good rank-1 approximation to A

$$\begin{aligned}
\|\mathbf{0} - A\|_1 &\leq \|\mathbf{0} - \widehat{A}^{[1:n]}_{[1:n]}\|_1 + \|\widehat{A}^{[1:n]}_{[1:n]} - A\|_1 \\
&\leq \|\mathbf{0} - \widehat{A}^{[1:n]}_{[1:n]}\|_1 + \|\widehat{A} - \widetilde{A}\|_1 \\
&\leq 1/n^{c_2} + \|\widehat{A} - \widetilde{A}\|_1 \\
&\leq 1/n^{c_2} + C \min_{\text{rank}-k\ \widehat{A}'} \|\widehat{A}' - \widetilde{A}\|_1 \\
&\leq 1/n^{c_2} + C \min_{u,v\in\mathbb{R}^n} \|uv^\top - A\|_1,
\end{aligned}$$

where $\mathbf{0}$ is an $n \times n$ all zeros matrix. The second inequality follows since $\widehat{A}^{[1:n]}_{[1:n]} - A$ is a submatrix of $\widehat{A} - \widetilde{A}$. The third inequality follows since each entry of $\widehat{A}^{[1:n]}_{[1:n]}$ should be

no greater than $1/n^{c_2-2}$ (otherwise, we can find (i^*, j^*)). The last inequality follows from equation 17.39.

Claim 17.9.16. *$\widehat{A}_{j^*}$ is not in the column span of Z, i.e.,*

$$\forall x \in \mathbb{R}^{k-1}, \widehat{A}_{j^*} \neq Zx.$$

Proof. If there is an x such that $\widehat{A}_{j^*} = Zx$, it means $(Zx)_{i^*} = \widehat{A}_{i^*,j^*} \geq 1/n^{c_2-2}$. Due to Claim 17.9.15, there must exist $i' \in \{n+1, n+2, \cdots, n+k-1\}$ such that $(Zx)_{i'} \geq \frac{B}{2(k-1)C\|A\|_1 n^{c_2-2}}$. Since B is sufficiently large, $\widehat{A}_{i',j^*} = (Zx)_{i'} > C\|A\|_1$ which implies that $\|\widehat{A} - \widetilde{A}\|_1 > C\|A\|_1$, and so leads to a contradiction. □

Due to Claim 17.9.14 and Claim 17.9.16, the dimension of the subspace spanned by $\widehat{A}_{j^*}$ and the column space of Z is k. Since $\widehat{A}$ has rank at most k, it means that each column of $\widehat{A}$ can be written as a linear combination of $\widehat{A}_{j^*}$ and the columns of Z.

Now consider the j^{th} column $\widehat{A}_j$ of $\widehat{A}$ for $j \in [n]$. We write it as

$$\widehat{A}_j = \alpha_j \cdot \widehat{A}_{j^*} + Zx^j.$$

Claim 17.9.17. $\forall j \in [n], \alpha_j \leq 2C\|A\|_1 n^{c_2+2}$.

Proof. Otherwise, suppose $\alpha_j > 2C\|A\|_1 n^{c_2+2}$. We have

$$\begin{aligned} |(Zx^j)_{i^*}| &\geq \alpha_j \cdot |\widehat{A}_{i^*,j^*}| - |\widehat{A}_{i^*,j}| \\ &\geq \alpha_j \cdot \frac{1}{n^{c_2-2}} - |\widehat{A}_{i^*,j}| \\ &\geq \frac{1}{2}\alpha_j \cdot \frac{1}{n^{c_2-2}}. \end{aligned}$$

The second inequality follows from $|\widehat{A}_{i^*,j^*}| \geq 1/n^{c2-2}$. The third inequality follows from $|\widehat{A}_{i^*,j}| \leq \|A\|_1$ and $\frac{1}{2}\alpha_j \cdot \frac{1}{n^{c_2-2}} \geq C\|A\|_1 \geq \|A\|_1$.

Due to Claim 17.9.15, there exists $i \in \{n+1, n+2, \cdots, n+k-1\}$ such that $|(Zx^j)_i| \geq \frac{B}{2(k-1)C\|A\|_1} \cdot \frac{1}{2}\alpha_j \cdot \frac{1}{n^{c_2-2}}$. For sufficiently large B, we can have $|(Zx^j)_i| \geq \alpha_j B^{1/2}$. Then we look at

$$\begin{aligned}
|\widehat{A}_{i,j}| &\geq |(Zx^j)_i| - \alpha_j |\widehat{A}_{i,j^*}| \\
&\geq \alpha_j (B^{1/2} - C\|A\|_1) \\
&\geq \alpha_j \frac{1}{2} B^{1/2}.
\end{aligned}$$

The second inequality follows by $|\widehat{A}_{i,j^*}| \leq C\|A\|_1$, otherwise $\|\widehat{A} - \widetilde{A}\|_1 > C\|A\|_1$ which will lead to a contradiction. The third inequality follows that B is sufficient large that $\frac{1}{2}B^{1/2} > C\|A\|_1$.

Since $|\widehat{A}_{i,j}| \geq \alpha_j \frac{1}{2} B^{1/2} > C\|A\|_1$, it contradicts to the fact $\|\widehat{A} - \widetilde{A}\|_1 \leq C\|A\|_1$.

Therefore, $\forall j \in [n], \alpha_j \leq 2C\|A\|_1 n^{c_2+2}$. □

Claim 17.9.18. $\forall j \in [n], i \in \{n+1, n+2, \cdots, n+k-1\}, |(Zx^j)_i| \leq 4C^2\|A\|_1^2 n^{c_2+2}$

Proof. Consider $j \in [n], i \in \{n+1, n+2, \cdots, n+k-1\}$, we have

$$\begin{aligned}
|(Zx^j)_i| &\leq |\widehat{A}_{i,j}| + \alpha_j |\widehat{A}_{i,j^*}| \\
&\leq C\|A\|_1 + \alpha_j \cdot C\|A\|_1 \\
&\leq 4C^2\|A\|_1^2 n^{c_2+2}.
\end{aligned}$$

The second inequality follows by $|\widehat{A}_{i,j}| \leq C\|A\|_1$ and $|\widehat{A}_{i,j^*}| \leq C\|A\|_1$, otherwise the $\|\widehat{A} - \widetilde{A}\|_1$ will be too large and leads to a contradiction. The third inequality is due to $\alpha_j + 1 \leq 4C\|A\|_1 n^{c_2+2}$ via Claim 17.9.17. □

Claim 17.9.19. $\forall j \in [n], \|\widehat{A}_j^{[1:n]} - \alpha_j \cdot \widehat{A}_{j^*}^{1:n}\|_\infty \le 1/n^{c_2-2}$

Proof. Due to Claim 17.9.18 and Claim 17.9.15, $\forall i, j \in [n]$, we have

$$|(Zx^j)_i| \le \frac{4C^2\|A\|_1^2 n^{c_2+2}}{B/(2(k-1)C\|A\|_1)} \le 1/B^{1/2}.$$

The second inequality follows for a large enough B.

Therefore, $\forall i, j \in [n]$,

$$|\widehat{A}_{i,j} - \alpha_j \cdot \widehat{A}_{i,j^*}| \le |(Zx^j)_i| \le 1/B^{1/2} \le 1/n^{c_2-2}.$$

The last inequality follows since B is large enough.

□

Now, let us show that $\widehat{A}_{j^*}^{1:n}$ can provide a good rank-1 approximation to A:

$$\begin{aligned}
\|\widehat{A}_{j^*}^{1:n}\alpha^\top - A\|_1 &\le \|\widehat{A}_{j^*}^{1:n}\alpha^\top - \widehat{A}_{[1:n]}^{[1:n]}\|_1 + \|\widehat{A}_{[1:n]}^{[1:n]} - A\|_1 \\
&= \sum_{j=1}^{n} \|\alpha_j \widehat{A}_{j^*} - \widehat{A}_j^{[1:n]}\|_1 + \|\widehat{A}_{[1:n]}^{[1:n]} - A\|_1 \\
&\le n^2 \cdot 1/n^{c_2-2} + \|\widehat{A}_{[1:n]}^{[1:n]} - A\|_1 \\
&\le 1/n^{c_2} + \|\widehat{A} - \widetilde{A}\|_1 \\
&\le 1/n^{c_2} + C \min_{u,v\in\mathbb{R}^n} \|uv^\top - A\|_1.
\end{aligned}$$

The first inequality follows by triangle inequality. The first equality is due to the linearity of ℓ_1 norm. The second inequality is due to Claim 17.9.19. The third inequality follows since $\widehat{A}_{[1:n]}^{[1:n]} - A$ is a submatrix of $\widehat{A} - \widetilde{A}$. The fourth inequality is due to the equation 17.39.

□

17.10 Experiments and Discussions

In this section, we provide some counterexamples for the other heuristic algorithms such that, for those examples, the heuristic algorithms can output a solution with a very "bad" approximation ratio, i.e., n^c, where $c > 0$ and the input matrix has size $n \times n$. We not only observe that heuristic algorithms sometimes have very bad performance in practice, but also give a proof in theory.

17.10.1 Setup

We provide some details of our experimental setup. We obtained the R package of [KK05, Kwa08, BDB13] from https://cran.r-project.org/web/packages/pcaL1/index.html. We also implemented our algorithm and the r1-pca algorithm [DZHZ06] using the R language. The version of the R language is 3.0.2. We ran experiments on a machine with Intel X5550@2.67GHz CPU and 24G memory. The operating system of that machine is Linux Ubuntu 14.04.5 LTS. All the experiments were done in single-threaded mode.

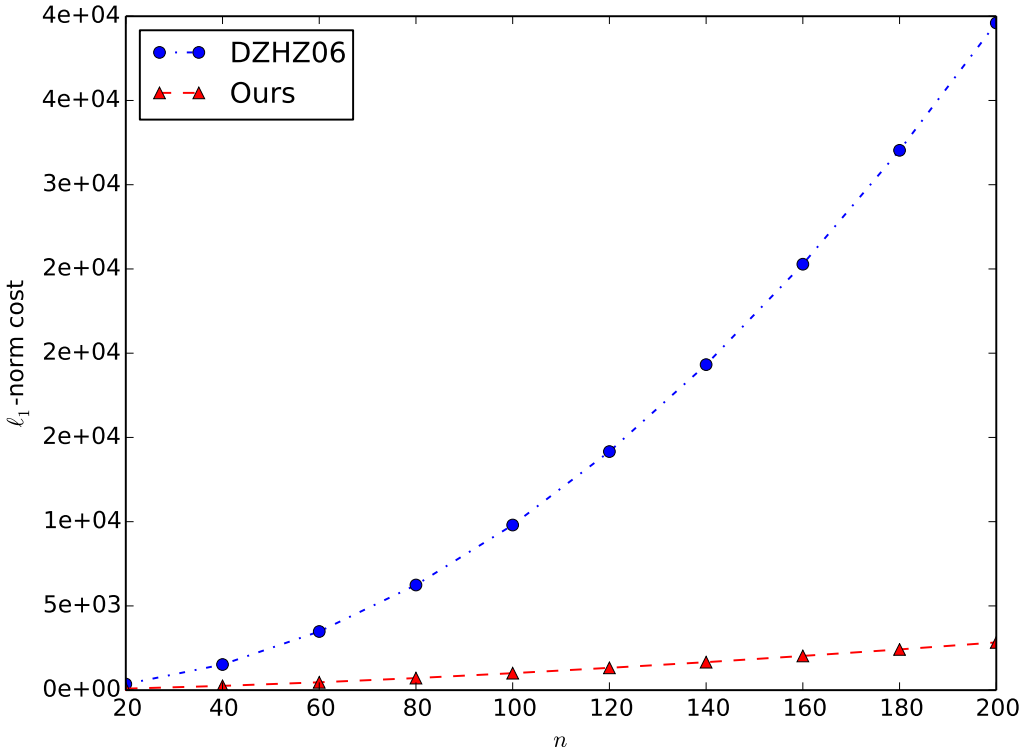

Figure 17.1: The x-axis is n where $A \in \mathbb{R}^{n \times n}$, and the y-axis is $\|A' - A\|_1$ where $\text{rank}(A') = k$. This figure shows the performance of both our algorithm and [DZHZ06] on input matrix A defined as Equation (17.40).

17.10.2 Counterexample for [DZHZ06]

The goal is to find a rank $k = 1$ approximation for matrix A. For any $\epsilon \in [0, 0.5)$, we define $A \in \mathbb{R}^{n \times n}$ as

$$A = \begin{bmatrix} n^{1.5+\epsilon} & 0 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & B \end{bmatrix}, \tag{17.40}$$

where $B \in \mathbb{R}^{(n-1) \times (n-1)}$ is all 1s matrix. It is immediate that the optimal cost is at most $n^{1.5+\epsilon}$. However, using the algorithm in [DZHZ06], the cost is at least $\Omega(n^2)$. Thus, we

can conclude, using algorithm [DZHZ06] to solve ℓ_1 low rank approximation problem on A cannot achieve an approximation ratio better than $n^{0.5-\epsilon}$.

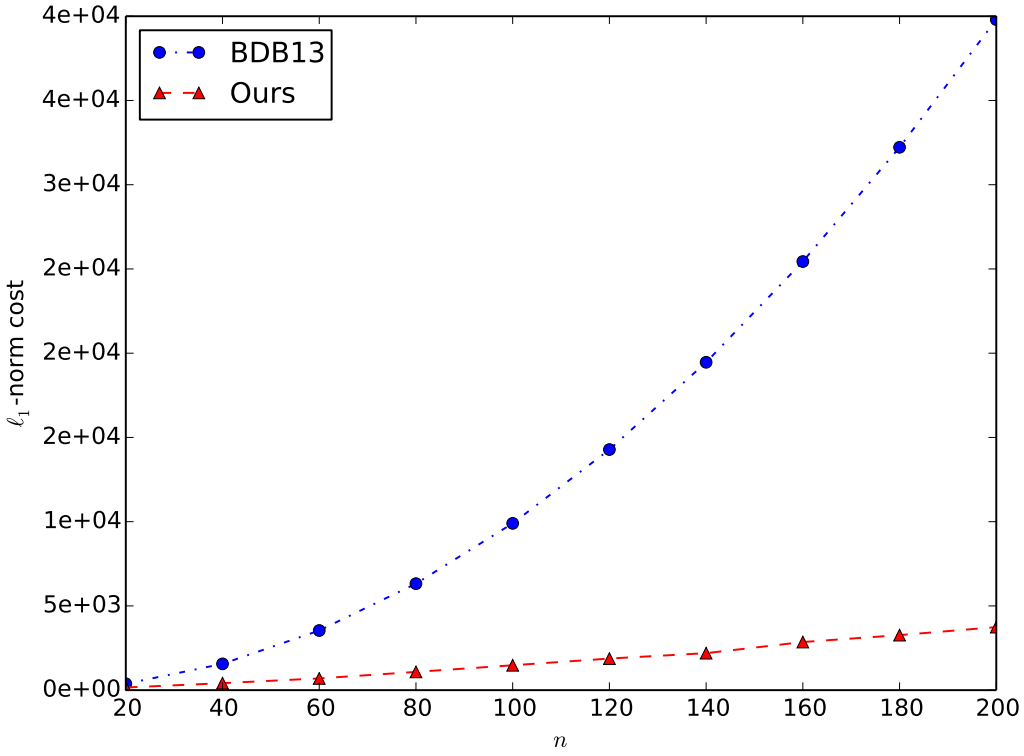

Figure 17.2: The x-axis is n where $A \in \mathbb{R}^{n \times n}$, and the y-axis is $\|A' - A\|_1$ where $\text{rank}(A') = k$. This figure shows the performance of both our algorithm and [BDB13] on input matrix A defined as Equation (17.41).

17.10.3 Counterexample for [BDB13]

The goal is to find a rank $k = 1$ approximation for matrix A. The input matrix $A \in \mathbb{R}^{d \times d}$ for algorithm [BDB13] is defined to be,

$$A = \begin{bmatrix} n^{1.5} & 0 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & B \end{bmatrix}, \tag{17.41}$$

where $B \in \mathbb{R}^{(n-1) \times (n-1)}$ is an all 1s matrix. It is immediate that the optimal cost is at most $n^{1.5}$. Now, let us look at the procedure of [BDB13]. Basically, the algorithm described

in [BDB13] is that they first find a rank $n-1$ approximation via a best ℓ_1-fit hyperplane algorithm, then they rotate it based on the right singular vectors of the rank $n-1$ approximation matrix, and next they recursively do the same thing for the rotated matrix which has only $n-1$ columns.

When running their algorithm on A, they will fit an arbitrary column except the first column of A. Without loss of generality, it just fits the last column of A. After the rotation, the matrix will be an $n \times (n-1)$ matrix:

$$\begin{bmatrix} n^{1.5} & 0 & 0 & \cdots & 0 \\ 0 & \sqrt{n-2} & 0 & \cdots & 0 \\ 0 & \sqrt{n-2} & 0 & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & \sqrt{n-2} & 0 & \cdots & 0 \end{bmatrix}.$$

Then, after the t^{th} iteration for $t < (n-1)$, they will get an $n \times (n-t)$ matrix:

$$\begin{bmatrix} n^{1.5} & 0 & 0 & \cdots & 0 \\ 0 & \sqrt{n-2} & 0 & \cdots & 0 \\ 0 & \sqrt{n-2} & 0 & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & \sqrt{n-2} & 0 & \cdots & 0 \end{bmatrix}.$$

This means that their algorithm will run on an $n \times 2$ matrix:

$$\begin{bmatrix} n^{1.5} & 0 \\ 0 & \sqrt{n-2} \\ 0 & \sqrt{n-2} \\ \cdots & \cdots \\ 0 & \sqrt{n-2} \end{bmatrix},$$

in the last iteration. Notice that $n \times \sqrt{n-2} < n^{1.5}$. This means that their algorithm will fit the first column which implies that their algorithm will output a rank-1 approximation to A by just fitting the first column of A. But the cost of this rank-1 solution is $(n-1)^2$. Since the optimal cost is at most $n^{1.5}$, their algorithm cannot achieve an approximation ratio better than $n^{0.5}$.

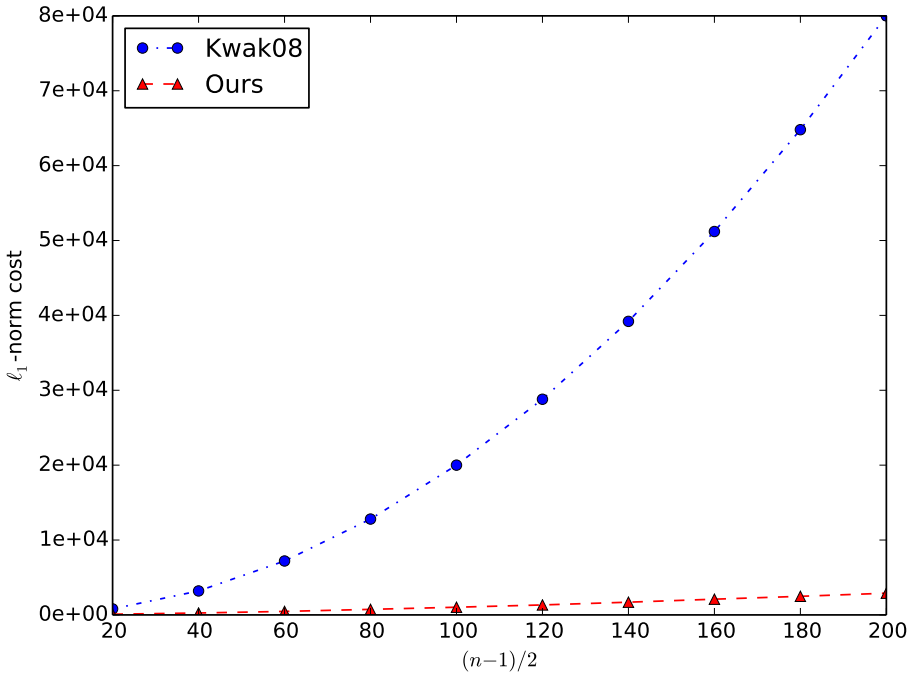

Figure 17.3: The x-axis is n where $A \in \mathbb{R}^{n \times n}$, and the y-axis is $\|A' - A\|_1$ where $\text{rank}(A') = k$. This figure shows the performance of both our algorithm and [Kwa08] on input matrix A defined as Equation (17.42). Algorithm [Kwa08] has two ways of initialization, which have similar performance on matrix A.

17.10.4 Counterexample for [Kwa08]

We show that the algorithm [Kwa08] cannot achieve an approximation ratio better than $\Theta(n)$ on the matrix $A \in \mathbb{R}^{(2n+1)\times(2n+1)}$ defined as,

$$A = \begin{bmatrix} n^{1.5} & 0 & 0 \\ 0 & B & 0 \\ 0 & 0 & B \end{bmatrix}, \tag{17.42}$$

where B is an $n \times n$ matrix that contains all 1s. We consider the rank-2 approximation problem for this input matrix A. The optimal cost is at most $n^{1.5}$.

We run their algorithm. Let x_0 denote the initial random unit vector. Consider the sign vector $s \in \{\pm 1\}^{2n+1}$ where each entry is the sign of the inner product between x_0 and each column of A. There are only three possibilities,

$$s = \begin{cases} (1, \{1\}^n, \{1\}^n) \\ (1, \{1\}^n, \{-1\}^n) \\ (1, \{-1\}^n, \{1\}^n) \end{cases}.$$

Case I, $s = (1, \{1\}^n, \{1\}^n)$. Define $\widehat{u} = \sum_{i=1}^{2n+1} s_i \cdot A_i = (n^{1.5}, n, \cdots, n)$. Let $u = \widehat{u}/\|u\|_2 = \widehat{u}/(\sqrt{3}n^{1.5}) = (1/\sqrt{3}, 1/\sqrt{3n}, \cdots, 1/\sqrt{3n})$. Define matrix D to be $A - uu^\top A$. Then, we can compute D,

$$\begin{aligned} D &= A - uu^\top A \\ &= A - \begin{bmatrix} 1/3 & \frac{1}{3\sqrt{n}}\mathbf{1}^\top & \frac{1}{3\sqrt{n}}\mathbf{1}^\top \\ \frac{1}{3\sqrt{n}}\mathbf{1} & \frac{1}{3n}B & \frac{1}{3n}B \\ \frac{1}{3\sqrt{n}}\mathbf{1} & \frac{1}{3n}B & \frac{1}{3n}B \end{bmatrix} A \\ &= \begin{bmatrix} n^{1.5} & 0 & 0 \\ 0 & B & 0 \\ 0 & 0 & B \end{bmatrix} - \begin{bmatrix} \frac{n^{1.5}}{3} & \frac{\sqrt{n}}{3}\mathbf{1}^\top & \frac{\sqrt{n}}{3}\mathbf{1}^\top \\ \frac{n}{3}\mathbf{1} & \frac{1}{3}B & \frac{1}{3}B \\ \frac{n}{3}\mathbf{1} & \frac{1}{3}B & \frac{1}{3}B \end{bmatrix} \\ &= \begin{bmatrix} 2n^{1.5}/3 & -\frac{\sqrt{n}}{3}\mathbf{1}^\top & -\frac{\sqrt{n}}{3}\mathbf{1}^\top \\ -\frac{n}{3}\mathbf{1} & \frac{2}{3}B & -\frac{1}{3}B \\ -\frac{n}{3}\mathbf{1} & -\frac{1}{3}B & \frac{2}{3}B \end{bmatrix}. \end{aligned}$$

Now we need to take the linear combination of columns $D = A - uu^\top A$. Let w denote another sign vector $\{-1, +1\}^{2n+1}$. Then let v denote the basis vector, $v = \sum_{i=1}^{2n+1} D_i$. There are three possibilities, Case I(a), if $w = (1, \{1\}^n, \{1\}^n)$, then v is the all 0 vector. Using vector v to interpolate each column of D, the cost we obtain is at least $2n^2$. Case I(b), if $w = (1, \{1\}^n, \{-1\}^n)$, then $v = (2n^{1.5}/3, \{2/3\}^n, \{-4/3\}^n)$. We also obtain at least $2n^2$ cost if we use that v to interpolate each column of D. Case I(c), if $w = (1, \{-1\}^n, \{-1\}^n)$, then $v = (0, \{-2/3\}^n, \{-2/3\}^n)$. The cost is also at least $2n^2$.

Case II, $s = (1, \{1\}^n, \{-1\}^n)$. Define $\mathbf{1}$ to be a length n all 1s column vector. Define $\widehat{u} = \sum_{i=1}^{2n+1} s_i \cdot A_i = (n^{1.5}, \{n\}^n, \{-n\}^n)$. Let

$$u = \widehat{u}/\|u\|_2 = \widehat{u}/(\sqrt{3}n^{1.5}) = (1/\sqrt{3}, \{1/\sqrt{3n}\}^n, \{-1/\sqrt{3n}\}^n).$$

Define $(2n+1) \times (2n+1)$ matrix D to be $A - uu^\top A$. Then, we can compute D,

$$\begin{aligned}
D &= A - uu^\top A \\
&= A - \begin{bmatrix} 1/3 & \frac{1}{3\sqrt{n}}\mathbf{1}^\top & -\frac{1}{3\sqrt{n}}\mathbf{1}^\top \\ \frac{1}{3\sqrt{n}}\mathbf{1} & \frac{1}{3n}B & -\frac{1}{3n}B \\ -\frac{1}{3\sqrt{n}}\mathbf{1} & -\frac{1}{3n}B & \frac{1}{3n}B \end{bmatrix} A \\
&= \begin{bmatrix} n^{1.5} & 0 & 0 \\ 0 & B & 0 \\ 0 & 0 & B \end{bmatrix} - \begin{bmatrix} n^{1.5}/3 & \frac{\sqrt{n}}{3}\mathbf{1}^\top & -\frac{\sqrt{n}}{3}\mathbf{1}^\top \\ \frac{n}{3}\mathbf{1} & \frac{1}{3}B & -\frac{1}{3}B \\ -\frac{n}{3}\mathbf{1} & -\frac{1}{3}B & \frac{1}{3}B \end{bmatrix} \\
&= \begin{bmatrix} 2n^{1.5}/3 & -\frac{\sqrt{n}}{3}\mathbf{1}^\top & \frac{\sqrt{n}}{3}\mathbf{1}^\top \\ -\frac{n}{3}\mathbf{1} & \frac{2}{3}B & \frac{1}{3}B \\ \frac{n}{3}\mathbf{1} & \frac{1}{3}B & \frac{2}{3}B \end{bmatrix}.
\end{aligned}$$

Similarly to the previous case, we can also discuss three cases.

Case III, $s = (1, \{1\}^n, \{-1\}^n)$. Define $\mathbf{1}$ to be a length n all 1s column vector. Define $\widehat{u} = \sum_{i=1}^{2n+1} s_i \cdot A_i = (n^{1.5}, \{-n\}^n, \{-n\}^n)$. Let $u = \widehat{u}/\|u\|_2 = \widehat{u}/(\sqrt{3}n^{1.5}) = (1/\sqrt{3}, \{-1/\sqrt{3n}\}^n, \{-1/\sqrt{3n}\}^n)$. Define matrix D to be $A - uu^\top A$. Then, we can compute D,

$$
\begin{aligned}
D &= A - uu^\top A \\
&= A - \begin{bmatrix} 1/3 & -\frac{1}{3\sqrt{n}})\mathbf{1}^\top & -\frac{1}{3\sqrt{n}}\mathbf{1}^\top \\ -\frac{1}{3\sqrt{n}}\mathbf{1} & \frac{1}{3n}B & \frac{1}{3n}B \\ -\frac{1}{3\sqrt{n}}\mathbf{1} & \frac{1}{3n}B & \frac{1}{3n}B \end{bmatrix} A \\
&= \begin{bmatrix} n^{1.5} & 0 & 0 \\ 0 & B & 0 \\ 0 & 0 & B \end{bmatrix} - \begin{bmatrix} n^{1.5}/3 & -\frac{\sqrt{n}}{3}\mathbf{1}^\top & -\frac{\sqrt{n}}{3}\mathbf{1}^\top \\ -\frac{n}{3}\mathbf{1} & \frac{1}{3}B & \frac{1}{3}B \\ -\frac{n}{3}\mathbf{1} & \frac{1}{3}B & \frac{1}{3}B \end{bmatrix} \\
&= \begin{bmatrix} 2n^{1.5}/3 & \frac{\sqrt{n}}{3}\mathbf{1}^\top & \frac{\sqrt{n}}{3}\mathbf{1}^\top \\ \frac{n}{3}\mathbf{1} & \frac{2}{3}B & \frac{1}{3}B \\ \frac{n}{3}\mathbf{1} & \frac{1}{3}B & \frac{2}{3}B \end{bmatrix}.
\end{aligned}
$$

Similarly to the previous case, we can also discuss three cases.

17.10.5 Counterexample for [KK05]

We show that there exist matrices such that the algorithm of [KK05] cannot achieve an approximation ratio better than $\Theta(n)$. Their algorithm has two different ways of initialization. We provide counterexamples for each of the initialization separately.

Random vector initialization We provide a counterexample matrix $A \in \mathbb{R}^{n \times n}$ defined as,

$$A = \begin{bmatrix} n^c & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & \cdots & 0 \end{bmatrix} + I, \tag{17.43}$$

where $c \geq 2$. Consider the rank-1 approximation problem for this matrix A. The optimal cost is at most $n - 1$.

Run their algorithm. The starting vectors are $u(0) \sim N(0, I)$ and $v(0) \sim N(0, 1)$. We define two properties for a given vector $y \in \mathbb{R}^n$. Property I is for all $i \in [n]$, $|y_i| \leq n/8$, and Property II is there exist half of the i such that $|y_i| \geq 1/2$. We can show that with probability $1 - 2^{-\Omega(n)}$, both $u(0)$ and $v(0)$ satisfy Property I and II. After 1 iteration, we can show that $u(1)_1 = v(1)_1 = 0$

Now let us use column vector $u(0) \in \mathbb{R}^n$ to interpolate the first column of matrix A. We simplify $u(0)$ to be u. Let u_i denote the i-th coordinate of vector u, $\forall i \in [n]$. Let A_1 denote the first column of matrix A. We define $\alpha = v(1)_1 = \arg\min_\alpha \|\alpha u(0) - A_1\|_1$. For any scalar α, the cost we pay on the first column of matrix A is,

$$|\alpha \cdot u_1 - n^c| + \sum_{i=2}^{n} |\alpha u_i| \geq |\alpha \cdot u_1 - n^c| + \frac{n}{2} |\alpha \cdot \frac{1}{2}| \geq |\alpha \cdot u_1 - n^c| + \frac{n}{4} |\alpha|. \tag{17.44}$$

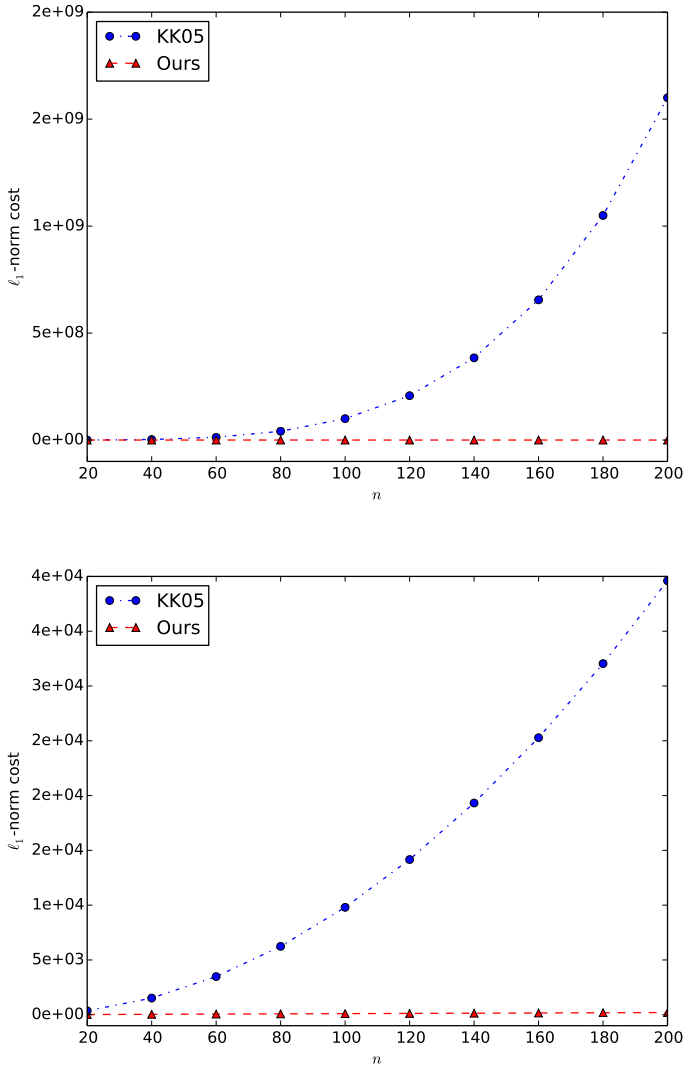

Figure 17.4: The x-axis is n where $A \in \mathbb{R}^{n \times n}$, and the y-axis is $\|A' - A\|_1$ where $\text{rank}(A') = k$. Algorithm [KK05] has two ways of initialization. The left figure shows the performance of both our algorithm and [KK05] with random vector initialization on input matrix A defined as Equation (17.43). The right figure shows the performance of both our algorithm and [KK05] with top singular vector initialization on input matrix A defined as Equation (17.45).

Notice that $c \geq 2$. Then $|\alpha \cdot u_1 - n^c| + \frac{n}{4}|\alpha| \geq |\alpha \cdot \frac{n}{8} - n^c| + \frac{n}{4}|\alpha|$. If $\alpha \leq 0$, then the cost is minimized when $\alpha = 0$. If $\alpha \in [0, 8n^{c-1}]$, the cost is minimized when $\alpha = 0$. If $\alpha \geq 8n^{c-1}$, the cost is minimized when $\alpha = 8n^{c-1}$. Putting it all together, to achieve the minimum cost, there is only one choice for α, which is $\alpha = 0$. The optimal cost is at least n^c.

Then after T iterations(for any $T \geq 1$), $u(T)_1 = v(T)_1 = 0$. Thus, we always pay at least n^c cost on the first entry.

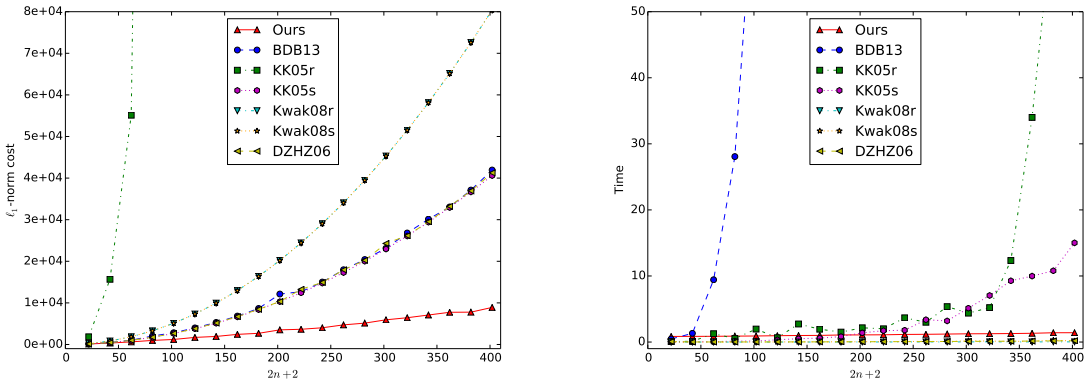
Therefore, their algorithm cannot achieve any approximation ratio better than n^{c-1}. Because $c \geq 2$, we complete the proof.

Top singular vector initialization The counterexample input matrix $A \in \mathbb{R}^{n \times n}$ is defined as,

$$A = \begin{bmatrix} n & 0 \\ 0 & B \end{bmatrix}, \tag{17.45}$$

where matrix $B \in \mathbb{R}^{(n-1)\times(n-1)}$ contains all 1s. Consider the rank-1 approximation problem for this matrix A. The optimal cost is at most n. Run their algorithm. The starting vectors $u(0)$ and $v(0)$ will be set to $(1, 0, \cdots, 0) \in \mathbb{R}^n$. After T iterations(for any $T > 0$), the support of $u(T)$(resp. $v(T)$) is the same as $u(0)$(resp. $v(T)$). Thus, the cost is at least $\|B\|_1 = (n-1)^2$. Therefore, we can conclude that their algorithm cannot achieve any approximation ratio better than $(n-1)^2/n = \Theta(n)$.

17.10.6 Counterexample for all



(a) (b)

Figure 17.5: Let A be $(2n+2) \times (2n+2)$ input matirx. (a) shows the performance of all the algorithms when the matrix dimension is growing. The x-axis is n, and the y-axis is $\|A' - A\|_1$ where A' is the rank-3 solution output by all the heuristic algorithms and also ours. The ℓ_1 residual cost of all the other algorithms is growing much faster than ours, which is consistent with our theoretical results. (b) shows the running time (in seconds) of all the algorithms when the matrix dimension n is growing. The x-axis is n and the y-axis is time (seconds). The running time of some of the algorithms is longer than 3 seconds. For most of the algorithms (including ours), the running time is always less than 3 seconds.

For any $\epsilon \in (0, 0.5)$ and $\gamma > 0$, we construct the input matrix $A \in \mathbb{R}^{(2n+2)\times(2n+2)}$ as follows

$$A = \begin{bmatrix} n^{2+\gamma} & 0 & 0 & 0 \\ 0 & n^{1.5+\epsilon} & 0 & 0 \\ 0 & 0 & B & 0 \\ 0 & 0 & 0 & B \end{bmatrix},$$

where B is $n \times n$ all 1s matrix. We want to find a rank $k = 3$ solution for A. Then any of those four heuristic algorithms [KK05, DZHZ06, Kwa08, BDB13] is not able to achieve better than $n^{\min(\gamma, 0.5-\epsilon)}$ approximation ratio. We present our main experimental results in Figure 17.5.

Both [KK05] and [Kwa08] have two different ways of initialization. In Figure 17.5 we use KK05r(resp. Kwak08r) to denote the way that uses random vector as initialization, and use KK05s(resp. Kwak08s) to denote the way that uses top singular vector as initialization. Figure 17.5(a) shows the performance of all the algorithms and Figure 17.5(b) presents the running time. The ℓ_1 residual cost of all the other algorithm is growing much faster than our algorithm. Most of the algorithms (including ours) are pretty efficient, i.e., the running time is always below 3 seconds. The running time of [BDB13, KK05] is increasing very fast when the matrix dimension n is growing.

In Figure 17.5(a), the cost of KK05r at $\{82, \cdots, 142\}$ is in $[10^5, 10^6]$, at $\{162, \cdots, 302\}$ is in $[10^6, 10^7]$, and at $\{322, \cdots, 402\}$ is in $[10^7, 10^8]$. In Figure 17.5(b), the time of KK05r at $\{382, 482\}$ is 64s and 160s. The running time of BDB13 at $\{82, \cdots, 222\}$ is between 1 minute and 1 hour. The running time of BDB13 at $\{242, \cdots, 322\}$ is between 1 hour and 20 hours. The running time of BDB13 at $\{342, \cdots, 402\}$ is more than 20 hours.

17.10.7 Discussion for Robust PCA [CLMW11]

A popular method is robust PCA [CLMW11], which given a matrix A, tries to find a matrix L for which $\lambda\|A-L\|_1+\|L\|_*$ is minimized, where $\lambda>0$ is a tuning parameter and $\|L\|_*$ is the nuclear norm of L. This is a convex program, but it need not return a low rank matrix L with relative error. As a simple example, suppose $\lambda=1$, and the $n\times n$ matrix A is a block-diagonal matrix of rank k and $n=\frac{k}{2}(b+1)$. Further, the first $k/2$ blocks are $b\times b$ matrices of all 1s, while the next $k/2$ blocks are just a single value b on the diagonal.

Then the solution to the above problem may return L to be the first $k/2$ blocks of A. The total cost of $\lambda\|A-L\|_1+\|L\|_*$is $(k/2)b+(k/2)b=kb$.

Also, the solution to the above problem may return L to be A, which has cost $0+\|A\|_*=kb$. Because this solution has the same cost, it means that their algorithm might output a rank-k solution, and also might output a rank-$k/2$ solution.

Therefore, the relative error of the output matrix may be arbitrarily bad for ℓ_1-low rank approximation.

We also consider the following example. Suppose $\lambda=1/\sqrt{n}$, and let $n\times n$ matrix A denote the Hadamard matrix H_n. Recall that the Hadamard matrix H_p of size $p\times p$ is defined recursively : $\begin{bmatrix}H_{p/2} & H_{p/2}\\ H_{p/2} & -H_{p/2}\end{bmatrix}$ with $H_2=\begin{bmatrix}+1 & +1\\ +1 & -1\end{bmatrix}$. Notice that every singular values of A is $\sqrt{n}$. We consider the objective function $\lambda\|A-L\|_1+\|L\|_*$.

Then the solution to the above problem may return L to be the first $n/2$ rows of A. The total cost of $\lambda\|A-L\|_1+\|L\|_*$ is $(1/\sqrt{n})n^2/2+(n/2)\sqrt{n}=n^{1.5}$. Also, the solution to the above problem may return L to be A, which has cost $0+\|A\|_*=n\sqrt{n}=n^{1.5}$. For any i, if the solution takes i rows of A, the cost is $(1/\sqrt{n})(n-i)n+i\sqrt{n}=n^{1.5}$. Because this

solution has the same cost, it means that their algorithm might output a rank-n solution, and also might output a rank-$n/2$ solution. Therefore, the relative error of the output matrix may be arbitrarily bad for ℓ_1-low rank approximation.

17.11 Limited Independent Cauchy Random Variables

This section presents the fundamental lemmas with limited independent Cauchy variables, which will be used in Section 17.12 and 17.13. In Section 17.11.1, we provide some notation, definitions and tools from previous work. Section 17.11.2 includes the main result.

17.11.1 Notations and tools

For a function $f : \mathbb{R} \to \mathbb{R}$ and nonnegative integer ℓ, $f^{(\ell)}$ denotes the ℓth derivative of f, with $f^{(0)} = f$. We also often use $x \approx_\epsilon y$ to state that $|x - y| = O(\epsilon)$. We use $I_{[a,b]}$ to denote the indicator function of the interval $[a, b]$.

To optimize the communication complexity of our distributed algorithm, we show that instead of using fully independent Cauchy variables, poly(k, d)-wise independent Cauchy variables suffice.

We start by stating two useful Lemmas from previous work [KNW10a].

Lemma 17.11.1 (Lemma 2.2 in [KNW10a])**.** *There exists an $\epsilon_0 > 0$ such that the following holds. Let n be a positive integer and $0 < \epsilon < \epsilon_0$, $0 < p < 2$ be given. Let $f : \mathbb{R} \to \mathbb{R}$ satisfy $\|f^{(\ell)}\|_\infty = O(\alpha^\ell)$ for all $\ell \geq 0$, for some α satisfying $\alpha^p \geq \log(1/\epsilon)$. Let $k = \alpha^p$. Let $a \in \mathbb{R}^n$ satisfy $\|a\|_p = O(1)$. Let X_i be a $3Ck$-independent family of p-stable random variables. Let $X = \sum_i a_i X_i$ and $Y = \sum_i a_i Y_i$. Then $\mathbb{E}[f(x)] = \mathbb{E}[f(Y)] + O(\epsilon)$.*

Lemma 17.11.2 (Lemma 2.5 in [KNW10a])**.** *There exist constants $c', \epsilon_0 > 0$ such that for all $c > 0$ and $0 < \epsilon < \epsilon_0$, and for all $[a, b] \subseteq \mathbb{R}$, there exists a function $J^c_{[a,b]} : \mathbb{R} \to \mathbb{R}$ satisfying:*

i. $\|(J^c_{[a,b]})^{(\ell)}\|_\infty = O(c^\ell)$ for all $\ell \geq 0$.

ii. For all x such that $a, b \notin [x - \epsilon, x + \epsilon]$, and as long as $c > c'\epsilon^{-1} \log^3(1/\epsilon)$, $|J^c_{[a,b]}(x) - I_{[a,b]}(x)| < \epsilon$.

17.11.2 Analysis of limited independent random Cauchy variables

Lemma 17.11.3. *Given a vector $y \in \mathbb{R}^n$, choose Z to be the $t \times n$ random Cauchy matrices with $1/t$ rescaling and $t = O(k \log k)$. The variables from different rows are fully independent, and the variables from the same rows are $O(1)$-wise independent. Then, we have*

$$\|Zy\|_1 \gtrsim \|y\|_1$$

holds with probability at least $1 - 2^{-\Omega(t)}$.

Proof. Let S denote the original fully independent matrix and Z denote the matrix for which the entries in the same row are w-wise independent, and the entries from different rows are fully independent. Notice we define the random matrices without rescaling by $1/t$ and it will be added back at the end. (We will decide w later)

We define random variable X such that $X = 1$ if $|(Zy)_i| \leq \frac{1}{50}$ and $X = 0$ otherwise. We also define random variable Y such that $Y = 1$ if $|(Sy)_i| \leq \frac{1}{50}$ and $Y = 0$ otherwise. Then, we have

$$\mathbb{E}[X] = \Pr\left[|(Zy)_i| \leq \frac{1}{50}\right] = \mathbb{E}\left[I_{[-\frac{1}{50},\frac{1}{50}]}((Zy)_i)\right]$$
$$\mathbb{E}[Y] = \Pr\left[|(Sy)_i| \leq \frac{1}{50}\right] = \mathbb{E}\left[I_{[-\frac{1}{50},\frac{1}{50}]}((Sy)_i)\right]$$

The goal is to show that $\mathbb{E}[X] \approx_\epsilon \mathbb{E}[Y]$. Following the same idea from [KNW10a], we need to argue this chain of inequalities,

$$\mathbb{E}[I_{[a,b]}(X)] \approx_\epsilon \mathbb{E}[J^c_{[a,b]}(X)] \approx_\epsilon \mathbb{E}[J^c_{[a,b]}(Y)] \approx_\epsilon \mathbb{E}[I_{[a,b]}(Y)]$$

Using Lemma 2.2 and Lemma 2.5 from [KNW10a], choosing sufficiently small constant ϵ(which implies $w = O(1)$), it follows that for each $i \in [t]$, we still have

$$\Pr\left[|(Zy)_i| > \frac{1}{50}\|y\|_1\right] \gtrsim \Pr\left[|(Sy)_i| > \frac{1}{50}\|y\|_1\right] \geq 0.9$$

Because all rows of Z are fully independent, using the Chernoff bound we can get that

$$\Pr\left[\|Zy\|_1 \lesssim t\|y\|_1\right] \leq \exp(-\Omega(t))$$

as we needed for the "no contraction" part of the net argument. □

For the no dilation, we need to argue that

Lemma 17.11.4. *Given a set of vectors $\{y_1, y_2, \ldots, y_d\}$ where $y_i \in \mathbb{R}^n, \forall i \in [d]$, choose Z to be the $t \times n$ random Cauchy matrices with $1/t$ rescaling and $t = O(k \log k)$, where the variables from different rows are fully independent, and the variables from the same rows are w-wise independent.*

I. *If $w = \widetilde{O}(dk)$, we have*

$$\sum_{i=1}^{d} \|Zy_i\|_1 \leq O(\log d) \sum_{i=1}^{d} \|y_i\|_1$$

holds with probability at least .999.

II. *If If $w = \widetilde{O}(d)$, we have*

$$\sum_{i=1}^{d} \|Zy_i\|_1 \leq O(k \log d) \sum_{i=1}^{d} \|y_i\|_1$$

holds with probability at least .999.

Proof. Let $m = t$. Let $S \in \mathbb{R}^{m \times n}$ denote the original fully independent matrix and Z denote the matrix that for each entry in the same row are w-wise independent, where the entries from different rows are fully independent. (We will decide on$w$ later)

Applying matrix S to those fixed set of vectors, we have

$$\sum_{i=1}^{d} \|Sy_i\|_1 = \sum_{i=1}^{d} \sum_{j=1}^{m} |\sum_{l=1}^{n} \frac{1}{m} S_{j,l} \cdot (y_i)_l| = \frac{1}{m} \sum_{i=1}^{d} \sum_{j=1}^{m} |\sum_{l=1}^{n} S_{j,l} \cdot (y_i)_l|$$

Applying matrix Z to those fixed set of vectors, we have a similar thing,

$$\sum_{i=1}^{d} \|Zy_i\|_1 = \sum_{i=1}^{d} \sum_{j=1}^{m} |\sum_{l=1}^{n} \frac{1}{m} Z_{j,l} \cdot (y_i)_l| = \frac{1}{m} \sum_{i=1}^{d} \sum_{j=1}^{m} |\sum_{l=1}^{n} Z_{j,l} \cdot (y_i)_l|$$

The goal is to argue that, for any $i \in [d], j \in [m]$,

$$\mathbb{E}\Big[|\sum_{l=1}^{n} Z_{j,l} \cdot (y_i)_l| \Big| \xi \Big] \lesssim \mathbb{E}\Big[|\sum_{l=1}^{n} S_{j,l} \cdot (y_i)_l| \Big| \xi \Big] + \delta$$

As long as δ is small enough, we are in a good shape.

Let $X = \frac{1}{\|y_i\|_1} \sum_{l=1}^{n} Z_{j,l}(y_i)_l$, and $Y = \frac{1}{\|y_i\|_1} \sum_{l=1}^{m} S_{j,l}(y_i)_l$. Let D be the truncating threshold of each Cauchy random variable. Define $T = O(\log D)$. On one hand, we have

$$\begin{aligned}
\mathbb{E}[|X||\xi] &\leq 2 \left(\Pr[X \in [0,1]|\xi] \cdot 1 + \sum_{j=0}^{T} \Pr[X \in (2^j, 2^{j+1}]|\xi] \cdot 2^{j+1} \right) \\
&\leq 2 \left(1 + \sum_{j=0}^{T} \Pr[I_{(2^j, 2^{j+1})}(X) = 1|\xi] \cdot 2^{j+1} \right) \\
&= 2 \left(1 + \sum_{j=0}^{T} \mathbb{E}[I_{(2^j, 2^{j+1})}(X)|\xi] \cdot 2^{j+1} \right) \qquad (17.46)
\end{aligned}$$

On the other hand, we can show

$$\begin{aligned}\mathbb{E}[|Y||\xi] &\geq 2\left(\Pr[X \in [0,1]|\xi] \cdot 0 + \sum_{j=0}^{T} \Pr[Y \in (2^j, 2^{j+1}]|\xi] \cdot 2^j\right) \\ &\geq 2\sum_{j=0}^{T} \Pr[I_{(2^j,2^{j+1}]}(Y) = 1|\xi] \cdot 2^j \\ &\geq 2\sum_{j=0}^{T} \mathbb{E}[I_{(2^j,2^{j+1}]}(Y)|\xi] \cdot 2^j \end{aligned} \tag{17.47}$$

Thus, we need to show that, for each j,

$$\mathbb{E}[I_{(2^j,2^{j+1})}(X)|\xi] \approx_\epsilon \mathbb{E}[I_{(2^j,2^{j+1}]}(Y)|\xi] \tag{17.48}$$

Following the same idea from [KNW10a], we need to argue this chain of inequalities,

$$\mathbb{E}[I_{[a,b]}(X)] \approx_\epsilon \mathbb{E}[J^c_{[a,b]}(X)] \approx_\epsilon \mathbb{E}[J^c_{[a,b]}(Y)] \approx_\epsilon \mathbb{E}[I_{[a,b]}(Y)]$$

We first show $\mathbb{E}[I_{[a,b]}(X)] \approx_\epsilon \mathbb{E}[J^c_{[a,b]}(X)]$. Notice that $I_{[a,b]}$ and $J_{[a,b]}$ are within ϵ everywhere except for two intervals of length $O(\epsilon)$. Also the Cauchy distribution is anticoncentrated (any length-$O(\epsilon)$ interval contains $O(\epsilon)$ probability mass) and $\|I_{[a,b]}\|_\infty, \|J^c_{[a,b]}\|_\infty = O(1)$, these intervals contribute $O(\epsilon)$ to the difference.

Second, we show $\mathbb{E}[J^c_{[a,b]}(X)] \approx_\epsilon \mathbb{E}[J^c_{[a,b]}(Y)]$. This directly follows by Lemma 17.11.1 by choosing $\alpha = O(\epsilon^{-1}\log^3(1/\epsilon))$.

Third, we show $\mathbb{E}[J^c_{[a,b]}(Y)] \approx_\epsilon \mathbb{E}[I_{[a,b]}(Y)]$. The argument is similar as the first step, but we need to show anticoncentration of Y. Suppose for any $t \in \mathbb{R}$ we had a nonnegative

function $f_{\epsilon,t} : \mathbb{R} \to \mathbb{R}$ symmetric about t satisfying:

I. $\|f_{t,\epsilon}^{(\ell)}\|_\infty = O(\alpha^\ell)$ for all $\ell \geq 0$, with $\alpha = O(1/\epsilon)$

II. $\mathbb{E}[f_{t,\epsilon}(z)] = O(\epsilon)$ for $z \sim \mathcal{D}_1$

III. $f_{t,\epsilon}(t+\epsilon) = \Omega(1)$

IV. $f_{t,\epsilon}(x)$ is strictly decreasing as $|x-t| \to \infty$

By I, II and Lemma 17.11.1 we could have $\mathbb{E}[f_{\epsilon,t}(Y)] \approx_\epsilon \mathbb{E}[f_{t,\epsilon}(z)] = O(\epsilon)$. Then, $\mathbb{E}[f_{t,\epsilon}(Y)] \geq f_{t,\epsilon}(t+\epsilon) \cdot \Pr[Y \in [t-\epsilon, t+\epsilon]] = \Omega(\Pr[Y \in [t-\epsilon, t+\epsilon]])$ by III and IV, implying anticoncentration in $[t-\epsilon, t+\epsilon]$ as desired. For the details of function $f_{t,\epsilon}$, we refer the readers to Section A.4 in [KNW10a].

Now, combining Equation (17.46), (17.47) and (17.48) gives

$$\begin{aligned}\mathbb{E}\left[|\sum_{l=1}^{n} Z_{j,l} \cdot (y_i)_l| \middle| \xi\right] &\lesssim \mathbb{E}\left[|\sum_{l=1}^{n} S_{j,l} \cdot (y_i)_l| \middle| \xi\right] + \sum_{j=0}^{T} 2^j \cdot \epsilon \cdot \|y_i\|_1 \\ &\lesssim \mathbb{E}\left[|\sum_{l=1}^{n} S_{j,l} \cdot (y_i)_l| \middle| \xi\right] + D \cdot \epsilon \cdot \|y_i\|_1\end{aligned}$$

Overall, for the fixed j, $S_{j,l}$ is $\widetilde{O}(1/\epsilon)$-independent family of Cauchy random variable. Choosing $D = O(dk)$ and $\epsilon = O(1/D)$, we can show

$$\frac{1}{m}\sum_{i=1}^{d}\sum_{j=1}^{m}\mathbb{E}\left[|\sum_{l=1}^{n} S_{j,l} \cdot (y_i)_l| \middle| \xi\right] \leq O(\log d)\sum_{i=1}^{d}\|y_i\|_1$$

as before. Notice that $D\epsilon\|y_i\|_1 = O(\|y_i\|_1)$. Thus, we complete the proof of the first result.

Choosing $D = O(dk)$ and $\epsilon = O(1/d)$, the dominant term becomes $D\epsilon\|y_i\|_1 = O(k\|y_i\|_1)$. Thus, we complete the proof of second result. □

Corollary 17.11.5. *Given $U \in \mathbb{R}^{n\times k}$, let $Z \in \mathbb{R}^{t\times n}$ be the same as the matrix stated in the Lemma 17.11.3, then with probability at least .95,*

$$\forall x \in \mathbb{R}^k, \|ZUx\|_1 \gtrsim \|Ux\|_1.$$

The proof is very similar to the proof of Lemma 17.5.14. Without loss of generality, we can suppose U is a well-conditioned basis. Due to Lemma 17.11.4, with arbitrarily high constant probability $\|ZU\|_1$ is bounded by $\text{poly}(t, k)$. By simply applying the net argument and using Lemma 17.11.3 to take a union bound over net points, we can get the above corollary.

17.12 Streaming Setting

Section 17.12.1 provides some notation and definitions about row-update streaming model and the turnstile streaming model. For some recent developments of row-update streaming and turnstile streaming models, we refer the readers to [CW09, KL11, GP14, Lib13, KLM+14a, BWZ16] and the references therein. Section 17.12.2 presents our turnstile streaming algorithm. Section 17.12.3 presents our row-update streaming algorithm.

17.12.1 Definitions

Definition 17.12.1 (Row-update model)**.** Let matrix $A \in \mathbb{R}^{n \times d}$ be a set of rows $A_1, \cdots, A_n$. In the row-update streaming model, each row of A will occur in the stream exactly once. But the rows can be in arbitrary order. An algorithm in this model is only allowed a single pass over these rows. At the end of the stream, the algorithm stores some information of A. The space of the algorithm is the total number of words required to store this information during the stream. Here, each word is $O(\log(nd))$ bits.

Definition 17.12.2 (Turnstile model)**.** At the beginning, let matrix $A \in \mathbb{R}^{n \times d}$ be a zero matrix. In the turnstile streaming model, there is a stream of update operations, and the i^{th} operation has the form (x_i, y_i, c_i) which means that A_{x_i, y_i} should be incremented by c_i. An algorithm in this model is only allowed a single pass over the stream. At the end of the stream, the algorithm stores some information of A. The space complexity of the algorithm is the total number of words required to store this information during the stream. Here, each word is $O(\log(nd))$ bits.

17.12.2 Turnstile model, $\mathrm{poly}(k, \log(d), \log(n))$ approximation

Definition 17.12.3 (Turnstile model ℓ_1-low rank approximation - rank-k subspace version)**.** Given matrix $A \in \mathbb{R}^{n \times d}$ and $k \in \mathbb{N}_+$, the goal is to propose an algorithm in the streaming model of Definition 17.12.2 such that

1. Upon termination, the algorithm outputs a matrix $V^* \in \mathbb{R}^{k \times d}$.
2. V^* satisfies that

$$\min_{U \in \mathbb{R}^{n \times k}} \|A - UV^*\|_1 \leq \mathrm{poly}(k, \log(d), \log(n)) \cdot \min_{U \in \mathbb{R}^{n \times k}, V \in \mathbb{R}^{k \times d}} \|A - UV\|_1.$$

3. The space complexity is as small as possible

Theorem 17.12.1. *Suppose $A \in \mathbb{R}^{n \times d}$ is given in the turnstile streaming model (See Definition 17.12.2), there is an algorithm(in Algorithm 17.8 without decomposition) which solves the problem in Definition 17.12.3 with constant probability. Further, the space complexity of the algorithm is $\mathrm{poly}(k) + \widetilde{O}(kd)$ words.*

Proof. **Correctness.** The correctness is implied by (IV) of Lemma 17.5.5, and the proof of Theorem 17.4.3. Notice that $L = T_1 AR, N = SAT_2, M = T_1 AT_2$, so $\widehat{X} \in \mathbb{R}^{O(k \log k) \times O(k \log k)}$ minimizes

$$\min_{\mathrm{rank}-k \ X} \|T_1 ARXSAT_2 - T_1 AT_2\|_F.$$

According to the proof of Theorem 17.4.3, $AR\widehat{X}SA$ gives a ℓ_1 rank-k $\mathrm{poly}(k, \log(d), \log(n))$-approximation to A. Because $\widehat{X} = \widehat{U}\widehat{\Sigma}\widehat{V}^\top$, $V^* = \widehat{\Sigma}\widehat{V}^\top SA$ satisfies:

$$\min_{U \in \mathbb{R}^{n \times k}} \|A - UV^*\|_1 \leq \mathrm{poly}(k, \log(d), \log(n)) \cdot \min_{U \in \mathbb{R}^{n \times k}, V \in \mathbb{R}^{k \times d}} \|A - UV\|_1.$$

Space complexity. Generating $\widetilde{O}(kd)$-wise independent random Cauchy variables needs $\widetilde{O}(kd)$ bits. The size of L, N and M are $k^2 \log^2 k, k^2 \log^3 k$ and $k^2 \log^3 k$ words separately. So the space of maintaining them is $O(k^2 \log^3 k)$ words. The size of D is $O(k \log k) \times d$, so maintaining it needs $O(kd \log k)$ words. Therefore, the total space complexity of the algorithm is $\mathrm{poly}(k) + \widetilde{O}(kd)$ words.

□

It is easy to extend our algorithm to output a decomposition. The formal definition of the decomposition problem is as the following:

Definition 17.12.4 (Turnstile model ℓ_1-low rank approximation - rank-k decomposition version)**.** Given matrix $A \in \mathbb{R}^{n \times d}$ and $k \in \mathbb{N}_+$, the goal is to propose an algorithm in the streaming model of Definition 17.12.2 such that

1. Upon termination, the algorithm outputs a matrix $U^* \in \mathbb{R}^{n \times k}, V^* \in \mathbb{R}^{k \times d}$.
2. U^*, V^* satisfies
$$\|A - U^* V^*\|_1 \leq \mathrm{poly}(k, \log(d), \log(n)) \cdot \min_{U \in \mathbb{R}^{n \times k}, V \in \mathbb{R}^{k \times d}} \|A - UV\|_1.$$
3. The space complexity is as small as possible

Theorem 17.12.2. *Suppose $A \in \mathbb{R}^{n \times d}$ is given by the turnstile streaming model (See Definition 17.12.2). There is an algorithm(in Algorithm 17.8 with decomposition) which solves the problem in Definition 17.12.4 with constant probability. Further, the space complexity of the algorithm is* $\mathrm{poly}(k) + \widetilde{O}(k(d+n))$ *words.*

Proof. **Correctness.** The only difference from the Algorithm 17.8 (without decomposition) is that the algorithm maintains C. Thus, finally it can compute $U^* = AR\widehat{U}$. Notice that $U^*V^* = AR\widehat{X}SA$, according to the proof of Theorem 17.4.3, U^*V^* gives a ℓ_1 rank-k $\mathrm{poly}(k, \log(d), \log(n))$-approximation to A.

Space complexity. Since the size of C is $O(nk \log k)$ words, the total space is $\mathrm{poly}(k) + \widetilde{O}(k(d+n))$ words.

□

17.12.3 Row-update model, $\mathrm{poly}(k)\log d$ approximation

Definition 17.12.5 (Row-update model ℓ_1-low rank approximation - rank-k subspace version)**.** Given matrix $A \in \mathbb{R}^{n\times d}$ and $k \in \mathbb{N}_+$, the goal is to propose an algorithm in the streaming model of Definition 17.12.1 such that

1. Upon termination, the algorithm outputs a matrix $V^* \in \mathbb{R}^{k\times d}$.
2. V^* satisfies that

$$\min_{U\in\mathbb{R}^{n\times k}} \|A - UV^*\|_1 \leq \mathrm{poly}(k)\log(d) \cdot \min_{U\in\mathbb{R}^{n\times k}, V\in\mathbb{R}^{k\times d}} \|A - UV\|_1.$$

3. The space complexity is as small as possible

Theorem 17.12.3. *Suppose $A \in \mathbb{R}^{n\times d}$ is given by the row-update streaming model (See Definition 17.12.1), there is an algorithm(in Algorithm 17.9 without decomposition) which solves the problem in Definition 17.12.5 with constant probability. Further, the space complexity of the algorithm is $\mathrm{poly}(k) + \widetilde{O}(kd)$ words.*

Proof. **Correctness.** Notice that $L = T_1BR, N = SBT_2, M = T_1BT_2$. Thus, $\widehat{X} \in \mathbb{R}^{O(k\log k)\times O(k\log k)}$ actually minimizes

$$\min_{\mathrm{rank}-k\ X} \|T_1BRXSBT_2 - T_1BT_2\|_F.$$

Also notice that B is just taking each row of A and replacing it with its nearest point in the row span of $S'A$. According to the proof of Theorem 17.4.6 and (IV) of Lemma 17.5.5 $BR\widehat{X}SB$ gives a $\mathrm{poly}(k)\log d$ ℓ_1 norm rank-k approximation to A. Since $\widehat{X} = \widehat{U}\widehat{\Sigma}\widehat{V}^\top$, $V^* = \widehat{\Sigma}\widehat{V}^\top SB$ satisfies:

$$\min_{U\in\mathbb{R}^{n\times k}} \|A - UV^*\|_1 \leq \mathrm{poly}(k, \log(d), \log(n)) \cdot \min_{U\in\mathbb{R}^{n\times k}, V\in\mathbb{R}^{k\times d}} \|A - UV\|_1.$$

Space complexity. Constructing sketching matrices needs $\widetilde{O}(kd)$ bits to store random seeds. Maintaining L, N, M needs $O(k^2 \log^3 k)$ words. The cost of storing $\widehat{X}$ is also $O(k^2 \log^2 k)$ words. Maintaining D needs $O(kd \log k)$ words. Therefore, the total space cost of the algorithm is $\mathrm{poly}(k) + \widetilde{O}(kd)$ words. □

It is easy to extend our algorithm to output a decomposition. The formal definition of the decomposition problem is as the following:

Definition 17.12.6 (Row-update model ℓ_1-low rank approximation - rank-k decomposition version)**.** Given matrix $A \in \mathbb{R}^{n \times d}$ and $k \in \mathbb{N}_+$, the goal is to propose an algorithm in the streaming model of Definition 17.12.1 such that

1. Upon termination, the algorithm outputs matrices $U^* \in \mathbb{R}^{n \times k}, V^* \in \mathbb{R}^{k \times d}$.
2. U^*, V^* satisfies that
$$\|A - U^* V^*\|_1 \leq \mathrm{poly}(k) \log d \cdot \min_{U \in \mathbb{R}^{n \times k}, V \in \mathbb{R}^{k \times d}} \|A - UV\|_1.$$
3. The space complexity is as small as possible.

Theorem 17.12.4. *Suppose $A \in \mathbb{R}^{n \times d}$ is given by the row-update streaming model (See Definition 17.12.1), there is an algorithm(in Algorithm 17.9 with decomposition) which solves the problem in Definition 17.12.6 with constant probability. Further, the space complexity of the algorithm is* $\mathrm{poly}(k) + \widetilde{O}(k(n+d))$ *words.*

Proof. **Correctness.** The only difference is that the above algorithm maintains C. Thus, We can compute $U^* = C\widehat{U}$ in the end. Notice that $U^* V^* = BR\widehat{X}SB$, according to the proof of Theorem 17.4.6, $U^* V^*$ gives a $\mathrm{poly}(k) \log d$ ℓ_1 norm rank-k approximation to A.

Space complexity. Since the size of C is $nk \log k$ words, the total space is $\mathrm{poly}(k) + \widetilde{O}(k(n+d))$ words. $\square$

17.13 Distributed Setting

Section 17.13.1 provides some notation and definitions for the Row-partition distributed model and the Arbitrary-partition model. These two models were recently studied in a line of works such as [TD99, QOSG02, BCL05, BRB08, MBZ10, FEGK13, PMvdG+13, KVW14, BKLW14, BLS+16b, BWZ16, WZ16]. Section 17.13.2 and 17.13.3 presents our distributed protocols for the Arbitrary-partition distributed model. Section 17.13.4 and 17.13.5 presents our distributed protocols for the Row-partition distributed model.

17.13.1 Definitions

Definition 17.13.1 (Row-partition model [BWZ16])**.** There are s machines, and the i^{th} machine has a matrix $A_i \in \mathbb{R}^{n_i \times d}$ as input. Suppose $n = \sum_{i=1}^{s} n_i$, and the global data matrix $A \in \mathbb{R}^{n \times d}$ is denoted as

$$\begin{pmatrix} A_1 \\ A_2 \\ \cdots \\ A_s \end{pmatrix},$$

we say A is row-partitioned into these s matrices distributed in s machines respectively. Furthermore, there is a machine which is a coordinator. The model only allows communication between the machines and the coordinator. The communication cost in this model is the total number of words transferred between machines and the coordinator. Each word is $O(\log(snd))$ bits.

Definition 17.13.2 (Arbitrary-partition model [BWZ16])**.** There are s machines, and the i^{th} machine has a matrix $A_i \in \mathbb{R}^{n \times d}$ as input. Suppose the global data matrix $A \in \mathbb{R}^{n \times d}$ is denoted as $A = \sum_{i=1}^{s} A_i$. We say A is arbitrarily partitioned into these s matrices distributed in s machines respectively. Furthermore, there is a machine which is a coordinator. The model only allows communication between the machines and the coordinator. The communication cost in this model is the total number of words transferred between machines and the coordinator. Each word is $O(\log(snd))$ bits.

17.13.2 Arbitrary-partition model, subspace, $\mathrm{poly}(k, \log(d), \log(n))$ approximation

Definition 17.13.3 (Arbitrary-partition model ℓ_1-low rank approximation - rank-k subspace version)**.** Given matrix $A \in \mathbb{R}^{n \times d}$ arbitrarily partitioned into s matrices $A_1, A_2, \cdots, A_s$ distributed in s machines respectively, and $k \in \mathbb{N}_+$, the goal is to propose a protocol in the model of Definition 17.13.2 such that

1. Upon termination, the protocol leaves a matrix $V^* \in \mathbb{R}^{k \times d}$ on the coordinator.
2. V^* satisfies that

$$\min_{U \in \mathbb{R}^{n \times k}} \|A - UV^*\|_1 \leq \mathrm{poly}(k, \log(d), \log(n)) \cdot \min_{U \in \mathbb{R}^{n \times k}, V \in \mathbb{R}^{k \times d}} \|A - UV\|_1.$$

3. The communication cost is as small as possible

Theorem 17.13.1. *Suppose $A \in \mathbb{R}^{n \times d}$ is partitioned in the arbitrary partition model (See Definition 17.13.2). There is a protocol(in Algorithm 17.10) which solves the problem in Definition 17.13.3 with constant probability. Further, the communication complexity of the protocol is $s(\mathrm{poly}(k) + \widetilde{O}(kd))$ words.*

Proof. **Correctness.** The correctness is shown by the proof of Theorem 17.4.3 and (IV) of Lemma 17.5.5. Notice that $\widehat{X} \in \mathbb{R}^{O(k \log k) \times O(k \log k)}$ minimizes

$$\min_{\mathrm{rank}-k \ X} \|LXN - M\|_F.$$

which is

$$\min_{\mathrm{rank}-k \ X} \|T_1 ARXSAT_2 - T_1 AT_2\|_F.$$

According to the proof of Theorem 17.4.3, $AR\widehat{X}SA$ gives an ℓ_1 rank-k $\mathrm{poly}(k, \log(d), \log(n))$-approximation to A. Because $\widehat{X} = \widehat{U}\widehat{\Sigma}\widehat{V}^\top$, $V^* = \widehat{\Sigma}\widehat{V}^\top SA$ satisfies:

$$\min_{U \in \mathbb{R}^{n \times k}} \|A - UV^*\|_1 \leq \mathrm{poly}(k, \log(d), \log(n)) \cdot \min_{U \in \mathbb{R}^{n \times k}, V \in \mathbb{R}^{k \times d}} \|A - UV\|_1.$$

Communication complexity. Since the random seed generates $\widetilde{O}(kd)$-wise independent random Cauchy variables, the cost of line 5 is $\widetilde{O}(skd)$ bits. The size of L_i, N_i and M_i are $k^2 \log^2 k, k^2 \log^3 k$ and $k^2 \log^3 k$ words separately. So the cost of line 15 is $O(sk^2 \log^3 k)$ words. Because the size of $\widehat{X}$ is $O(k^2 \log^2 k)$, the cost of line 22 is $O(sk^2 \log^2 k)$ words. line 30 needs skd words of communication. Therefore, the total communication of the protocol is $s(\mathrm{poly}(k) + \widetilde{O}(kd))$ words.

□

17.13.3 Arbitrary-partition model, decomposition, $\mathrm{poly}(k, \log(d), \log(n))$ approximation

Definition 17.13.4 (Arbitrary-partition model ℓ_1-low rank approximation - rank-k decomposition version)**.** Given matrix $A \in \mathbb{R}^{n \times d}$ arbitrarily partitioned into s matrices $A_1, A_2, \cdots, A_s$ distributed in s machines respectively, and $k \in \mathbb{N}_+$, the goal is to propose a protocol in the model of Definition 17.13.2 such that

1. Upon termination, the protocol leave matrices $U^* \in \mathbb{R}^{n \times k}, V^* \in \mathbb{R}^{k \times d}$ on the coordinator.

2. U^*, V^* satisfies that

$$\|A - U^* V^*\|_1 \leq \mathrm{poly}(k, \log(d), \log(n)) \cdot \min_{U \in \mathbb{R}^{n \times k}, V \in \mathbb{R}^{k \times d}} \|A - UV\|_1.$$

3. The communication cost is as small as possible.

Theorem 17.13.2. *Suppose $A \in \mathbb{R}^{n \times d}$ is partitioned in the arbitrary partition model (See Definition 17.13.2). There is a protocol(in Algorithm 17.10 with decomposition) which solves the problem in Definition 17.13.4 with constant probability. Further, the communication complexity of the protocol is $s(\mathrm{poly}(k) + \widetilde{O}(k(d+n)))$ words.*

Proof. **Correctness.** The only difference from the protocol (without decomposition) in Section 17.13.2 is that the protocol sends U_i. Thus, the coordinator can compute $U^* = AR\widehat{U}$. Notice that $U^* V^* = AR\widehat{X}SA$. According to the proof of Theorem 17.4.3, $U^* V^*$ gives a ℓ_1 rank-k $\mathrm{poly}(k, \log(d), \log(n))$-approximation to A.

Communication complexity. Since the size of U_i is kn words, the total communication is $s(\mathrm{poly}(k) + \widetilde{O}(k(d+n)))$ words.

□

17.13.4 Row-partition model, subspace, $\mathrm{poly}(k)\log d$ approximation

Definition 17.13.5 (Row-partition model ℓ_1-low rank approximation - rank-k subspace version)**.** Given matrix $A \in \mathbb{R}^{n\times d}$ row-partitioned into s matrices $A_1, A_2, \cdots, A_s$ distributed in s machines respectively, and $k \in \mathbb{N}_+$, the goal is to propose a protocol in the model of Definition 17.13.1 such that

1. Upon termination, the protocol leaves a matrix $V^* \in \mathbb{R}^{k\times d}$ on the coordinator.
2. V^* satisfies that
$$\min_{U\in\mathbb{R}^{n\times k}} \|A - UV^*\|_1 \leq \mathrm{poly}(k)\log d \cdot \min_{U\in\mathbb{R}^{n\times k}, V\in\mathbb{R}^{k\times d}} \|A - UV\|_1.$$
3. The communication cost is as small as possible

Theorem 17.13.3. *Suppose $A \in \mathbb{R}^{n\times d}$ is partitioned in the row partition model (See Definition 17.13.1). There is a protocol(in Algorithm 17.11 without decomposition) which solves the problem in Definition 17.13.5 with constant probability. Further, the communication complexity of the protocol is $s(\mathrm{poly}(k) + \widetilde{O}(kd))$ words.*

Proof. **Correctness.** For convenience, we denote matrices $B \in \mathbb{R}^{n\times d}, S \in \mathbb{R}^{O(k\log^2 k)\times n}$ and $T_1 \in \mathbb{R}^{O(k\log^2 k)\times n}$ as
$$B = \begin{pmatrix} B_1 \\ B_2 \\ \cdots \\ B_s \end{pmatrix} \quad S = \begin{pmatrix} S_1 & S_2 & \cdots & S_s \end{pmatrix} \quad T_1 = \begin{pmatrix} T_{11} & T_{12} & \cdots & T_{1s} \end{pmatrix}.$$
Notice that $L = T_1BR, N = SBT_2, M = T_1BT_2$. Thus, $\widehat{X} \in \mathbb{R}^{O(k\log k)\times O(k\log k)}$ actually minimizes
$$\min_{\mathrm{rank}-k\ X} \|T_1BRXSBT_2 - T_1BT_2\|_F.$$

Also notice that B is just taking each row of A and replacing it with its nearest point in the row span of $S'A$. According to the proof of Theorem 17.4.6, $BR\widehat{X}SB$ gives a $\mathrm{poly}(k)\log d$ ℓ_1 norm rank-k approximation to A. Since $\widehat{X} = \widehat{U}\widehat{\Sigma}\widehat{V}^\top$, $V^* = \widehat{\Sigma}\widehat{V}^\top SB$ satisfies:

$$\min_{U\in\mathbb{R}^{n\times k}} \|A - UV^*\|_1 \leq \mathrm{poly}(k, \log(d), \log(n)) \cdot \min_{U\in\mathbb{R}^{n\times k}, V\in\mathbb{R}^{k\times d}} \|A - UV\|_1.$$

Communication complexity. Since the R and T_2 are $\widetilde{O}(kd)$-wise independent, line 6 needs $O(sW)$ bits of communication. Line 16 needs $O(sk^2\log^3 k)$ words. The cost of line 23 is $O(sk^2\log^2 k)$ words. Line 32 needs skd words of communication. Therefore, the total communication of the protocol is $s(\mathrm{poly}(k) + \widetilde{O}(kd))$ words.

□

17.13.5 Row-partition model, decomposition, $\mathrm{poly}(k)\log d$ approximation

Definition 17.13.6 (Row-partition model ℓ_1-low rank approximation - rank-k decomposition version)**.** Given matrix $A \in \mathbb{R}^{n\times d}$ row partitioned into s matrices $A_1, A_2, \cdots, A_s$ distributed in s machines respectively, and a positive integer $k < \mathrm{rank}(A)$, the goal is to propose a protocol in the model of Definition 17.13.1 such that

1. Upon termination, the protocol leaves matrices $U^* \in \mathbb{R}^{n\times k}, V^* \in \mathbb{R}^{k\times d}$ on the coordinator.

2. U^*, V^* satisfies that

$$\|A - U^*V^*\|_1 \leq \mathrm{poly}(k)\log d \cdot \min_{U\in\mathbb{R}^{n\times k}, V\in\mathbb{R}^{k\times d}} \|A - UV\|_1.$$

3. The communication cost is as small as possible.

Theorem 17.13.4. *Suppose $A \in \mathbb{R}^{n\times d}$ is partitioned in the row partition model (See Definition 17.13.1). There is a protocol(in Algorithm 17.11 with decomposition) which solves the problem in Definition 17.13.6 with constant probability. Further, the communication complexity of the protocol is $s(\mathrm{poly}(k) + \widetilde{O}(k(n+d)))$ words.*

Proof. **Correctness.** The only difference is that the above protocol sends U_i. Thus, the coordinator can compute $U^* = BR\widehat{U}$. Notice that $U^*V^* = BR\widehat{X}SB$, according to the proof of Theorem 17.4.6, U^*V^* gives a $\mathrm{poly}(k)\log d$ ℓ_1 norm rank-k approximation to A.

Communication complexity. Since the size of U_i is kn words, the total communication is $s(\mathrm{poly}(k) + \widetilde{O}(k(n+d)))$ words.

Chapter 18

L1 Low Rank Approximation with Regularization

Low rank matrix approximation with respect to the entrywise ℓ_1 norm error is a fundamental problem in both theoretical computer science and machine learning community. At the same time, ℓ_1 regularization (a.k.a. the LASSO) has been used for many statistical learning techniques on finding solutions with good performance and interpretability. In this paper, we consider how to combine the two techniques and study the ℓ_1 regularized version of ℓ_1-low rank approximation problem. In particular, given matrix $A \in \mathbb{R}^{n\times n}$, parameter $k \geq 1, \lambda > 0$, the problem we interested in is

$$\min_{U\in\mathbb{R}^{n\times k}, V\in\mathbb{R}^{k\times n}} \|UV - A\|_1 + \lambda(\|U\|_1 + \|V\|_1),$$

where $\|B\|_1 := \sum_{i=1}^{n}\sum_{j=1}^{n}|B_{i,j}|$ for any matrix B.

We introduce the first algorithm for solving this problem with probable guarantee. Precisely, we compute two matrices $U \in \mathbb{R}^{n\times k}$ and $V \in \mathbb{R}^{k\times n}$ such that

$$\|UV - A\|_1 + \lambda(\|U\|_1 + \|V\|_1) \leq \alpha\,\mathrm{OPT}$$

holds with probability at least 9/10, where OPT is the cost of the optimal solution, and α is approximation ratio.

In addition, our algorithm shows a trade-off between running time and approximation ratio:

- $O(\mathrm{nnz}(A)) + n\,\mathrm{poly}(\log n, k)$ time with $\alpha = \mathrm{poly}(k, \log n)$.
- $\widetilde{O}(k)\,\mathrm{nnz}(A) + n\,\mathrm{poly}(\log n, k)$ time with $\alpha = \widetilde{O}(k^2)\log^3 n$.

where $\mathrm{nnz}(A)$ denotes the number of non-zero entries in A.

18.1 Introduction

The low-rank matrix approximation is a core problem in machine learning and data mining. It approximating a matrix by one whose rank is less than that of the original matrix. The goal of low-rank approximation is to obtain more condensed representations of the data with limited loss of information. Given a matrix $A \in \mathbb{R}^{m\times n}$ and a desired rank k, the low-rank matrix approximation problem can be stated as

$$\min_{\widehat{A}\in\mathbb{R}^{m\times n}} \|\widehat{A} - A\| \quad \text{subject to} \quad \text{rank}(\widehat{A}) \leq k, \tag{18.1}$$

where $\|\cdot\|$ is a matrix norm measuring the approximation error.

Generally speaking, a rank-k matrix $\widehat{A} \in \mathbb{R}^{n\times n}$ can be expressed by the matrix product of two matrices U, V, where $U \in \mathbb{R}^{n\times k}$, $V \in \mathbb{R}^{k\times n}$. The above equation can be rewritten as

$$\min_{U\in\mathbb{R}^{n\times k}, V\in\mathbb{R}^{k\times n}} \|UV - A\|. \tag{18.2}$$

The key point in low-rank approximation problem is how to choose the matrix norm $\|\cdot\|$. The most widely used norm is the Frobenius norm, which is defined as $\|B\|_F = (\sum_{i=1}^{n}\sum_{j=1}^{n} B_{i,j}^2)^{\frac{1}{2}}$ for matrix $B \in \mathbb{R}^{n\times n}$, The analytical optimal solution for Frobenius norm can be obtained by using the singular value decomposition (SVD) of B.

The Frobenius norm fits well with Gaussian noise, but it is sensitive to sparse outliers. Thus, an interesting extension for solving (18.2) is when the noise is sparse. This problem can be written as

$$\min_{U\in\mathbb{R}^{n\times k}, V\in\mathbb{R}^{k\times n}} \|UV - A\|_0, \tag{18.3}$$

where $\|\cdot\|_0$ is ℓ_0 norm which measures the sparsity of the matrix.

Nevertheless, solving ℓ_0 low-rank approximation has been proven to be NP-hard [GG11]. In practice, instead of solving (18.3), a more feasible way is to solve

$$\min_{U \in \mathbb{R}^{n \times k}, V \in \mathbb{R}^{k \times n}} \|UV - A\|_1, \tag{18.4}$$

where we replace the ℓ_0 by ℓ_1, and $\|B\|_1 := \sum_{i=1}^{n} \sum_{j=1}^{n} |B_{i,j}|$ for matrix $B \in \mathbb{R}^{n \times n}$. This problem sometimes is referred to as robust PCA [CLMW11]. Finding solution to (18.4) has been widely studied by machine learning and theoretical computer science community for a long time. It has been validated both empirically and theoretically that ℓ_1-norm is usually more robust than ℓ_2-norm and tends to preserve the sparsity of the original matrix [CLMW11, XCS10, WY13, XCS11]. Also, ℓ_1 norm has been extensively studied in many other problems such as sparse recovery [PW11], Fourier transform [BCG+12], furthest pair [Yao82, GBT84], closest pair [PS85, DHKP97] and so on.

Although solving (18.4) has been proven to be NP-hard [GV15], there are a lot of efforts for the ℓ_1 low-rank approximation problem in a heuristic way. [KK05] introduced a method based on alternating convex minimization. [WYWY12] devise a parallelizable expectation-maximization (EM) algorithm which can potentially be applied to large-scale applications. [BDB13] exploit the efficient calculation of the optimal solution of the ℓ_1-norm best-fit hyperplane problem. Unfortunately, those heuristic method do not come with any performance guarantees. Recently, [SWZ17, CGK+17b] introduce efficient algorithms for ℓ_1-low rank approximation with provable approximation guarantees.

ℓ_1 regularization can be very effective for many statistical learning techniques [LZWW16, Tib96]. However, none of the previous ℓ_1 low rank approximation algorithms can handle the regularized version of ℓ_1 low rank approximation problem. Though [LZWW16] studies ℓ_1

principal component analysis problem with ℓ_1 regularization, their algorithm does not have any provable guarantee. [ACW17] studied regularized low rank approximation problem, but they can only deal with the regularized Frobenious norm low rank approximation, i.e. $\min_{U\in\mathbb{R}^{n\times k},V\in\mathbb{R}^{k\times n}} \|UV-A\|_F^2+\lambda(\|U\|_F^2+\|V\|_F^2)$, and their techniques cannot be extended to regularized ℓ_1 low rank approximation case. It is natural to ask whether there is an efficient algorithm for solving ℓ_1-regularized ℓ_1 low-rank approximation with a good approximation ratio.

In this work, we study the ℓ_1 regularized version of ℓ_1 low rank approximation problem. The problem can be formulated as

$$\min_{U\in\mathbb{R}^{n\times k},V\in\mathbb{R}^{k\times n}} \|UV-A\|_1+\lambda(\|U\|_1+\|V\|_1), \tag{18.5}$$

where λ is a non-negative tunable parameter which controls the weight between approximation error and the sparsity of U,V. When $\lambda=0$, (18.5) degenerates to (18.4). By solving (18.5), our model provides the flexibility that can find the balance between the reconstruction error and the sparsity of each low-rank component. Notably, when $\lambda=0$, our results exactly match the results shown in [SWZ17].

18.1.1 Our results

We give the first efficient algorithms for ℓ_1 low-rank approximation with ℓ_1 regularization problem with both provable running time and approximation ratio guarantees. A crucial tool in our algorithms is sketching, i.e. compressing the large input data into a small size summary which is enough to provide a good solution to the original input. In particular, we use the Cauchy transformation as our sketching tool. The Cauchy transformation is widely used in ℓ_1 numerical linear algebra problems such as subspace embedding

and linear regression (see e.g. [SW11, MM13]). However, people did not know how to use the Cauchy transformation technique to solve low-rank matrix approximation problem until recent work [SWZ17]. In our work, we show how to extend this technique to handle ℓ_1 regularization. But the analysis of the algorithms is very different from the previous works [SWZ17, SW11, MM13]. Algorithm 18.1 shows the framework of our algorithms.

There are different kind of the Cauchy transformations given by previous works [SW11, MM13, CDMI+13]. They have different trade-offs between distortion ratio and the running time of applying the transformation. By using different Cauchy transformation, we show algorithms with different running time/approximation ratio tradeoffs.

By using sparse Cauchy transform [MM13] (see Section 18.2.2), we can get the following result,

Theorem 18.1.1 (Input sparsity time algorithm)**.** *Given matrix $A \in \mathbb{R}^{n \times n}$, parameters $k \geq 1$, $\lambda > 0$, let* OPT *denote* $\min_{U' \in \mathbb{R}^{n \times k}, V' \in \mathbb{R}^{k \times n}} \|U'V' - A\|_1 + \lambda(\|U'\|_1 + \|V'\|_1)$*, there is an algorithm that runs in $O(\mathrm{nnz}(A) + n\,\mathrm{poly}(k, \log n))$ time to output two matrices $U \in \mathbb{R}^{n \times k}$, $V \in \mathbb{R}^{k \times n}$ such that,*

$$\|UV - A\|_1 + \lambda(\|U\|_1 + \|V\|_1) \leq \mathrm{poly}(k, \log n) \cdot \mathrm{OPT}$$

holds with probability at least $9/10$, where $\mathrm{nnz}(A)$ is the number of nonzeros in matrix A.

By using dense Cauchy transform [SW11] (see Section 18.2.2), we can get a different trade-off between approximation ration and running time. Theorem 18.1.1 provides a $\mathrm{nnz}(A)$ running time with $\mathrm{poly}(k, \log n)$-approximation. Here we provide a better approximation ratio under polynomial running time.

Theorem 18.1.2 ($\widetilde{O}(k^2)\,\mathrm{poly}(\log n)$-approximation)**.** *Given matrix $A \in \mathbb{R}^{n\times n}$, parameters $k \geq 1$, $\lambda > 0$, let* OPT *denote* $\min_{U'\in\mathbb{R}^{n\times k}, V'\in\mathbb{R}^{k\times n}} \|U'V' - A\|_1 + \lambda(\|U'\|_1 + \|V'\|_1)$*, there is an algorithm that runs in $\widetilde{O}(k)\cdot \mathrm{nnz}(A) + n\cdot \mathrm{poly}(k, \log n)$ time to output two matrices $U \in \mathbb{R}^{n\times k}$, $V \in \mathbb{R}^{k\times n}$ such that,*

$$\|UV - A\|_1 + \lambda(\|U\|_1 + \|V\|_1) \leq \widetilde{O}(k^2)\log^3 n \cdot \mathrm{OPT}$$

holds with probability at least $9/10$*.*

Notice that when $\lambda = 0$, all of our results exactly match the ℓ_1 low-rank approximation results shown by [SWZ17]. Since [SWZ17] also showed $k^{\Omega(1)}$ factor is necessary in the approximation ratio, our results are almost tight.

Algorithm 18.1 A Meta Algorithm

18.1.2 Technique overview

Sketching is used widely in many important numerical linear algebra problems such as overconstrained regression [CW13, DMMS11, MM13, NN13a, Sar06], low rank matrix

approximation [AM07, CW13, DV06, DKM06, MM13, NN13a, Sar06, CW15b, SWZ17, BWZ16] computation of leverage scores [CW13, DMIMW12, MM13, NN13a], regularized data fitting [ACW17]. Roughly speaking, the main idea of sketching is to highly compress the original data into a small size summary, and then to recover properties of the original data from the such small summary.

[SWZ17] proposed the first sketching based algorithm for solving ℓ_1 norm low rank matrix approximation problem. In that paper, they focused on the problem that given $A \in \mathbb{R}^{n \times n}, k > 0$, the goal is to solve

$$\min_{U \in \mathbb{R}^{n \times k}, V \in \mathbb{R}^{k \times n}} \|UV - A\|_1.$$

This problem is ℓ_1 norm low rank approximation problem, and it is a special case of our problem, i.e. when $\lambda = 0$. The main idea of [SWZ17] is as the following: for a given matrix $A \in \mathbb{R}^{n \times n}$, and a rank parameter k, they firstly chose two small random sketching matrices $S \in \mathbb{R}^{s \times n}$ and $R \in \mathbb{R}^{n \times r}$ and argued that there is a rank-k matrix B in the both small column span of AR and small row span of SA, and $\|B - A\|_1$ has a very good approximation ratio to the optimal cost, i.e. $\mathrm{poly}(k, \log n)$. Notice that B is in the both column space of AR and the row space of SA, it means that

$$\min_{X \in \mathbb{R}^{r \times k}, Y \in \mathbb{R}^{k \times s}} \|ARX \cdot YSA - A\|_1$$

is a good approximation of $\min_{\mathrm{rank}-k\ UV} \|UV - A\|_1$, and since the dimension of the column space of AR and the row space of SA are very small, then they further sketched down the problem by using oblivious ℓ_1 subspace embedding [MM13, SW11] or Lewis weights sampling [CP15]. Precisely, they chose additional two small random sketching matrices

$T_1 \in \mathbb{R}^{t_1 \times n}, T_2 \in \mathbb{R}^{n \times t_2}$, $(t_1, t_2 \leq \mathrm{poly}(k))$ and further sketched down the optimization problem to get a new minimization problem i.e.,

$$\min_{X \in \mathbb{R}^{r \times k}, Y \in \mathbb{R}^{k \times s}} \|T_1 AR \cdot X \cdot Y \cdot SAT_2 - T_1 AT_2\|_1.$$

Since the new optimization problem is very small, then it can be solved by relaxing to ℓ_2 minimization problem with losing mild additional $\mathrm{poly}(k)$ factors in approximation ratio or solved by using exponential running time optimizer with losing mild additional $2^{\mathrm{poly}(k)}$ running time, e.g. polynomial system verifier [Ren92a, Ren92b, BPR96, RSW16, SWZ17]. Now come back to our regularized ℓ_1 norm low rank approximation problem. We can find that we cannot extend the technique of [SWZ17] directly. Because our objective function is

$$\min_{\mathrm{rank}-k\ UV} \|UV - A\|_1 + \lambda(\|U\|_1 + \|V\|_1),$$

if λ is large, then the cost induced by $\|U\|_1 + \|V\|_1$ may dominate the cost induced by $\|UV - A\|_1$. Thus, the main issue we are facing is that it is not clear whether there is still a $\widehat{U}$ in the column space of AR such that

$$\min_{\mathrm{rank}-k\ V} \|\widehat{U}V - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|V\|_1)$$

has a good approximation ratio to the optimal cost (same issue appears for V, i.e. we are not sure whether there is a good $\widehat{V}$ in the row space of SA.) If we want to sketch $\|UV - A\|_1$, $\|U\|_1$ and $\|V\|_1$ separately, we can not get a $\mathrm{poly}(k)$ size sketch, since the freedom of U and V itself is too large, i.e. we cannot restrict them on any small subspace. Thus, it motivated us to look at the cost induced by $\|UV - A\|_1$, $\|U\|_1$ and $\|V\|_1$ at the same time. Suppose U^* is the optimal solution of

$$\min_{\mathrm{rank}-k\ UV} \|UV - A\|_1 + \lambda(\|U\|_1 + \|V\|_1).$$

Then we have $\min_{\text{rank}-k\ V} \|U^*V - A\|_1 + \lambda(\|U^*\|_1 + \|V\|_1) = \text{OPT}$. Notice that it is actually an ℓ_1 regression problem:

$$\min_{\text{rank}-k\ V} \left\| \begin{bmatrix} U^* \\ \lambda I \end{bmatrix} V - \begin{bmatrix} A \\ 0 \end{bmatrix} \right\|_1 + \lambda \|U^*\|_1.$$

We choose a small random sketching matrix S, and we proved that a good approximation for

$$\min_{\text{rank}-k\ V} \left\| \begin{bmatrix} SU^* \\ \lambda I \end{bmatrix} V - \begin{bmatrix} SA \\ 0 \end{bmatrix} \right\|_1 \tag{18.6}$$

is a good approximation for

$$\min_{\text{rank}-k\ V} \left\| \begin{bmatrix} U^* \\ \lambda I \end{bmatrix} V - \begin{bmatrix} A \\ 0 \end{bmatrix} \right\|_1 .$$

Notice that since S has only $\text{poly}(k)$ number of rows, the number of rows of

$$\begin{bmatrix} SU^* \\ \lambda I \end{bmatrix} V - \begin{bmatrix} SA \\ 0 \end{bmatrix}$$

is at most $\text{poly}(k)$. Thus, we can relax optimization problem (18.6) to

$$\min_{\text{rank}-k\ V} \sum_{i=1}^{n} \left\| \begin{bmatrix} SU^* \\ \lambda I \end{bmatrix} V_i - \begin{bmatrix} SA \\ 0 \end{bmatrix}_i \right\|_2$$

with at most $\text{poly}(k)$ factor loss in approximation ratio. For the above optimization problem, we can get the optimal solution which has form

$$\widehat{V} = \begin{bmatrix} SU^* \\ \lambda I \end{bmatrix}^\dagger \cdot \begin{bmatrix} SA \\ 0 \end{bmatrix} = \begin{bmatrix} SU^* \\ \lambda I \end{bmatrix}^\dagger \cdot \begin{bmatrix} I \\ 0 \end{bmatrix} \cdot SA.$$

Thus, we can prove that

$$\min_{\text{rank}-k\ U} \|U\widehat{V} - A\|_1 + \lambda(\|U\|_1 + \|\widehat{V}\|_1).$$

is a good approximation to OPT . Then, we choose a small random sketching matrix R, we can apply the "iterative existential proof" [SWZ19b] argument to show that there is a matrix $\widehat{U}$ in the column space of AR such that

$$\|\widehat{U}\widehat{V} - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|\widehat{V}\|_1)$$

is also a good approximation to OPT . Since $\widehat{U}$ is in the column space of AR and $\widehat{V}$ is in the row space of SA, we can get that

$$\min_{\mathrm{rank}-k\ XY} \|ARXYSA - A\|_1 + \lambda(\|ARX\|_1 + \|YSA\|_1)$$

is a good approximation to OPT . Because we shrink the solution space to a very small subspace, then we can use the oblivious subspace embedding [MM13, SW11] or Lewis weights sampling [CP15] to further choose two random sketching T_1, T_2 to sketch down the optimization problem to get

$$\min_{\mathrm{rank}-k\ XY} \|T_1ARXYSAT_2 - T_1AT_2\|_1 + \lambda(\|T_1ARX\|_1 + \|YSAT_2\|_1).$$

It is equivalent to solve

$$\min_{\mathrm{rank}-k\ XY} \left\| \begin{bmatrix} T_1ARX \\ \lambda I \end{bmatrix} \begin{bmatrix} YSAT_2 & \lambda I \end{bmatrix} - \begin{bmatrix} T_1AT_2 & 0 \\ 0 & \lambda^2 I \end{bmatrix} \right\|_1 .$$

To solve the above small problem, we can relax it into ℓ_2 version by losing $\mathrm{poly}(k)$ approximation factor or use some powerful optimizers by losing $2^{\mathrm{poly}(k)}$ running time. If we relax it into ℓ_2 version, then we need to solve

$$\min_{\mathrm{rank}-k\ XY} \left\| \begin{bmatrix} T_1ARX \\ \lambda I \end{bmatrix} \begin{bmatrix} YSAT_2 & \lambda I \end{bmatrix} - \begin{bmatrix} T_1AT_2 & 0 \\ 0 & \lambda^2 I \end{bmatrix} \right\|_F^2$$

which is

$$\min_{\text{rank}-k \ XY} \|T_1ARXYSAT_2 - T_1AT_2\|_F^2 + \lambda^2(\|T_1ARX\|_F^2 + \|YSAT_2\|_F^2).$$

It is exactly a generalized version of the Frobenius norm ridge low rank matrix approximation problem (see Section 18.2.1 for more details), and we can directly get the closed form of the optimal solution of this problem [ACW17, UHZ+16].

Surprisingly, we further showed that all the sketching matrices T_1, S, R, T_2 used in [SWZ17] satisfy the property we needed our problem. It means that we can actually fully generalize almost all the algorithms[1] in [SWZ17] to the ℓ_1 regularizer version.

[1]We can also generalize its CUR decomposition algorithms by using our techniques, but it is not the main focus in this work.

18.2 Preliminaries

In this Section, we mainly introduce the notations and some background knowledge.

For an $n \in \mathbb{N}_{\geq 0}$, let $[n]$ denote the set $\{1, 2, \cdots, n\}$.

For any function f, we define $\widetilde{O}(f)$ to be $f \cdot \log^{O(1)}(f)$. In addition to $O(\cdot)$ notation, for two functions f, g, we use the shorthand $f \lesssim g$ (resp. $\gtrsim$) to indicate that $f \leq Cg$ (resp. $\geq$) for an absolute constant C. We use $f \eqsim g$ to mean $cf \leq g \leq Cf$ for constants c, C.

Given a matrix $A \in \mathbb{R}^{n \times d}$, we say the set $\{y \mid x \in \mathbb{R}^d, y = Ax\}$ is the column space of A. Similarly, we say the set $\{y \mid x \in \mathbb{R}^n, y = x^\top A\}$ is the row space of A.

Let $\mathrm{nnz}(A)$ denote the number of nonzero entries of A. Let $\det(A)$ denote the determinant of a square matrix A. Let $A^\top$ denote the transpose of A. Let $A^\dagger$ denote the Moore-Penrose pseudoinverse of A. Let A^{-1} denote the inverse of a full rank square matrix.

Let $\|A\|_F$ denote the Frobenius norm of matrix A and $\|A\|_1$ denote the entry-wise 1-norm of matrix A.

18.2.1 Frobenius norm ridge low-rank approximation and ℓ_2 relaxation

In this Section, we introduce a highly related problem called Frobenius norm ridge low rank approximation problem. It is just an ℓ_2 variation of the problem we studied in this work:

$$\min_{U \in \mathbb{R}^{n \times k}, V \in \mathbb{R}^{k \times n}} \|UV - A\|_F^2 + \lambda(\|U\|_F^2 + \|V\|_F^2). \tag{18.7}$$

In [ACW17], they have an efficient algorithm for more generalized problem:

Theorem 18.2.1 (Lemma 27 in [ACW17]). *For $T_1 \in \mathbb{R}^{t_1 \times n}$, $T_2 \in \mathbb{R}^{n \times t_2}$, $B \in \mathbb{R}^{t_1 \times t_2}$, the problem of finding*

$$\min_{\widehat{X} \in \mathbb{R}^{n \times k}, \widehat{Y} \in \mathbb{R}^{k \times n}} \|T_1 \widehat{X} \widehat{Y} T_2 - B\|_F^2 + \lambda(\|T_1 \widehat{X}\|_F^2 + \|\widehat{Y} T_2\|_F^2)$$

and the minimizing $T_1 \widehat{X} \in \mathbb{R}^{t_1 \times k}$ and $\widehat{Y} T_2 \in \mathbb{R}^{k \times t_2}$, can be solved in $O(t_1 n \operatorname{rank}(T_1) + t_2 n \operatorname{rank}(T_2) + \operatorname{rank}(T_2) t_1 (t_2 + \operatorname{rank}(T_1)))$ time.

The following Claim shows the relation between the solution of ℓ_2 regression and the solution of ℓ_1 regression.

Claim 18.2.2 (ℓ_2 relaxation). *Let $A \in \mathbb{R}^{n \times d}$. We have $\|A\|_F \leq \|A\|_1 \leq \sqrt{nd} \|A\|_F$.*

Roughly speaking, our algorithms firstly sketch down the size of the input, and then relax the original problem to ℓ_2 case. The above lemma and the claim are fundamental building blocks in the reduction from the original problem to the ℓ_2 relaxation.

18.2.2 Cauchy transforms

In this section, we introduce the main sketching tool used in this work: the Cauchy transformation. We mainly introduce two kinds of Cauchy transformations: Dense Cauchy transform and Sparse Cauchy transform where each of them is introduced by [SW11] and [MM13] separately.

Definition 18.2.1 (Dense Cauchy transform [SW11]). Let $S = \sigma \cdot C \in \mathbb{R}^{m \times n}$ where σ is a scalar, and each entry of $C \in \mathbb{R}^{m \times n}$ is chosen independently from the standard Cauchy distribution. S is called Dense Cauchy transform matrix.

It is easy to see that for any $A \in \mathbb{R}^{n \times d}$, SA can be computed in $O(m \cdot \mathrm{nnz}(A))$ time [SW11].

Definition 18.2.2 (Sparse Cauchy transform [MM13])**.** Let $\Pi = \sigma \cdot SC \in \mathbb{R}^{m \times n}$, where σ is a scalar, $S \in \mathbb{R}^{m \times n}$ has each column chosen independently and uniformly from the m standard basis vectors of $\mathbb{R}^m$, and $C \in \mathbb{R}^{n \times n}$ is a diagonal matrix with diagonals chosen independently from the standard Cauchy distribution. Π is called Sparse Cauchy transform matrix.

For any matrix $A \in \mathbb{R}^{n \times d}$, ΠA can be computed in $O(\mathrm{nnz}(A))$ time. For any matrix $A \in \mathbb{R}^{n \times d_1 \times d_2}$, ΠA can be computed in $O(\mathrm{nnz}(A))$ time [MM13].

The properties of Cauchy transformation needed in this work is the following Lemma:

Lemma 18.2.3 (Lemma D.11 in [SWZ17])**.** *Given $M \in \mathbb{R}^{n \times d}, U \in \mathbb{R}^{n \times t}, d \geq t = \mathrm{rank}(U), n \geq d \geq r = \mathrm{rank}(M)$, if sketching matrix $S \in \mathbb{R}^{m \times n}$ is drawn from any of the following probability distributions of matrices, with .99 probability S satisfies the following properties:*

1. $\|SM\|_1 \leq c_1 \|M\|_1$,
2. $\forall x \in \mathbb{R}^t, \|SUx\|_1 \geq \frac{1}{c_2} \|Ux\|_1$,

where c_1, c_2 are parameters which depend on the distribution over S.

- *$S \in \mathbb{R}^{m \times n}$ is a dense Cauchy transform matrix: a matrix with i.i.d. entries drawn from the standard Cauchy distribution. If $m = O(t \log t)$, then $c_1 c_2 = O(\log d)$. If $m = O((t + r) \log(t + r))$, then $c_1 c_2 = O(\min(\log d, r \log r))$.*

- $S \in \mathbb{R}^{m \times n}$ *is a sparse Cauchy transform matrix:* $S = TD$*, where* $T \in \mathbb{R}^{m \times n}$ *has each column i.i.d. from the uniform distribution on standard basis vector of* $\mathbb{R}^m$*, and* $D \in \mathbb{R}^{n \times n}$ *is a diagonal matrix with i.i.d. diagonal entries from standard Cauchy distribution. If* $m = O(t^5 \log^5 t)$*, then* $c_1 c_2 = O(t^2 \log^2 t \log d)$*. If* $m = O((t+r)^5 \log^5(t+r))$*, then* $c_1 c_2 = O(t^2 \log^2 t \log d, r^3 \log^3 r)$*.*

In the above, if we replace S *with* $\sigma \cdot S$ *where* $\sigma \in \mathbb{R} \setminus \{0\}$ *is any scalar, then the relation between* m *and* $c_1 c_2$ *is still preserved.*

18.3 The Algorithm

Our algorithm is shown in Algorithm 18.1. If we choose all the sketching matrices S, R, T_1, T_2 as dense Cauchy transformation matrices (see Definition 18.2.1), then we are able to finally get Theorem 18.1.2. If we choose all the sketching matrices S, R, T_1, T_2 as sparse Cauchy transformation matrices (see Definition 18.2.2), then we are able to finally get Theorem 18.1.1.

For convenience, we define $\mathrm{OPT}(A, k, \lambda)$ as follows

$$\mathrm{OPT}(A, k, \lambda) = \min_{U \in \mathbb{R}^{n \times k}, V \in \mathbb{R}^{k \times n}} \|UV - A\|_1 + \lambda(\|U\|_1 + \|V\|_1).$$

If A, k, λ is clear from the context, we just use OPT to denote $\mathrm{OPT}(A, k, \lambda)$.

Then we present the analysis of our algorithm in the following way:

1. In Section 18.3.1, we show how to reduce the original problem to the following problem,

$$\min_{X \in \mathbb{R}^{r \times k}, Y \in \mathbb{R}^{k \times s}} \|ARXYSA - A\|_1 + \lambda(\|ARX\|_1 + \|YSA\|_1).$$

2. In Section 18.3.2, we show how to further reduce the above problem to:

$$\min_{X \in \mathbb{R}^{r \times k}, Y \in \mathbb{R}^{k \times s}} \|T_1 ARXYSAT_2 - T_1 AT_2\|_1 + \lambda(\|T_1 ARX\|_1 + \|YSAT_2\|_1).$$

3. Finally, in Section 18.3.3, we show how to solve the above problem with a small approximation ratio.

18.3.1 Sketching Lemmas

In this section, we show how to use sketching techniques to prove Corollary 18.3.2 which means that there is a good approximate solution whose columns are in the column space of AR and rows are in the row space of SA where S, A are two sketching matrices (shown in the algorithm 18.1) which satisfy desired properties. Before proving Corollary 18.3.2, we first prove the following lemma which is a "one-side" version of the corollary: it shows that there is a good approximate solution in the row space of SA.

Lemma 18.3.1. (Existence of a good solution in a small column subspace)**.** Given matrix $A \in \mathbb{R}^{n\times n}$, $\alpha \geq 1, \beta \geq 1, \gamma \geq 1, \lambda > 0$ and $k \geq 1$. Let $\widehat{U} \in \mathbb{R}^{n\times k}$ satisfy

$$\min_{V\in\mathbb{R}^{k\times n}} \|\widehat{U}V - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|V\|_1) \leq \gamma\,\mathrm{OPT}\,.$$

Let $V^* \in \mathbb{R}^{k\times n}$ denote the optimal solution of

$$\min_{V\in\mathbb{R}^{k\times n}} \|\widehat{U}V - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|V\|_1).$$

Let matrix $S \in \mathbb{R}^{m\times n}$ satisfy:

$$\|S\widehat{U}x\|_1 \geq \frac{1}{\alpha}\|\widehat{U}x\|_1 \text{ for all } x \in \mathbb{R}^k,$$
$$\text{and } \|S\widehat{U}V^* - SA\|_1 \leq \beta\|\widehat{U}V^* - A\|_1.$$

Let $\widehat{V} \in \mathbb{R}^{k\times n}$ denote $\begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix}^\dagger \cdot \begin{bmatrix} I \\ 0 \end{bmatrix} \cdot SA$. Then

$$\|\widehat{U}\widehat{V} - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|\widehat{V}\|_1) \leq \alpha\beta\gamma(\sqrt{m+k}+2)\,\mathrm{OPT}\,.$$

Proof. Due to the space limitation, we provide the proofs in Appendix 18.4. □

Corollary 18.3.2 (Existence of a good solution in both row and column subspace)**.** *Given matrix $A \in \mathbb{R}^{n\times n}$, $\alpha_1, \beta_1, \alpha_2, \beta_2 \geq 1, \lambda > 0$ and $k \geq 1$. Let $U^* \in \mathbb{R}^{n\times k}, V^* \in \mathbb{R}^{k\times n}$ denote the optimal solution of the problem,*

$$\min_{U,V} \|UV - A\|_1 + \lambda(\|U\|_1 + \|V\|_1).$$

Let matrix $S \in \mathbb{R}^{s\times n}$ satisfy :

$$\begin{aligned} &\|SU^*x\|_1 \geq \frac{1}{\alpha_1}\|U^*x\|_1 \text{ for all } x \in \mathbb{R}^k \\ &\text{and } \|SU^*V^* - SA\|_1 \leq \beta_1\|U^*V^* - A\|_1. \end{aligned}$$

Let $\widehat{V} \in \mathbb{R}^{k\times n}$ denote $\begin{bmatrix} SU^* \\ \lambda I \end{bmatrix}^\dagger \cdot \begin{bmatrix} I \\ 0 \end{bmatrix} \cdot SA$. Let $\widetilde{U} \in \mathbb{R}^{n\times k}$ denote the optimal solution of

$$\min_{U\in\mathbb{R}^{n\times k}} \|U\widehat{V} - A\|_1 + \lambda(\|U\|_1 + \|\widehat{V}\|_1).$$

Let $R^\top \in \mathbb{R}^{r\times n}$ satisfy:

$$\begin{aligned} &\|R^\top\widehat{V}^\top x\|_1 \geq \frac{1}{\alpha_2}\|\widehat{V}^\top x\|_1 \text{ for all } x \in \mathbb{R}^k, \\ &\text{and } \|R^\top\widehat{V}^\top\widetilde{U}^\top - R^\top A^\top\|_1 \leq \beta_2\|\widehat{V}^\top\widetilde{U}^\top - A^\top\|_1. \end{aligned}$$

Let $\widehat{U}^\top \in \mathbb{R}^{k\times n}$ denote $\begin{bmatrix} R^\top\widehat{V}^\top \\ \lambda I \end{bmatrix}^\dagger \cdot \begin{bmatrix} I \\ 0 \end{bmatrix} \cdot R^\top A^\top$. Then

$$\begin{aligned} &\|\widehat{U}\widehat{V} - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|\widehat{V}\|_1) \\ &\leq 4(\alpha_1\beta_1\alpha_2\beta_2)(\sqrt{s+k}+2)(\sqrt{r+k}+2)\,\mathrm{OPT}, \end{aligned}$$

and there exists $X \in \mathbb{R}^{r\times k}, Y \in \mathbb{R}^{k\times s}$ such that

$$\|ARXYSA - A\|_1 + \lambda(\|ARX\|_1 + \|YSA\|_1) \leq \|\widehat{U}\widehat{V} - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|\widehat{V}\|_1).$$

Proof. It is actually applying Lemma 18.3.1 twice. Due to the property of sketching matrix S, we can apply Lemma 18.3.1 to get

$$\begin{aligned}
&\min_{U\in\mathbb{R}^{n\times k}} \|U\widehat{V} - A\|_1 + \lambda(\|U\|_1 + \|\widehat{V}\|_1) \\
\leq\ & \|U^*\widehat{V} - A\|_1 + \lambda(\|U^*\|_1 + \|\widehat{V}\|_1) \\
\leq\ & 2\alpha_1\beta_1(\sqrt{s+k}+2)\,\mathrm{OPT}\,.
\end{aligned}$$

We set $\gamma = 2\alpha_1\beta_1(\sqrt{s+k}+2)$. Due to the property of sketching matrix R, we can apply Lemma 18.3.1 again to get

$$\begin{aligned}
&\|\widehat{U}\widehat{V} - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|\widehat{V}\|_1) \\
\leq\ & 2\alpha_2\beta_2\gamma(\sqrt{r+k}+2)\,\mathrm{OPT} \\
=\ & 4\alpha_1\beta_1\alpha_2\beta_2(\sqrt{s+k}+2)(\sqrt{r+k}+2)\,\mathrm{OPT}\,.
\end{aligned}$$

Notice that $\widehat{U}$ is in the column space of AR, $\widehat{V}$ is in the row space of SA, thus,

$$\begin{aligned}
&\min_{X\in\mathbb{R}^{r\times k}, Y\in\mathbb{R}^{k\times s}} \|ARXYSA - A\|_1 \\
&\quad + \lambda(\|ARX\|_1 + \|YSA\|_1) \\
\leq\ & \|\widehat{U}\widehat{V} - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|\widehat{V}\|_1) \\
\leq\ & 4\alpha_1\beta_1\alpha_2\beta_2(\sqrt{s+k}+2)(\sqrt{r+k}+2)\,\mathrm{OPT}\,.
\end{aligned}$$

□

The above corollary shows that if we can find a good approximate solution $\widehat{X}, \widehat{Y}$ to

$$\min_{X\in\mathbb{R}^{r\times k}, Y\in\mathbb{R}^{k\times s}} \|ARXYSA - A\|_1 + \lambda(\|ARX\|_1 + \|YSA\|_1),$$

then we can have a good approximation $U = AR\widehat{X}, V = \widehat{Y}SA$ to the original problem.

18.3.2 Reducing to small problems

In the last section, we already restrict the solution in a low dimensional column space and in a low dimensional row space. But the problem size is till too large since the size of A is still n-by-n. In this section, we further sketch down the size of the input. The Corollary 18.3.4 shows how to further reduce the problem to solving

$$\min_{X\in\mathbb{R}^{r\times k},Y\in\mathbb{R}^{k\times s}} \|T_1ARXYSAT_2 - T_1AT_2\|_1 + \lambda(\|T_1ARX\|_1 + \|YSAT_2\|_1)$$

where T_1, T_2 are two sketching matrices with some desired properties. Before proving Corollary 18.3.4, let us look at the following lemma which provides a "one-side" sketch version of that corollary:

Lemma 18.3.3. (Reducing the problem size by sketching on one side)**.** Given three matrices $L \in \mathbb{R}^{d_1\times l_1}$, $M^\top \in \mathbb{R}^{d_2\times l_2}$, $N \in \mathbb{R}^{d_1\times d_2}$ and $\alpha \geq 1, \beta \geq 1, \gamma \geq 1, \lambda > 0$. Let $\mathrm{OPT} = \min_{X,Y} \|LXYM - N\|_1 + \lambda(\|LX\|_1 + \|YM\|_1)$. Let X^*, Y^* denote the optimal solution of

$$\min_{X,Y} \|LXYM - N\|_1 + \lambda(\|LX\|_1 + \|YM\|_1).$$

Let $T \in \mathbb{R}^{t\times d_1}$ satisfy :

$$\|TLx\|_1 \geq \frac{1}{\alpha}\|Lx\|_1, \text{ for all } x \in \mathbb{R}^{l_1}$$

and

$$\|TLX^*Y^*M - TN\|_1 + \lambda \cdot \|TLX^*\|_1$$
$$\leq \beta(\|LX^*Y^*M - N\|_1 + \lambda \cdot \|LX^*\|_1)$$

Let $\widehat{X}, \widehat{Y}$ satisfy

$$\begin{aligned}&\|TL\widehat{X}\widehat{Y}M - TN\|_1 + \lambda \cdot (\|TL\widehat{X}\|_1 + \|\widehat{Y}M\|_1) \\ \leq\ & \gamma \min_{X,Y} \|TLXYM - TN\|_1 + \lambda \cdot (\|TLX\|_1 + \|YM\|_1)\end{aligned}$$

Then

$$\begin{aligned}&\|L\widehat{X}\widehat{Y}M - N\|_1 + \lambda(\|L\widehat{X}\|_1 + \|\widehat{Y}M\|_1) \\ \leq\ & (\alpha\beta\gamma + \alpha\beta + 1)\,\mathrm{OPT}\,.\end{aligned}$$

Proof. Due to space limitation, we provide the proofs in Appendix 18.5. □

Corollary 18.3.4 (Reducing the problem size by sketching on both sides)**.** *Given three matrices* $L \in \mathbb{R}^{d_1 \times l_1}$, $M^\top \in \mathbb{R}^{d_2 \times l_2}$, $N \in \mathbb{R}^{d_1 \times d_2}$ *and* $\alpha_1 \geq 1, \alpha_2 \geq 1, \beta_1 \geq 1, \beta_2 \geq 1, \gamma \geq 1, \lambda > 0$. *Let* $\mathrm{OPT} = \min_{X,Y} \|LXYM - N\|_1 + \lambda(\|LX\|_1 + \|YM\|_1)$. *Let* X^*, Y^* *denote the optimal solution of*

$$\min_{X,Y} \|LXYM - N\|_1 + \lambda(\|LX\|_1 + \|YM\|_1).$$

Let $T_1 \in \mathbb{R}^{t_1 \times d_1}$ *satisfy : for all* $x \in \mathbb{R}^{l_1}$

$$\|T_1 Lx\|_1 \geq \frac{1}{\alpha_1}\|Lx\|_1$$

and

$$\begin{aligned}&\|T_1 LX^*Y^*M - T_1 N\|_1 + \lambda \cdot \|T_1 LX^*\|_1 \\ \leq\ & \beta_1(\|LX^*Y^*M - N\|_1 + \lambda \cdot \|LX^*\|_1)\end{aligned}$$

Let $\widehat{X}, \widehat{Y}$ the optimal solution

$$\min_{X,Y} \|T_1 L X Y M - T_1 N\|_1 + \lambda \cdot (\|T_1 L X\|_1 + \|Y M\|_1).$$

Let $T_2^\top \in \mathbb{R}^{t_2 \times d_2}$ satisfy : for all $x \in \mathbb{R}^{l_2}$

$$\|T_2^\top M^\top x\|_1 \geq \frac{1}{\alpha_2} \|M^\top x\|_1$$

and

$$\begin{aligned} &\|T_1 L \widehat{X} \widehat{Y} M T_2 - T_1 N T_2\|_1 + \lambda \cdot \|\widehat{Y} M T_2\|_1 \\ \leq\ & \beta_2 (\|T_1 L \widehat{X} \widehat{Y} M - T_1 N\|_1 + \lambda \cdot \|\widehat{Y} M\|_1) \end{aligned}$$

Let $\widetilde{X}, \widetilde{Y}$ satisfy

$$\begin{aligned} &\|T_1 L \widetilde{X} \widetilde{Y} M L_2 - T_1 N T_2\|_1 + \lambda (\|T_1 L \widetilde{X}\|_1 + \|M \widetilde{Y} T_2\|_1) \\ \leq\ & \gamma \min_{X,Y} \|T_1 L X Y M L_2 - T_1 N T_2\|_1 + \lambda (\|T_1 L X\|_1 + \|M Y T_2\|_1) \end{aligned}$$

Then

$$\begin{aligned} &\|L \widetilde{X} \widetilde{Y} M - N\|_1 + \lambda (\|L \widetilde{X}\|_1 + \|M \widetilde{Y}\|_1) \\ \leq\ & 9 \alpha_1 \alpha_2 \beta_1 \beta_2 \gamma \, \mathrm{OPT} \, . \end{aligned}$$

Proof. This follows by applying Lemma 18.3.3 twice. Due to the property of T_2 and the definition of $\widetilde{X}, \widetilde{Y}$, by applying Lemma 18.3.3, we have that

$$\begin{aligned} &\|T_1 L \widetilde{X} \widetilde{Y} M - T_1 N\|_1 + \lambda \cdot (\|T_1 L \widetilde{X}\|_1 + \|\widetilde{Y} M\|_1) \\ \leq\ & (\alpha_2 \beta_2 \gamma + \alpha_2 \beta_2 + 1) \Big(\|T_1 L \widehat{X} \widehat{Y} M - T_1 N\|_1 + \lambda \cdot (\|T_1 L \widehat{X}\|_1 + \|\widehat{Y} M\|_1) \Big). \end{aligned}$$

Now we set the new $\gamma' = (\alpha_2\beta_2\gamma + \alpha_2\beta_2 + 1)$. Then, due to the property of T_1 and the definition of $\widehat{X}, \widehat{Y}$, we can apply Lemma 18.3.3 again, we then have

$$\begin{aligned} & \|L\widetilde{X}\widetilde{Y}M - N\|_1 + \lambda(\|L\widetilde{X}\|_1 + \|M\widetilde{Y}\|_1) \\ \leq & (\alpha_1\beta_1\gamma' + \alpha_1\beta_1 + 1)\,\mathrm{OPT}\,. \end{aligned}$$

Since $\alpha_1, \alpha_2, \beta_1, \beta_2 \geq 1$, we then have $(\alpha_1\beta_1\gamma' + \alpha_1\beta_1 + 1) \leq 3\alpha_1\beta_1\gamma' \leq 9\alpha_1\beta_1\alpha_2\beta_2\gamma$. □

Let us set $L = AR, M = SA, N = A$, then due to the above corollary, we show that once we get a good approximation $\widetilde{X}, \widetilde{Y}$ to $\min_{X,Y} \|T_1ARXYSAT_2 - T_1AT_2\|_1 + \lambda(\|T_1ARX\|_1 + \|YSAT_2\|_1)$, we get a good approximation to $\min_{X,Y} \|ARXYSA - A\|_1 + \lambda(\|ARX\|_1 + \|YSA\|_1)$. Since the number of rows of T_1 is small and the number of columns of T_2 is also small, the problem size becomes very small. In the next section, we will see how to use the ℓ_2 relaxation to solve the small problem.

18.3.3 Solving small problems

In this section, we focus on solving

$$\min_{X,Y} \|T_1ARXYSAT_2 - T_1AT_2\|_1 + \lambda(\|T_1ARX\|_1 + \|YSAT_2\|_1).$$

Firstly, we have the following easy fact.

Fact 18.3.5. *Given five matrices L, X, Y, M and N with matching dimensions, we have*

$$\begin{aligned} & \|LXYM - N\|_1 + \lambda(\|LX\|_1 + \|YM\|_1) \\ = & \left\| \begin{bmatrix} LX \\ \lambda I \end{bmatrix} \cdot \begin{bmatrix} YM & \lambda I \end{bmatrix} - \begin{bmatrix} N & 0 \\ 0 & \lambda^2 I \end{bmatrix} \right\|_1 . \end{aligned}$$

We define $f(X,Y)$ as follows

$$f(X,Y) = \begin{bmatrix} T_1 ARX \\ \lambda I \end{bmatrix} \cdot \begin{bmatrix} YSAT_2 & \lambda I \end{bmatrix} - \begin{bmatrix} T_1 AT_2 & 0 \\ 0 & \lambda^2 I \end{bmatrix}. \tag{18.8}$$

Due to the above fact, we can relax the ℓ_1-norm minimization problem

$$\min_{X \in \mathbb{R}^{r \times k}, Y \in \mathbb{R}^{k \times s}} \|f(X,Y)\|_1 \tag{18.9}$$

to Frobenius norm minimization problem

$$\min_{X \in \mathbb{R}^{r \times k}, Y \in \mathbb{R}^{k \times s}} \|f(X,Y)\|_F ,$$

which is equivalent to

$$\min_{X \in \mathbb{R}^{r \times k}, Y \in \mathbb{R}^{k \times s}} \|f(X,Y)\|_F^2 . \tag{18.10}$$

Lemma 18.3.6 (Relaxing ℓ_1 norm to Frobenius norm)**.** *Given $A \in \mathbb{R}^{n \times n}$, $T_1 \in \mathbb{R}^{t_1 \times n}$, $T_2 \in \mathbb{R}^{n \times t_2}$, $R \in \mathbb{R}^{n \times r}$ and $S \in \mathbb{R}^{s \times n}$. Let $f_{T_1,T_2,R,S,A,\lambda}(X,Y) \in \mathbb{R}^{(t_1+k)\times(t_2+k)}$ be defined in Eq. (18.8), if X', Y' satisfies that*

$$\|f(X',Y')\|_F^2 \leq (1+\epsilon) \min_{X,Y} \|f(X,Y)\|_F^2$$

for some $\epsilon > 0$, then we have

$$\|f(X',Y')\|_1 \leq \sqrt{t_1+k} \cdot \sqrt{t_2+k} \cdot \sqrt{1+\epsilon} \min_{X,Y} \|f(X,Y)\|_1.$$

Proof. Let X^*, Y^* satisfy $\|f(X^*, Y^*)\|_1 = \min_{X,Y} \|f(X,Y)\|_1$. We have:

$$\begin{aligned}
& \|f(X', Y')\|_1 \\
\leq & \sqrt{t_1 + k} \cdot \sqrt{t_2 + k} \cdot \|f(X', Y')\|_F \\
\leq & \sqrt{t_1 + k} \cdot \sqrt{t_2 + k} \cdot \sqrt{1+\epsilon} \cdot \min_{X,Y} \|f(X,Y)\|_F \\
\leq & \sqrt{t_1 + k} \cdot \sqrt{t_2 + k} \cdot \sqrt{1+\epsilon} \cdot \|f(X^*, Y^*)\|_F \\
\leq & \sqrt{t_1 + k} \cdot \sqrt{t_2 + k} \cdot \sqrt{1+\epsilon} \cdot \|f(X^*, Y^*)\|_1
\end{aligned}$$

where the first inequality and the last inequality follow the Claim 18.2.2. □

Therefore, we can reduce the entry-wise ℓ_1 problem (18.9) to Frobenius norm problem (18.10).

Using the Theorem 18.2.1, we can solve the Frobenius norm problem (18.10). Now, we are ready to present our main results.

Theorem 18.3.7 (Restatement of Theorem 18.1.1)**.** *Given matrix $A \in \mathbb{R}^{n \times n}$, parameters $k \geq 1$, $\lambda > 0$, let* OPT *denote* $\min_{U' \in \mathbb{R}^{n \times k}, V' \in \mathbb{R}^{k \times n}} \|U'V' - A\|_1 + \lambda(\|U'\|_1 + \|V'\|_1)$*, there is an algorithm that runs in $O(\mathrm{nnz}(A) + n\,\mathrm{poly}(k, \log n))$ time to output two matrices $U \in \mathbb{R}^{n \times k}$, $V \in \mathbb{R}^{k \times n}$ such that,*

$$\|UV - A\|_1 + \lambda(\|U\|_1 + \|V\|_1) \leq \mathrm{poly}(k, \log n) \cdot \mathrm{OPT},$$

holds with probability at least $9/10$.

Proof. Due to the space limits, we put the whole proof into Appendix 18.6. □

Theorem 18.3.8 (Restatement of Theorem 18.1.2)**.** *Given matrix $A \in \mathbb{R}^{n \times n}$, parameters $k \geq 1$, $\lambda > 0$, let* OPT *denote* $\min_{U' \in \mathbb{R}^{n \times k}, V' \in \mathbb{R}^{k \times n}} \|U'V' - A\|_1 + \lambda(\|U'\|_1 + \|V'\|_1)$*, there is an algorithm that runs in* $\widetilde{O}(k) \cdot \mathrm{nnz}(A) + n \cdot \mathrm{poly}(k, \log n)$ *time to output two matrices $U \in \mathbb{R}^{n \times k}$, $V \in \mathbb{R}^{k \times n}$ such that,*

$$\|UV - A\|_1 + \lambda(\|U\|_1 + \|V\|_1) \leq \widetilde{O}(k^2) \log^3 n \cdot \mathrm{OPT},$$

holds with probability at least $9/10$*.*

Proof. Due to the space limits, we put the whole proof into Appendix 18.7. □

Remark 18.3.1. Combining our new technique with p-stable transform (e.g. Section E of [SWZ17] and [SWZ19b]), all of our results can be extended to ℓ_p-norm, where $1 < p < 2$.

18.4 Proof of Lemma 18.3.1

Lemma 18.3.1. (Existence of a good solution in a small column subspace)**.** Given matrix $A \in \mathbb{R}^{n\times n}$, $\alpha \geq 1, \beta \geq 1, \gamma \geq 1, \lambda > 0$ and $k \geq 1$. Let $\widehat{U} \in \mathbb{R}^{n\times k}$ satisfy

$$\min_{V\in\mathbb{R}^{k\times n}} \|\widehat{U}V - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|V\|_1) \leq \gamma\,\mathrm{OPT}\,.$$

Let $V^* \in \mathbb{R}^{k\times n}$ denote the optimal solution of

$$\min_{V\in\mathbb{R}^{k\times n}} \|\widehat{U}V - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|V\|_1).$$

Let matrix $S \in \mathbb{R}^{m\times n}$ satisfy:

$$\begin{aligned} &\|S\widehat{U}x\|_1 \geq \frac{1}{\alpha}\|\widehat{U}x\|_1 \text{ for all } x \in \mathbb{R}^k, \\ &\text{and } \|S\widehat{U}V^* - SA\|_1 \leq \beta\|\widehat{U}V^* - A\|_1. \end{aligned}$$

Let $\widehat{V} \in \mathbb{R}^{k\times n}$ denote $\begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix}^\dagger \cdot \begin{bmatrix} I \\ 0 \end{bmatrix} \cdot SA$. Then

$$\|\widehat{U}\widehat{V} - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|\widehat{V}\|_1) \leq \alpha\beta\gamma(\sqrt{m+k}+2)\,\mathrm{OPT}\,.$$

Proof. We can show the following Claim,

Claim 18.4.1.

$$\|\widehat{U}\widehat{V} - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|\widehat{V}\|_1) \leq \alpha \left\| \begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix} \widehat{V} - \begin{bmatrix} SA \\ 0 \end{bmatrix} \right\|_1 + \alpha \left\| \begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix} V^* - \begin{bmatrix} SA \\ 0 \end{bmatrix} \right\|_1 + \gamma\,\mathrm{OPT}\,.$$

Proof.

$$
\begin{aligned}
& \|\widehat{U}\widehat{V} - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|\widehat{V}\|_1) \\
= & \left\| \begin{bmatrix} \widehat{U} \\ \lambda I \end{bmatrix} \widehat{V} - \begin{bmatrix} A \\ 0 \end{bmatrix} \right\|_1 + \lambda \|\widehat{U}\|_1 \\
\leq & \left\| \begin{bmatrix} \widehat{U} \\ \lambda I \end{bmatrix} (\widehat{V} - V^*) \right\|_1 + \left\| \begin{bmatrix} \widehat{U} \\ \lambda I \end{bmatrix} V^* - \begin{bmatrix} A \\ 0 \end{bmatrix} \right\|_1 + \lambda \|\widehat{U}\|_1 \\
\leq & \left\| \begin{bmatrix} \widehat{U} \\ \lambda I \end{bmatrix} (\widehat{V} - V^*) \right\|_1 + \gamma \, \mathrm{OPT} \\
= & \|\widehat{U}(\widehat{V} - V^*)\|_1 + \lambda \|\widehat{V} - V^*\|_1 + \gamma \, \mathrm{OPT} \\
\leq & \alpha \|S\widehat{U}(\widehat{V} - V^*)\|_1 + \lambda \|\widehat{V} - V^*\|_1 + \gamma \, \mathrm{OPT} \\
\leq & \alpha \|S\widehat{U}(\widehat{V} - V^*)\|_1 + \lambda\alpha \|\widehat{V} - V^*\|_1 + \gamma \, \mathrm{OPT} \\
= & \alpha \left\| \begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix} (\widehat{V} - V^*) \right\|_1 + \gamma \, \mathrm{OPT} \\
\leq & \alpha \left\| \begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix} \widehat{V} - \begin{bmatrix} SA \\ 0 \end{bmatrix} \right\|_1 + \alpha \left\| \begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix} V^* - \begin{bmatrix} SA \\ 0 \end{bmatrix} \right\|_1 + \gamma \, \mathrm{OPT}
\end{aligned}
$$

where the second step follows by triangle inequality, the third step follows by

$$
\left\| \begin{bmatrix} \widehat{U} \\ \lambda I \end{bmatrix} V^* - \begin{bmatrix} A \\ 0 \end{bmatrix} \right\|_1 + \lambda \|\widehat{U}\|_1 \leq \gamma \, \mathrm{OPT},
$$

the fifth step follows by $\|\widehat{U}(\widehat{V} - V^*)\|_1 \leq \alpha \|S\widehat{U}(\widehat{V} - V^*)\|_1$, the sixth step follows by $\alpha \geq 1$, the eighth step follows by triangle inequality.

□

We now show how to bound the second term on RHS of the equation shown in Claim 18.4.1.

Claim 18.4.2.

$$\alpha \left\| \begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix} V^* - \begin{bmatrix} SA \\ 0 \end{bmatrix} \right\|_1 \leq \alpha\beta\gamma \, \mathrm{OPT} \, .$$

Proof. We have

$$\begin{aligned} & \alpha \left\| \begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix} V^* - \begin{bmatrix} SA \\ 0 \end{bmatrix} \right\|_1 \\ &= \alpha \| S(\widehat{U}V^* - A) \|_1 + \alpha\lambda \|V^*\|_1 \\ &\leq \alpha\beta \|\widehat{U}V^* - A\|_1 + \alpha\lambda \|V^*\|_1 \\ &\leq \alpha\beta \|\widehat{U}V^* - A\|_1 + \alpha\beta\lambda \|V^*\|_1 + \alpha\beta\lambda \|\widehat{U}\|_1 \\ &\leq \alpha\beta\gamma \, \mathrm{OPT}, \end{aligned}$$

the second step follows by $\|S(\widehat{U}V^* - A)\|_1 \leq \beta \|\widehat{U}V^* - A\|_1$. □

We show how to bound the first term on RHS of Claim 18.4.1,

Claim 18.4.3.

$$\alpha \left\| \begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix} \widehat{V} - \begin{bmatrix} SA \\ 0 \end{bmatrix} \right\|_1 \leq \alpha\beta\sqrt{m+k} \, \mathrm{OPT} \, .$$

Proof. We have

$$
\begin{aligned}
&\alpha \left\| \begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix} \widehat{V} - \begin{bmatrix} SA \\ 0 \end{bmatrix} \right\|_1 \\
&= \alpha \sum_{i=1}^{n} \left\| \begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix} \widehat{V}_i - \begin{bmatrix} SA_i \\ 0 \end{bmatrix} \right\|_1 \\
&\leq \alpha \sqrt{m+k} \sum_{i=1}^{n} \left\| \begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix} \widehat{V}_i - \begin{bmatrix} SA_i \\ 0 \end{bmatrix} \right\|_2 \\
&\leq \alpha \sqrt{m+k} \sum_{i=1}^{n} \left\| \begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix} V_i^* - \begin{bmatrix} SA_i \\ 0 \end{bmatrix} \right\|_2 \\
&\leq \alpha \sqrt{m+k} \sum_{i=1}^{n} \left\| \begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix} V_i^* - \begin{bmatrix} SA_i \\ 0 \end{bmatrix} \right\|_1 \\
&= \alpha \sqrt{m+k} \left\| \begin{bmatrix} S\widehat{U} \\ \lambda I \end{bmatrix} V^* - \begin{bmatrix} SA \\ 0 \end{bmatrix} \right\|_1 \\
&= \alpha \sqrt{m+k} (\|S\widehat{U}V^* - SA\|_1 + \lambda \|V^*\|_1) \\
&\leq \alpha \sqrt{m+k} (\beta \|\widehat{U}V^* - A\|_1 + \lambda \|V^*\|_1) \\
&\leq \alpha\beta \sqrt{m+k}\, \mathrm{OPT}
\end{aligned}
$$

where the second step follows by $\forall d \in \mathbb{Z}_{>0}, x \in \mathbb{R}^d, \|x\|_1 \leq \sqrt{d}\|x\|_2$, the third step follows by definition of $\widehat{V}$, the fourth step follows by $\forall d \in \mathbb{Z}_{>0}, x \in \mathbb{R}^d \ \|x\|_2 \leq \|x\|_1$, the seventh step follows by $\|S\widehat{U}V^* - SA\|_1 \leq \beta \|\widehat{U}V^* - A\|_1$, and the last step follows by $\beta \geq 1, \lambda \|\widehat{U}\|_1 \geq 0$. $\square$

Putting it all together, we

$$
\begin{aligned}
&\|\widehat{U}\widehat{V} - A\|_1 + \lambda(\|\widehat{U}\|_1 + \|\widehat{V}\|_1) \\
&\leq \alpha\beta \sqrt{m+k}\, \mathrm{OPT} + \alpha\beta\gamma\, \mathrm{OPT} + \gamma\, \mathrm{OPT} \\
&\leq \alpha\beta \sqrt{m+k}\, \mathrm{OPT} + 2\alpha\beta\gamma\, \mathrm{OPT} \\
&\leq \alpha\beta\gamma(\sqrt{m+k} + 2)\, \mathrm{OPT},
\end{aligned}
$$

where the first step follows by Claim 18.4.1, Claim 18.4.2 and Claim 18.4.3, the second step follows by $\alpha\beta \geq 1$, the last step follows by $\gamma \geq 1$.

Thus, we complete the proof. □

18.5 Proof of Lemma 18.3.3

Lemma 18.3.3. (Reducing the problem size by sketching on one side)**.** Given three matrices $L \in \mathbb{R}^{d_1 \times l_1}$, $M^\top \in \mathbb{R}^{d_2 \times l_2}$, $N \in \mathbb{R}^{d_1 \times d_2}$ and $\alpha \geq 1, \beta \geq 1, \gamma \geq 1, \lambda > 0$. Let $\mathrm{OPT} = \min_{X,Y} \|LXYM - N\|_1 + \lambda(\|LX\|_1 + \|YM\|_1)$. Let X^*, Y^* denote the optimal solution of

$$\min_{X,Y} \|LXYM - N\|_1 + \lambda(\|LX\|_1 + \|YM\|_1).$$

Let $T \in \mathbb{R}^{t \times d_1}$ satisfy :

$$\|TLx\|_1 \geq \frac{1}{\alpha}\|Lx\|_1, \text{ for all } x \in \mathbb{R}^{l_1}$$

and

$$\begin{aligned} & \|TLX^*Y^*M - TN\|_1 + \lambda \cdot \|TLX^*\|_1 \\ \leq & \beta(\|LX^*Y^*M - N\|_1 + \lambda \cdot \|LX^*\|_1) \end{aligned}$$

Let $\widehat{X}, \widehat{Y}$ satisfy

$$\begin{aligned} & \|TL\widehat{X}\widehat{Y}M - TN\|_1 + \lambda \cdot (\|TL\widehat{X}\|_1 + \|\widehat{Y}M\|_1) \\ \leq & \gamma \min_{X,Y} \|TLXYM - TN\|_1 + \lambda \cdot (\|TLX\|_1 + \|YM\|_1) \end{aligned}$$

Then

$$\begin{aligned} & \|L\widehat{X}\widehat{Y}M - N\|_1 + \lambda(\|L\widehat{X}\|_1 + \|\widehat{Y}M\|_1) \\ \leq & (\alpha\beta\gamma + \alpha\beta + 1)\,\mathrm{OPT}\,. \end{aligned}$$

Proof.

$$
\begin{aligned}
&\|L\widehat{X}\widehat{Y}M - N\|_1 + \lambda(\|L\widehat{X}\|_1 + \|\widehat{Y}M\|_1) \\
\leq\ & \|L(\widehat{X}\widehat{Y} - X^*Y^*)M\|_1 + \|LX^*Y^*M - N\|_1 + \lambda(\|L\widehat{X}\|_1 + \|\widehat{Y}M\|_1) \\
\leq\ & \|L(\widehat{X}\widehat{Y} - X^*Y^*)M\|_1 + \mathrm{OPT} + \lambda(\|L\widehat{X}\|_1 + \|\widehat{Y}M\|_1) \\
\leq\ & \alpha\|TL(\widehat{X}\widehat{Y} - X^*Y^*)M\|_1 + \mathrm{OPT} + \lambda(\alpha\|TL\widehat{X}\|_1 + \|\widehat{Y}M\|_1) \\
\leq\ & \alpha\|TL\widehat{X}\widehat{Y}M - TN\|_1 + \alpha\|TLX^*Y^*M - TN\|_1 + \lambda(\alpha\|TL\widehat{X}\|_1 + \|\widehat{Y}M\|_1) + \mathrm{OPT} \\
\leq\ & \alpha(\|TL\widehat{X}\widehat{Y}M - TN\|_1 + \lambda(\|TL\widehat{X}\|_1 + \|\widehat{Y}M\|_1)) + \alpha\|TLX^*Y^*M - TN\|_1 + \mathrm{OPT} \\
\leq\ & \alpha\gamma(\|TLX^*Y^*M - TN\|_1 + \lambda(\|TLX^*\|_1 + \|Y^*M\|_1)) + \alpha\|TLX^*Y^*M - TN\|_1 + \mathrm{OPT} \\
\leq\ & \alpha\beta\gamma\,\mathrm{OPT} + \alpha\|TLX^*Y^*M - TN\|_1 + \mathrm{OPT} \\
\leq\ & \alpha\beta\gamma\,\mathrm{OPT} + \alpha\beta\|LX^*Y^*M - N\|_1 + \mathrm{OPT} \\
=\ & (\alpha\beta\gamma + \alpha\beta + 1)\,\mathrm{OPT},
\end{aligned}
$$

where the first step follows by triangle inequality, the second step follows by $\|LX^*Y^*M - N\|_1 \leq \mathrm{OPT}$, the third step follows by the property of T, the forth step follows by triangle inequality, the fifth step follows by $\alpha \geq 1$, the sixth step follows by the definition of $\widehat{X}, \widehat{Y}$, the seventh step follows by the property of T, the eighth step follows by the property of T. □

18.6 Proof of Theorem 18.3.7

Proof. We choose all the matrices $S \in \mathbb{R}^{s\times n}, R \in \mathbb{R}^{n\times r}, T_1 \in \mathbb{R}^{t_1\times n}, T_2 \in \mathbb{R}^{n\times t_2}$ in Algorithm 18.1 as sparse Cauchy transformation matrices (see Definition 18.2.2) which have the same scalar $\sigma = 1$. We set $s = O(k^5 \log^5 k), r = O(k^5 \log^5 k), t_1 = O(r^5 \log^5 r), t_2 = O(s^5 \log^5 s)$.

Since computing $T_1 A, AT_2$ can be done in $\mathrm{nnz}(A)$ time, and the size of $T_1 A, AT_2$ is at most $n \cdot \mathrm{poly}(k)$, the total running time of computing $T_1 AR, SAT_2, T_1 AT_2$ is at most $\mathrm{nnz}(A) + n \cdot \mathrm{poly}(k)$. Since the size of the final small Frobenius norm ridge low-rank matrix approximation problem is $\mathrm{poly}(k)$, the running time of the whole algorithm is at most $\mathrm{nnz}(A) + n \cdot \mathrm{poly}(k)$.

Now let us consider the correctness of the algorithm.

Let $U^* \in \mathbb{R}^{n\times k}, V^* \in \mathbb{R}^{k\times n}$ satisfy $\|U^*V^* - A\|_1 + \lambda(\|U^*\|_1 + \|V^*\|_1) = \mathrm{OPT}$. Then due to Lemma 18.2.3, with probability at least 0.99, S satisfies

$$\|SU^*x\|_1 \geq \frac{1}{\alpha_1}\|U^*x\|_1 \text{ for all } x \in \mathbb{R}^k \text{ and } \|SU^*V^* - SA\|_1 \leq \beta_1\|U^*V^* - A\|_1$$

where $\alpha_1\beta_1 = O(k^2 \log^2 k \log n)$. Let $\widehat{V} \in \mathbb{R}^{k\times n}$ denote $\begin{bmatrix} SU^* \\ \lambda I \end{bmatrix}^\dagger \cdot \begin{bmatrix} I \\ 0 \end{bmatrix} \cdot SA$. Let $\widetilde{U} \in \mathbb{R}^{n\times k}$ denote the optimal solution of

$$\min_{U\in\mathbb{R}^{n\times k}} \|U\widehat{V} - A\|_1 + \lambda(\|U\|_1 + \|\widehat{V}\|_1).$$

Due to Lemma 18.2.3, with probability at least 0.99, $R^\top \in \mathbb{R}^{r\times n}$ satisfies:

$$\|R^\top\widehat{V}^\top x\|_1 \geq \frac{1}{\alpha_2}\|\widehat{V}^\top x\|_1 \text{ for all } x \in \mathbb{R}^k, \text{ and}$$
$$\|R^\top\widehat{V}^\top\widetilde{U}^\top - R^\top A^\top\|_1 \leq \beta_2\|\widehat{V}^\top\widetilde{U}^\top - A^\top\|_1$$

where $\alpha_2\beta_2 = O(k^2 \log^2 k \log n)$. Then, by applying Corollary 18.3.2, we have that

$$\min_{X\in\mathbb{R}^{r\times k}, Y\in\mathbb{R}^{k\times s}} \|ARXYSA - A\|_1 + \lambda(\|ARX\|_1 + \|YSA\|_1) \leq \mathrm{poly}(k, \log n)\,\mathrm{OPT}\,.$$

Let $X^* \in \mathbb{R}^{r\times k}, Y^* \in \mathbb{R}^{k\times s}$ denote the optimal solution of

$$\min_{X,Y} \|ARXYSA - A\|_1 + \lambda(\|ARX\|_1 + \|YSA\|_1).$$

Due to Lemma 18.2.3, with probability at least 0.99, T_1 satisfies that $\forall x \in \mathbb{R}^r, \|T_1 ARx\|_1 \geq \frac{1}{\alpha_1'}\|ARx\|_1$, and $\|T_1\left(\begin{bmatrix} ARX^*Y^*SA - A & \lambda ARX^* \end{bmatrix}\right)\|_1 \leq \beta_1' \|\begin{bmatrix} ARX^*Y^*SA - A & \lambda ARX^* \end{bmatrix}\|_1$ where $\alpha_1'\beta_1' = O(r^2 \log^2 r \log n)$. Due to Lemma 18.2.3, with probability at least 0.99, T_2 satisfies that $\forall x \in \mathbb{R}^s, \|T_2^\top A^\top S^\top x\|_1 \geq \frac{1}{\alpha_2'}\|A^\top S^\top x\|_1$ and

$$\begin{aligned}
&\|T_2^\top \left(\begin{bmatrix} A^\top S^\top (Y^*)^\top (X^*)^\top R^\top A^\top T_1^\top - A^\top T_1^\top & \lambda A^\top S^\top (Y^*)^\top \end{bmatrix}\right)\|_1 \\
\leq\ & \beta_2' \|\begin{bmatrix} A^\top S^\top (Y^*)^\top (X^*)^\top R^\top A^\top T_1^\top - A^\top T_1^\top & \lambda A^\top S^\top (Y^*)^\top \end{bmatrix}\|_1
\end{aligned}$$

where $\alpha_2'\beta_2' \leq O(s^2 \log^2 s \log n)$. Thus, by Corollary 18.3.4, for any $\gamma \geq 1$, if $\widetilde{X}, \widetilde{Y}$ can achieve

$$\begin{aligned}
&\|T_1 AR\widetilde{X}\widetilde{Y}SAT_2 - T_1AT_2\|_1 + \lambda(\|T_1AR\widetilde{X}\|_1 + \|\widetilde{Y}SAT_2\|_1) \\
\leq\ & \gamma \min_{X,Y} \left(\|T_1ARXYSAT_2 - T_1AT_2\|_1 + \lambda(\|T_1ARX\|_1 + \|YSAT_2\|_1)\right),
\end{aligned}$$

then

$$\begin{aligned}
&\|AR\widetilde{X}\widetilde{Y}SA - A\|_1 + \lambda(\|AR\widetilde{X}\|_1 + \|\widetilde{Y}SA\|_1) \\
\leq\ & \mathrm{poly}(k, \log n)\gamma \min_{X,Y} \left(\|ARXYSA - A\|_1 + \lambda(\|ARX\|_1 + \|YSA\|_1)\right).
\end{aligned}$$

Finally, due to Lemma 18.3.6, we can find such $\widetilde{X}\widetilde{Y}$ with $\gamma = O(\sqrt{t_1 + k}\sqrt{t_2 + k})$. Thus, we can conclude that $\|AR\widetilde{X}\widetilde{Y}SA - A\|_1 + \lambda(\|AR\widetilde{X}\|_1 + \|\widetilde{Y}SA\|_1) \leq \mathrm{poly}(k, \log n)\cdot\mathrm{OPT}\,.$

By taking union bound over all the success event of S, R, T_1, T_2, the algorithm will succeed with probability at least 9/10. □

18.7 Proof of Theorem 18.3.8

Proof. We choose all the matrices $S \in \mathbb{R}^{s\times n}, R \in \mathbb{R}^{n\times r}, T_1 \in \mathbb{R}^{t_1\times n}, T_2 \in \mathbb{R}^{n\times t_2}$ in Algorithm 18.1 as dense Cauchy transformation matrices (see Definition 18.2.1) which have the same scalar $\sigma = 1$. We set $s = O(k\log k), r = O(k\log k), t_1 = O(r\log r), t_2 = O(s\log s)$.

Since computing T_1A, AT_2 can be done in $t_1\,\mathrm{nnz}(A), t_2\,\mathrm{nnz}(A)$ time respectiviely, and the size of T_1A, AT_2 is at most $n\cdot\mathrm{poly}(k)$, the total running time of computing

$$T_1AR, SAT_2, T_1AT_2$$

is at most $\widetilde{O}(k)\cdot\mathrm{nnz}(A) + n\cdot\mathrm{poly}(k)$. Since the size of the final small Frobenius norm ridge low-rank matrix approximation problem is $\mathrm{poly}(k)$, the running time of the whole algorithm is at most $\widetilde{O}(k)\cdot\mathrm{nnz}(A) + n\cdot\mathrm{poly}(k)$.

Now let us consider the correctness of the algorithm.

Let $U^* \in \mathbb{R}^{n\times k}, V^* \in \mathbb{R}^{k\times n}$ satisfy $\|U^*V^* - A\|_1 + \lambda(\|U^*\|_1 + \|V^*\|_1) = \mathrm{OPT}$. Then due to Lemma 18.2.3, with probability at least 0.99, S satisfies

$$\|SU^*x\|_1 \geq \frac{1}{\alpha_1}\|U^*x\|_1 \text{ for all } x\in\mathbb{R}^k \text{ and } \|SU^*V^* - SA\|_1 \leq \beta_1\|U^*V^* - A\|_1$$

where $\alpha_1\beta_1 = O(\log n)$. Let $\widehat{V} \in \mathbb{R}^{k\times n}$ denote $\begin{bmatrix} SU^* \\ \lambda I \end{bmatrix}^\dagger \cdot \begin{bmatrix} I \\ 0 \end{bmatrix} \cdot SA$. Let $\widetilde{U} \in \mathbb{R}^{n\times k}$ denote the optimal solution of $\min_{U\in\mathbb{R}^{n\times k}} \|U\widehat{V} - A\|_1 + \lambda(\|U\|_1 + \|\widehat{V}\|_1)$. Due to Lemma 18.2.3, with probability at least 0.99, $R^\top \in \mathbb{R}^{r\times n}$ satisfies: $\|R^\top\widehat{V}^\top x\|_1 \geq \frac{1}{\alpha_2}\|\widehat{V}^\top x\|_1$ for all $x \in \mathbb{R}^k$, and $\|R^\top\widehat{V}^\top\widetilde{U}^\top - R^\top A^\top\|_1 \leq \beta_2\|\widehat{V}^\top\widetilde{U}^\top - A^\top\|_1$ where $\alpha_2\beta_2 = O(\log n)$. Then, by applying Corollary 18.3.2, we have that

$$\min_{X\in\mathbb{R}^{r\times k}, Y\in\mathbb{R}^{k\times s}} \|ARXYSA - A\|_1 + \lambda(\|ARX\|_1 + \|YSA\|_1) \leq \widetilde{O}(k)\,\mathrm{poly}(\log n)\,\mathrm{OPT}.$$

Let $X^* \in \mathbb{R}^{r\times k}, Y^* \in \mathbb{R}^{k\times s}$ denote the optimal solution of $\min_{X,Y} \|ARXYSA - A\|_1 + \lambda(\|ARX\|_1 + \|YSA\|_1)$. Due to Lemma 18.2.3, with probability at least 0.99, T_1 satisfies that $\forall x \in \mathbb{R}^r, \|T_1 ARx\|_1 \geq \frac{1}{\alpha_1'}\|ARx\|_1$, and $\|T_1 \left(\begin{bmatrix} ARX^*Y^*SA - A & \lambda ARX^* \end{bmatrix}\right)\|_1 \leq \beta_1' \| \begin{bmatrix} ARX^*Y^*SA - A & \lambda ARX^* \end{bmatrix} \|_1$ where $\alpha_1'\beta_1' = O(\log n)$. Due to Lemma 18.2.3, with probability at least 0.99, T_2 satisfies that

$$\forall x \in \mathbb{R}^s, \|T_2^\top A^\top S^\top x\|_1 \geq \frac{1}{\alpha_2'}\|A^\top S^\top x\|_1$$

and

$$\begin{aligned}
&\|T_2^\top \left(\begin{bmatrix} A^\top S^\top (Y^*)^\top (X^*)^\top R^\top A^\top T_1^\top - A^\top T_1^\top & \lambda A^\top S^\top (Y^*)^\top \end{bmatrix}\right)\|_1 \\
\leq\ & \beta_2' \| \begin{bmatrix} A^\top S^\top (Y^*)^\top (X^*)^\top R^\top A^\top T_1^\top - A^\top T_1^\top & \lambda A^\top S^\top (Y^*)^\top \end{bmatrix} \|_1
\end{aligned}$$

where $\alpha_2'\beta_2' \leq O(\log n)$. Thus, by Corollary 18.3.4, for any $\gamma \geq 1$, if $\widetilde{X}, \widetilde{Y}$ can achieve

$$\begin{aligned}
&\|T_1 AR\widetilde{X}\widetilde{Y}SAT_2 - T_1AT_2\|_1 + \lambda(\|T_1AR\widetilde{X}\|_1 + \|\widetilde{Y}SAT_2\|_1) \\
\leq\ & \gamma \min_{X,Y} \left(\|T_1ARXYSAT_2 - T_1AT_2\|_1 + \lambda(\|T_1ARX\|_1 + \|YSAT_2\|_1)\right),
\end{aligned}$$

then

$$\begin{aligned}
&\|AR\widetilde{X}\widetilde{Y}SA - A\|_1 + \lambda(\|AR\widetilde{X}\|_1 + \|\widetilde{Y}SA\|_1) \\
\leq\ & \widetilde{O}(k) \cdot \mathrm{poly}(\log n)\gamma \min_{X,Y} \left(\|ARXYSA - A\|_1 + \lambda(\|ARX\|_1 + \|YSA\|_1)\right).
\end{aligned}$$

Finally, due to Lemma 18.3.6, we can find such $\widetilde{X}\widetilde{Y}$ with $\gamma = O(\sqrt{t_1 + k}\sqrt{t_2 + k})$. Thus, we can conclude that

$$\|AR\widetilde{X}\widetilde{Y}SA - A\|_1 + \lambda(\|AR\widetilde{X}\|_1 + \|\widetilde{Y}SA\|_1) \leq \widetilde{O}(k^2)\,\mathrm{poly}(\log n) \cdot \mathrm{OPT}\,.$$

By taking union bound over all the success event of S, R, T_1, T_2, the algorithm will succeed with probability at least 9/10. □

Chapter 19

Average Case L1 Low Rank Approximation

We study the column subset selection problem with respect to the entrywise ℓ_1-norm loss. It is known that in the worst case, to obtain a good rank-k approximation to a matrix, one needs an arbitrarily large $n^{\Omega(1)}$ number of columns to obtain a $(1+\epsilon)$-approximation to the best entrywise ℓ_1-norm low rank approximation of an $n \times n$ matrix. Nevertheless, we show that under certain minimal and realistic distributional settings, it is possible to obtain a $(1+\epsilon)$-approximation with a nearly linear running time and $\text{poly}(k/\epsilon) + O(k \log n)$ columns. Namely, we show that if the input matrix A has the form $A = B + E$, where B is an arbitrary rank-k matrix, and E is a matrix with i.i.d. entries drawn from any distribution μ for which the $(1+\gamma)$-th moment exists, for an arbitrarily small constant $\gamma > 0$, then it is possible to obtain a $(1+\epsilon)$-approximate column subset selection to the entrywise ℓ_1-norm in nearly linear time. Conversely we show that if the first moment does not exist, then it is not possible to obtain a $(1+\epsilon)$-approximate subset selection algorithm even if one chooses any $n^{o(1)}$ columns. This is the first algorithm of any kind for achieving a $(1+\epsilon)$-approximation for entrywise ℓ_1-norm loss low rank approximation.

19.1 Introduction

Numerical linear algebra algorithms are fundamental building blocks in many machine learning and data mining tasks. A well-studied problem is low rank matrix approximation. The most common version of the problem is also known as Principal Component Analysis (PCA), in which the goal is to find a low rank matrix to approximate a given matrix such that the Frobenius norm of the error is minimized. The optimal solution of this objective can be obtained via the singular value decomposition (SVD). Hence, the problem can be solved in polynomial time. If approximate solutions are allowed, then the running time can be made almost linear in the number of non-zero entries of the given matrix [Sar06, CW13, MM13, NN13a, BDN15, Coh16a].

An important variant of the PCA problem is the entrywise ℓ_1-norm low rank matrix approximation problem. In this problem, instead of minimizing the Frobenius norm of the error, we seek to minimize the ℓ_1-norm of the error. In particular, given an $n \times n$ input matrix A, and a rank parameter k, we want to find a matrix B with rank at most k such that $\|A - B\|_1$ is minimized, where for a matrix C, $\|C\|_1$ is defined to be $\sum_{i,j} |C_{i,j}|$. There are several reasons for using the ℓ_1-norm as the error measure. For example, solutions with respect to the ℓ_1-norm loss are usually more robust than solutions with Frobenius norm loss [Hub64, CLMW11]. Further, the ℓ_1-norm loss is often used as a relaxation of the ℓ_0-loss, which has wide applications including sparse recovery, matrix completion, and robust PCA; see e.g., [XCS10, CLMW11]. Although a number of algorithms have been proposed for the ℓ_1-norm loss [KK03, KK05, KLC+15, Kwa08, ZLS+12, BJ12, BD13, BDB13, MXZZ13, MKP13, MKP14, MKCP16, PK16], the problem is known to be NP-hard [GV15]. The first ℓ_1-low rank approximation with provable guarantees was proposed by [SWZ17]. To cope

with NP-hardness, the authors gave a solution with a $\mathrm{poly}(k \log n)$-approximation ratio, i.e., their algorithm outputs a rank-k matrix $B' \in \mathbb{R}^{n \times n}$ for which

$$\|A - B'\|_1 \leq \alpha \cdot \min_{\mathrm{rank}-k \ B} \|A - B\|_1$$

for $\alpha = \mathrm{poly}(k \log n)$. The approximation ratio α was further improved to $O(k \log k)$ by allowing B' to have a slightly larger $k' = O(k \log n)$ rank [CGK+17a]. Such B' with larger rank is referred to as a bicriteria solution. However, in high precision applications, such approximation factors are too large. A natural question is if one can compute a $(1+\epsilon)$-approximate solution efficiently for ℓ_1-norm low rank approximation. In fact, a $(1+\epsilon)$-approximation algorithm was given in [BBB+19a], but the running time of their algorithm is a prohibitive $n^{\mathrm{poly}(k/\epsilon)}$. Unfortunately, [BBB+19a] shows in the worst case that a $2^{k^{\Omega(1)}}$ running time is necessary for any constant approximation given a standard conjecture in complexity theory.

19.1.1 Notation

To describe our results, let us first introduce some notation. We will use $[n]$ to denote the set $\{1, 2, \cdots, n\}$. We use A_i to denote the i^{th} column of A. We use A^j to denote the j^{th} row of A. Let $Q \subseteq [n]$. We use A_Q to denote the matrix which is comprised of the columns of A with column indices in Q. Similarly, we use A^Q to denote the matrix which is comprised of the rows of A with row indices in Q. We use $\binom{[n]}{t}$ to denote the set of all the size-t subsets of $[n]$. Let $\|A\|_F$ denote the Frobenius norm of a matrix A, i.e., $\|A\|_F$ is the square root of the sum of squares of all the entries in A. For $1 \leq p < 2$, we use $\|A\|_p$ to denote the entry-wise ℓ_p-norm of a matrix A, i.e., $\|A\|_p$ is the p-th root of the sum of p-th powers of the absolute values of the entries of A. $\|A\|_1$ is an important special case of $\|A\|_p$,

which corresponds to the sum of absolute values of the entries in A. A random variable X has the Cauchy distribution if its probability density function is $f(z) = \frac{1}{\pi(1+z^2)}$.

19.1.2 Our Results

We propose an efficient bicriteria $(1+\epsilon)$-approximate column subset selection algorithm for the ℓ_1-norm. We bypass the running time lower bound mentioned above by making a mild assumption on the input data, and also show that our assumption is necessary in a certain sense.

Our main algorithmic result is described as follows.

Theorem 19.1.1 (Informal version of Theorem 19.2.9)**.** *Suppose we are given a matrix $A = A^* + \Delta \in \mathbb{R}^{n\times n}$, where $\mathrm{rank}(A^*) = k$ for $k = n^{o(1)}$, and Δ is a random matrix for which the $\Delta_{i,j}$ are i.i.d. symmetric random variables with $\mathbb{E}[|\Delta_{i,j}|^p] = O(\mathbb{E}[|\Delta_{i,j}|]^p)$ for some constant $p > 1$. Let $\epsilon \in (0, 1/2)$ satisfy $1/\epsilon = n^{o(1)}$. There is an $\widetilde{O}(n^2 + n\,\mathrm{poly}(k/\epsilon))$[1] time algorithm (Algorithm 19.1) which can output a subset $S \subseteq [n]$ with $|S| \leq \mathrm{poly}(k/\epsilon) + O(k \log n)$ for which*

$$\min_{X\in\mathbb{R}^{|S|\times n}} \|A_S X - A\|_1 \leq (1+\epsilon)\|\Delta\|_1,$$

holds with probability at least 99/100.

Note the running time in Theorem 19.1.1 is nearly linear in the number of non-zero entries of A, since for an $n \times n$ matrix with i.i.d. noise drawn from any continuous distribution, the number of non-zero entries of A will be n^2 with probability 1. We also show the moment assumption of Theorem 19.1.1 is necessary in the following precise sense.

[1] We use the notation $\widetilde{O}(f) := O(f \cdot \log^{O(1)} f)$.

Theorem 19.1.2 (Hardness, informal version of Theorem 19.4.17)**.** *Let $n > 0$ be sufficiently large. Let $A = \eta \cdot \mathbf{1} \cdot \mathbf{1}^\top + \Delta \in \mathbb{R}^{n \times n}$ be a random matrix where $\eta = n^{c_0}$ for some sufficiently large constant c_0, $\mathbf{1} \in \mathbb{R}^n$ is the all-ones vector, and $\forall i, j \in [n], \Delta_{i,j} \sim C(0,1)$ are i.i.d. standard Cauchy random variables. Let $r = n^{o(1)}$. Then with probability at least $1 - O(1/\log\log n)$, $\forall S \subseteq [n]$ with $|S| = r$,*

$$\min_{X \in \mathbb{R}^{r \times n}} \|A_S X - A\|_1 \geq 1.002 \|\Delta\|_1.$$

19.1.3 Our Techniques

For an overview of our hardness result, we refer readers to the supplementary material, namely, Appendix 19.4. In the following, we will outline the main techniques used in our algorithm.

$(1+\epsilon)$-Approximate ℓ_1-Low Rank Approximation. We make the following distributional assumption on the input matrix $A \in \mathbb{R}^{n \times n}$: namely, $A = A^* + \Delta$ where A^* is an arbitrary rank-k matrix and the entries of Δ are i.i.d. from any symmetric distribution with $\mathbb{E}[|\Delta_{i,j}|] = 1$ and $\mathbb{E}[|\Delta_{i,j}|^p] = O(1)$ for any real number p strictly greater than 1, e.g., $p = 1.000001$ would suffice. Note that such an assumption is mild compared to typical noise models which require the noise be Gaussian or have bounded variance; in our case the random variables may even be heavy-tailed with infinite variance. In this setting we show it is possible to obtain a subset of $\text{poly}(k(\epsilon^{-1} + \log n))$ columns spanning a $(1+\epsilon)$-approximation. This provably overcomes the column subset selection lower bound of [SWZ17] which shows for entrywise ℓ_1-low rank approximation that there are matrices for which any subset of $\text{poly}(k)$ columns spans at best a $k^{\Omega(1)}$-approximation.

Consider the following algorithm: sample $\text{poly}(k/\epsilon)$ columns of A, and try to cover as many of the remaining columns as possible. Here, by covering a column i, we mean that if A_I is the subset of columns sampled, then $\min_y \|A_I y - A_i\|_1 \leq (1+O(\epsilon))n$. The reason for this notion of covering is that we are able to show in Lemma 19.2.1 that in this noise model, $\|\Delta\|_1 \geq (1-\epsilon)n^2$ w.h.p., and so if we could cover every column i, our overall cost would be $(1+O(\epsilon))n^2$, which would give a $(1+O(\epsilon))$-approximation to the overall cost.

We will not be able to cover all columns, unfortunately, with our initial sample of $\text{poly}(k/\epsilon)$ columns of A. Instead, though, we will show that we will be able to cover all but a set T of $\epsilon n/(k \log k)$ of the columns. Fortunately, we show in Lemma 19.2.4 another property of the noise matrix Δ is that *all* subsets S of columns of size at most n/r, for $r \geq (1/\gamma)^{1+1/(p-1)}$ satisfy $\sum_{j \in S} \|\Delta_j\|_1 = O(\gamma n^2)$. Thus, for the above set T that we do not cover, we can apply this lemma to it with $\gamma = \epsilon/(k \log k)$, and then we know that $\sum_{j \in T} \|\Delta_j\|_1 = O(\epsilon n^2/(k \log k))$, which then enables us to run a previous $\widetilde{O}(k)$-approximate ℓ_1 low rank approximation algorithm [CGK+17a] on the set T, which will only incur total cost $O(\epsilon n^2)$, and since by Lemma 19.2.1 above the overall cost is at least $(1-\epsilon)n^2$, we can still obtain a $(1+O(\epsilon))$-approximation overall.

The main missing piece of the algorithm to describe is why we are able to cover all but a small fraction of the columns. One thing to note is that our noise distribution may not have a finite variance, and consequently, there *can* be very large entries $\Delta_{i,j}$ in some columns. In Lemma 19.2.3, we show the number of columns in Δ for which there exists an entry larger than $n^{1/2+1/(2p)}$ in magnitude is $O(n^{(2-p)/2})$, which since $p > 1$ is a constant bounded away from 1, is sublinear. Let us call this set with entries larger than $n^{1/2+1/(2p)}$ in magnitude the set H of "heavy" columns; we will not make any guarantees about H,

rather, we will stuff it into the small set T of columns above on which we will run our earlier $O(k \log k)$-approximation.

For the remaining, non-heavy columns, which constitute almost all of our columns, we show in Lemma 19.2.5 that $\|\Delta_i\|_1 \leq (1+\epsilon)n$ w.h.p. The reason this is important is that recall to cover some column i by a sample set I of columns, we need $\min_y \|A_I y - A_i\|_1 \leq (1+O(\epsilon))n$. It turns out, as we now explain, that we will get

$$\min_y \|A_I y - A_i\|_1 \leq \|\Delta_i\|_1 + e_i,$$

where e_i is a quantity which we can control and make $O(\epsilon n)$ by increasing our sample size I. Consequently, since $\|\Delta_i\|_1 \leq (1+\epsilon)n$, overall we will have $\min_y \|A_I y - A_i\|_1 \leq (1+O(\epsilon))n$, which means that i will be covered. We now explain what e_i is, and why $\min_y \|A_I y - A_i\|_1 \leq \|\Delta_i\|_1 + e_i$.

Towards this end, we first explain a key insight in this model. Since the p-th moment exists for some real number $p > 1$ (e.g., $p = 1.000001$ suffices), *averaging* helps reduce the noise of fitting a column A_i by subsets of other columns. Namely, we show in Lemma 19.2.2 that for any t non-heavy column $\Delta_{i_1}, \ldots, \Delta_{i_t}$ of Δ, and any coefficients $\alpha_1, \alpha_2, \ldots, \alpha_t \in [-1, 1]$, $\|\sum_{j=1}^t \alpha_j \Delta_{i_j}\|_1 = O(t^{1/p} n)$, that is, since the individual coordinates of the Δ_{i_j} are zero-mean random variables, their sum *concentrates* as we add up more columns. We do not need bounded variance for this property.

How can we use this averaging property for subset selection? The idea is, instead of sampling a single subset I of $O(k)$ columns and trying to cover each remaining column with this subset as shown in [CGK+17a], we will sample multiple independent subsets $I_1, I_2, \ldots, I_t$. By a similar argument of [CGK+17a], for any given column index $i \in [n]$, for most of these

subset I_j, we have that $A_i^*/\|\Delta_i\|_1$ can be expressed as a linear combination of columns $A_\ell^*/\|\Delta_\ell\|_1, \ell \in I_j$, via coefficients of absolute value at most 1. Note that this is only true for most i and most j; we develop terminology for this in Definitions 19.2.1, 19.2.2, 19.2.3, and 19.2.4, referring to what we call a *good core*. We quantify what we mean by most i and most j having this property in Lemma 19.2.7 and Lemma 19.2.8.

The key though, that drives the analysis, is Lemma 19.2.6, which shows that $\min_y \|A_i y - A_i\|_1 \leq \|\Delta_i\|_1 + e_i$, where $e_i = O(q^{1/p}/t^{1-1/p}n)$, where q is the size of each I_j, and t is the number of different I_j. We need q to be at least k, just as before, so that we can be guaranteed that when we adjoin a column index i to I_j, there is some positive probability that $A_i^*/\|\Delta_i\|_1$ can be expressed as a linear combination of columns $A_\ell^*/\|\Delta_\ell\|_1, \ell \in I_j$, with coefficients of absolute value at most 1. What is different in our noise model though is the division by $t^{1-1/p}$. Since $p > 1$, if we set t to be a large enough poly(k/ϵ), then $e_i = O(\epsilon n)$, and then we will have covered A_i, as desired. This captures the main property that averaging the linear combinations for expression $A_i^*/\|\Delta_i\|_1$ using different subsets I_j gives us better and better approximations to $A_i^*/\|\Delta_i\|_1$. Of course we need to ensure several properties such as not sampling a heavy column (the averaging in Lemma 19.2.2 does not apply when this happens), we need to ensure most of the I_j have small-coefficient linear combinations expressing $A_i^*/\|\Delta_i\|_1$, etc. This is handled in our main theorem, Theorem 19.2.9.

19.2 ℓ_1-Norm Column Subset Selection

We first present two subroutines.

Linear regression with ℓ_1 loss. The first subroutine needed is an approximate ℓ_1 linear regression solver. In particular, given a matrix $M \in \mathbb{R}^{n\times d}$, n vectors $b_1, b_2, \cdots, b_n \in \mathbb{R}^n$, and an error parameter $\epsilon \in (0,1)$, we want to compute $x_1, x_2, \cdots, x_n \in \mathbb{R}^d$ for which $\forall i \in [n]$, we have

$$\|Mx_i - b_i\|_1 \leq (1+\epsilon) \cdot \min_{x\in\mathbb{R}^d} \|Mx - b_i\|_1.$$

Furthermore, we also need an estimate v_i of the regression cost $\|Mx_i - b_i\|_1$ for each $i \in [n]$ such that $\|Mx_i - b_i\|_1 \leq v_i \leq (1+\epsilon)\|Mx_i - b_i\|_1$. Such an ℓ_1-regression problem can be solved efficiently (see [Woo14b] for a survey). The total running time to solve these n regression problems simultaneously is at most $\widetilde{O}(n^2) + n \cdot \mathrm{poly}(d \log n)$, and the success probability is at least 0.999.

ℓ_1 Column subset selection for general matrices. The second subroutine needed is an ℓ_1-low rank approximation solver for general input matrices, though we allow a large approximation ratio. We use the algorithm proposed by [CGK+17a] for this purpose. In particular, given an $n \times d$ ($d \leq n$) matrix M and a rank parameter k, the algorithm can output a small set $S \subset [n]$ with size at most $O(k \log n)$, such that

$$\min_{X\in\mathbb{R}^{|S|\times d}} \|M_S X - M\|_1 \leq O(k \log k) \cdot \min_{\mathrm{rank}-k\ B} \|M - B\|_1.$$

Furthermore, the running time is at most $\widetilde{O}(n^2) + n \cdot \mathrm{poly}(k \log n)$, and the success probability is at least 0.999. Now we can present our algorithm, Algorithm 19.1.

Algorithm 19.1 ℓ_1-Low Rank Approximation with Input Assumption

procedure L1NoisyLowRankApprox($A \in \mathbb{R}^{n\times n}, k, \epsilon$) ▷ Theorem 19.2.9
  Sample a set I from $\binom{[n]}{s}$ uniformly at random, where $s = \mathrm{poly}(k/\epsilon)$.
  Solve the approximate ℓ_1-regression problem $\min_{x\in\mathbb{R}^{|I|}} \|A_I x - A_i\|_1$ for each $i \in [n]$, and let v_i be the estimated regression cost.
  Compute the set $T = \{i \in [n] \mid v_i$ is one of the top l largest values among $v_1, v_2, \cdots, v_n\}$, where $l = n/\mathrm{poly}(k/\epsilon)$.
  Solve ℓ_1-column subset selection for A_T. Let the solution be A_Q.
  Solve the approximate ℓ_1-regression problem $\min_{X\in\mathbb{R}^{(|I|+|Q|)\times n}} \|A_{(I\cup S)}X - A\|_1$, and let $\widehat{X}$ be the solution. Return $A_{(I\cup S)}$ and $\widehat{X}$. ▷ $A_{(I\cup S)}\widehat{X}$ is a good low rank approximation to A
end procedure

Running time. Uniformly sampling a set I can be done in $\mathrm{poly}(k/\epsilon)$ time. According to our ℓ_1-regression subroutine, solving $\min_x \|A_I x - A_i\|_1$ for all $i \in [n]$ can be finished in $\widetilde{O}(n^2) + n \cdot \mathrm{poly}(k\log(n)/\epsilon)$ time. We only need sorting to compute the set T which takes $O(n \log n)$ time. By our second subroutine, the ℓ_1-column subset selection for A_T will take $\widetilde{O}(n^2) + n \cdot \mathrm{poly}(k \log n)$. The last step only needs an ℓ_1-regression solver, which takes $\widetilde{O}(n^2)+n\cdot\mathrm{poly}(k\log(n)/\epsilon)$ time. Thus, the overall running time is $\widetilde{O}(n^2)+n\cdot\mathrm{poly}(k\log(n)/\epsilon)$.

The remaining parts in this section will focus on analyzing the correctness of the algorithm.

19.2.1 Properties of the Noise Matrix

Recall that the input matrix $A \in \mathbb{R}^{n\times n}$ can be decomposed as $A^* + \Delta$, where A^* is the ground truth, and Δ is a random noise matrix. In particular, A^* is an arbitrary rank-k matrix, and Δ is a random matrix where each entry is an i.i.d. sample drawn from an unknown symmetric distribution. The only assumption on Δ is that each entry $\Delta_{i,j}$

satisfies $\mathbb{E}[|\Delta_{i,j}|^p] = O(\mathbb{E}[|\Delta_{i,j}|^p])$ for some constant $p > 1$, i.e., the p-th moment of the noise distribution is bounded. Without loss of generality, we will suppose $\mathbb{E}[|\Delta_{i,j}|] = 1$, $\mathbb{E}[|\Delta_{i,j}|^p] = O(1)$, and $p \in (1, 2)$ throughout the paper. In this section, we will present some key properties of the noise matrix.

The following lemma provides a lower bound on $\|\Delta\|_1$. Once we have the such lower bound, we can focus on finding a solution for which the approximation cost is at most that lower bound.

Lemma 19.2.1 (Lower bound on the noise matrix)**.** *Let $\Delta \in \mathbb{R}^{n \times n}$ be a random matrix where $\Delta_{i,j}$ are i.i.d. samples drawn from a symmetric distribution. Suppose $\mathbb{E}[|\Delta_{i,j}|] = 1$ and $\mathbb{E}[|\Delta_{i,j}|^p] = O(1)$ for some constant $p \in (1, 2)$. Then, $\forall \epsilon \in (0, 1)$ which satisfies $1/\epsilon = n^{o(1)}$, we have*

$$\Pr\left[\|\Delta\|_1 \geq (1 - \epsilon)n^2\right] \geq 1 - e^{-\Theta(n)}.$$

The next lemma shows the main reason why we are able to get a small fitting cost when running regression. Consider a toy example. Suppose we have a target number $a \in \mathbb{R}$, and another t numbers $a + g_1, a + g_2, \cdots, a + g_t \in \mathbb{R}$, where g_i are i.i.d. samples drawn from the standard Gaussian distribution $N(0, 1)$. If we use $a + g_i$ to fit a, then the expected cost is $\mathbb{E}[|a + g_i - a|] = \mathbb{E}[|g_i|] = \sqrt{2/\pi}$. However, if we use the average of $a + g_1, a + g_2, \cdots, a + g_t$ to fit a, then the expected cost is $\mathbb{E}[|\sum_{i=1}^t g_i|/t]$. Since the g_i are independent, $\sum_{i=1}^t g_i$ is a random Gaussian variable with variance t, which means that the above expected cost is $\sqrt{2/\pi}/\sqrt{t}$. Thus the fitting cost is reduced by a factor $\sqrt{t}$. By generalizing the above argument, we obtain the following lemma.

Lemma 19.2.2 (Averaging reduces the noise)**.** *Let $\Delta_1, \Delta_2, \cdots, \Delta_t \in \mathbb{R}^n$ be t random vectors. The $\Delta_{i,j}$ are i.i.d. symmetric random variables with $\mathbb{E}[|\Delta_{i,j}|] = 1$ and $\mathbb{E}[|\Delta_{i,j}|^p] = O(1)$ for some constant $p \in (1,2)$. Let $\alpha_1, \alpha_2, \cdots, \alpha_t \in [-1,1]$ be t real numbers. Conditioned on $\forall i \in [n], j \in [t], |\Delta_{i,j}| \leq n^{1/2+1/(2p)}$, with probability at least $1 - 2^{-n^{\Theta(1)}}$,*

$$\left\| \sum_{i=1}^{t} \alpha_i \Delta_i \right\|_1 \leq O(t^{1/p} n).$$

The above lemma needs a condition that each entry in the noise column should not be too large. Fortunately, we can show that most of the (noise) columns do not have any large entry.

Lemma 19.2.3 (Only a small number of columns have large entries)**.** *Let $\Delta \in \mathbb{R}^{n \times n}$ be a random matrix where the $\Delta_{i,j}$ are i.i.d. symmetric random variables with $\mathbb{E}[|\Delta_{i,j}|] = 1$ and $\mathbb{E}[|\Delta_{i,j}|^p] = O(1)$ for some constant $p \in (1,2)$. Let*

$$H = \{ j \in [n] \mid \exists i \in [n], |\Delta_{i,j}| > n^{1/2+1/(2p)} \}.$$

Then with probability at least 0.999,

$$|H| \leq O(n^{1-(p-1)/2}).$$

The following lemma shows that any small subset of the columns of the noise matrix Δ cannot contribute too much to the overall error. By combining with the previous lemma, the entrywise ℓ_1 cost of all columns containing large entries can be bounded.

Lemma 19.2.4. *Let $\Delta \in \mathbb{R}^{n \times n}$ be a random matrix where $\Delta_{i,j}$ are i.i.d. symmetric random variables with $\mathbb{E}[|\Delta_{i,j}|] = 1$ and $\mathbb{E}[|\Delta_{i,j}|^p] = O(1)$ for some constant $p \in (1,2)$. Let $\epsilon \in (0,1)$*

satisfy $1/\epsilon = n^{o(1)}$. *Let* $r \geq (1/\epsilon)^{1+1/(p-1)}$. *Then, with probability at least* .999, $\forall S \subset [n]$ *with* $|S| \leq n/r$,

$$\sum_{j \in S} \|\Delta_j\|_1 = O(\epsilon n^2).$$

We say a (noise) column is good if it does not have a large entry. We can show that, with high probability, the entry-wise ℓ_1 cost of a good (noise) column is small.

Lemma 19.2.5 (Cost of good noise columns)**.** *Let* $\Delta \in \mathbb{R}^n$ *be a random vector where* Δ_i *are i.i.d. symmetric random variables with* $\mathbb{E}[|\Delta_i|] = 1$ *and* $\mathbb{E}[|\Delta_i|^p] = O(1)$ *for some constant* $p \in (1, 2)$. *Let* $\epsilon \in (0, 1)$ *satisfy* $1/\epsilon = n^{o(1)}$. *If* $\forall i \in [n], |\Delta_i| \leq n^{1/2+1/(2p)}$, *then with probability at least* $1 - 2^{-n^{\Theta(1)}}$,

$$\|\Delta\|_1 \leq (1 + \epsilon)n.$$

19.2.2 Definition of Tuples and Cores

In this section, we provide some basic definitions, e.g., of a tuple, a good tuple, the core of a tuple, and a coefficients tuple. These definitions will be heavily used later when we analyze the correctness of our algorithm.

Before we present the definitions, we introduce a notion $R_{A^*}(S)$. Given a matrix $A^* \in \mathbb{R}^{n_1 \times n_2}$, for a set $S \subseteq [n_2]$, we define

$$R_{A^*}(S) := \arg \max_{P: P \subseteq S} \left\{ \left| \det\left((A^*)_P^Q \right) \right| \;\middle|\; |P| = |Q| = \mathrm{rank}(A^*_S), Q \subseteq [n_1] \right\},$$

where for a squared matrix C, $\det(C)$ denotes the determinant of C. Roughly speaking, by Cramer's rule, if we use the columns of A^* with index in the set $R_{A^*}(S)$ to fit any column

of A^* with index in the set S, the absolute value of any fitting coefficient will be at most 1. Small fitting coefficients are good since they will not increase the noise by too much. For example, suppose $A_i^* = A_S^* x$ and $\|x\|_\infty \leq 1$, i.e., the i-th column can be fit by the columns with indices in the set S and the fitting coefficients $x \in \mathbb{R}^{|S|}$ are small. If we use the noisy columns of $A_S^* + \Delta_S$ to fit the noisy column $A_i^* + \Delta_i$, then the fitting cost is at most

$$\|(A_S^* + \Delta_S)x - (A_i^* + \Delta_i)\|_1 \leq \|\Delta_i\|_1 + \|\Delta_S x\|_1.$$

Since $\|x\|_\infty \leq 1$, it is possible to give a good upper bound for $\|\Delta_S x\|_1$.

Definition 19.2.1 (Tuple)**.** A $(q, t, n)-$tuple is defined to be $(S_1, S_2, \cdots, S_t, i)$, where $\forall j \in [t], S_j \subset [n]$ with $|S_j| = q$. Let $S = \bigcup_{j=1}^t S_j$. Then $|S| = qt$, i.e., $S_1, S_2, \cdots, S_t$ are disjoint. Furthermore, $i \in [n]$ and $i \notin S$. For simplicity, we use $(S_{[t]}, i)$ to denote $(S_1, S_2, \cdots, S_t, i)$.

We next provide the definition of a good tuple.

Definition 19.2.2 (Good tuple)**.** Given a rank-k matrix $A^* \in \mathbb{R}^{n \times n}$, an (A^*, q, t, α)-good tuple is a (q, t, n)-tuple $(S_{[t]}, i)$ which satisfies

$$|\{j \in [t] \mid i \notin R_{A^*}(S_j \cup \{i\})\}| \geq \alpha \cdot t.$$

We need the definition of the core of a tuple.

Definition 19.2.3 (Core of a tuple)**.** The core of $(S_{[t]}, i)$ is defined to be the set

$$\{j \in [t] \mid i \notin R_{A^*}(S_j \cup \{i\})\}.$$

We define a coefficients tuple as follows.

Definition 19.2.4 (Coefficients tuple)**.** Given a rank-k matrix $A^* \in \mathbb{R}^{n\times n}$, let $(S_{[t]}, i)$ be an (A^*, q, t, α)-good tuple. Let C be the core of $(S_{[t]}, i)$. A coefficients tuple corresponding to $(S_{[t]}, i)$ is defined to be $(x_1, x_2, \cdots, x_t)$ where $\forall j \in [t], x_j \in \mathbb{R}^q$. The vector $x_j \in \mathbb{R}^q$ satisfies: $x_j = 0$ if $j \in [t]\backslash C$, while $A^*_{S_j} x_j = A^*_i$ and $\|x_j\|_\infty \leq 1$, if $j \in C$. To guarantee the coefficients tuple is unique, we restrict each vector $x_j \in \mathbb{R}^q$ to be one that has the minimum lexicographic order.

19.2.3 Properties of a Good Tuple and a Coefficients Tuple

Consider a good tuple $(S_1, S_2, \cdots, S_t, i)$. By the definition of a good tuple, the size of the core C of the tuple is large. For each $j \in C$, the coefficients x_j of using $A^*_{S_j}$ to fit A^*_i should have absolute value at most 1. Now consider the noisy setting. As discussed in the previous section, using A_{S_j} to fit A_i has cost at most $\|\Delta_i\|_1 + \|\Delta_{S_j} x_j\|_1$. Although $\|\Delta_{S_j} x_j\|_1$ has a good upper bound, it is not small enough. To further reduce the ℓ_1 fitting cost, we can now apply the averaging argument (Lemma 19.2.2) over all the fitting choices corresponding to C. Formally, we have the following lemma.

Lemma 19.2.6 (Good tuples imply low fitting cost)**.** *Suppose we are given a matrix $A \in \mathbb{R}^{n\times n}$ which satisfies $A = A^* + \Delta$, where $A^* \in \mathbb{R}^{n\times n}$ has rank k. Here $\Delta \in \mathbb{R}^{n\times n}$ is a random matrix where $\Delta_{i,j}$ are i.i.d. symmetric random variables with $\mathbb{E}[|\Delta_{i,j}|] = 1$ and $\mathbb{E}[|\Delta_{i,j}|^p] = O(1)$ for some constant $p \in (1, 2)$. Let $H \subset [n]$ be defined as follows:*

$$H = \left\{ j \in [n] \;\middle|\; \exists i \in [n], |\Delta_{i,j}| > n^{1/2+1/(2p)} \right\}.$$

Let $q, t \leq n^{o(1)}$. Then, with probability at least $1 - 2^{-n^{\Theta(1)}}$, for all $(A^*, q, t, 1/2)$-good tuples

$(S_1, S_2, \cdots, S_t, i)$ *which satisfy* $H \cap \left(\bigcup_{j=1}^{t} S_j\right) = \emptyset$, *we have*

$$\min_{y \in \mathbb{R}^{qt}} \left\| A_{\{\bigcup_{j=1}^{t} S_j\}} y - A_i \right\|_1 \leq \left\| \frac{1}{|C|} \sum_{j=1}^{t} A_{S_j} x_j - A_i \right\|_1 \leq \|\Delta_i\|_1 + O(q^{1/p}/t^{1-1/p} n),$$

where C *is the core of* $(S_1, S_2, \cdots, S_t, i)$, *and* $(x_1, x_2, \cdots, x_t)$ *is the coefficients tuple corresponding to* $(S_1, S_2, \cdots, S_t, i)$.

We next show that if we choose columns randomly, it is easy to find a good tuple.

Lemma 19.2.7. *Given a rank-k matrix* $A^* \in \mathbb{R}^{n \times n}$, *let* $q > 10k, t > 0$. *Let* $I = \{i_1, i_2, \cdots, i_{qt+1}\}$ *be a subset drawn uniformly at random from* $\binom{[n]}{qt+1}$. *Let* $\pi : I \to I$ *be a random permutation of* $qt + 1$ *elements.* $\forall j \in [t]$, *let*

$$S_j = \left\{ i_{\pi((j-1)q+1)}, i_{\pi((j-1)q+2)}, \cdots, i_{\pi((j-1)q+q)} \right\}.$$

We use i *to denote* $i_{\pi(qt+1)}$. *With probability* $\geq 1 - 2k/q$, $(S_1, S_2, \cdots, S_t, i)$ *is an* $(A^*, q, t, 1/2)-$*good tuple.*

Lemma 19.2.7 implies that if we randomly choose $S_1, S_2, \cdots, S_t$, then with high probability, there are many choices of $i \in [n]$, such that $(S_1, S_2, \cdots, S_t, i)$ is a good tuple. Precisely, we can show the following.

Lemma 19.2.8. *Given a rank-k matrix* $A^* \in \mathbb{R}^{n \times n}$, *let* $q > 10k, t > 0$. *Let* $I = \{i_1, i_2, \cdots, i_{qt}\}$ *be a random subset uniformly drawn from* $\binom{[n]}{qt}$. *Let* π *be a random permutation of* qt *elements.* $\forall j \in [t]$, *we define* S_j *as follows:*

$$S_j = \left\{ i_{\pi((j-1)q+1)}, i_{\pi((j-1)q+2)}, \cdots, i_{\pi((j-1)q+q)} \right\}.$$

Then with probability at least $2k/q$,

$$\left| \left\{ i \in [n] \setminus I \;\middle|\; (S_1, S_2, \cdots, S_t, i) \text{ is an } (A^*, q, t, 1/2)-\text{good tuple } \right\} \right| \geq (1 - 4k/q)(n - qt).$$

19.2.4 Main Result

Now we are able to put all ingredients together to prove our main theorem, Theorem 19.2.9.

Theorem 19.2.9 (Formal version of Theorem 19.1.1)**.** *Suppose we are given a matrix* $A = A^* + \Delta \in \mathbb{R}^{n\times n}$*, where* $\mathrm{rank}(A^*) = k$ *for* $k = n^{o(1)}$*, and* Δ *is a random matrix for which the* $\Delta_{i,j}$ *are i.i.d. symmetric random variables with* $\mathbb{E}[|\Delta_{i,j}|] = 1$ *and* $\mathbb{E}[|\Delta_{i,j}|^p] = O(1)$ *for some constant* $p \in (1,2)$*. Let* $\epsilon \in (0, 1/2)$ *satisfy* $1/\epsilon = n^{o(1)}$*. There is an* $\widetilde{O}(n^2 + n\,\mathrm{poly}(k/\epsilon))$ *time algorithm (Algorithm 19.1) which can output a subset* $S \in [n]$ *with* $|S| \leq \mathrm{poly}(k/\epsilon) + O(k \log n)$ *for which*

$$\min_{X\in\mathbb{R}^{|S|\times n}} \|A_S X - A\|_1 \leq (1+\epsilon)\|\Delta\|_1,$$

holds with probability at least $99/100$*.*

Proof. We discussed the running time at the beginning of Section 19.2. Next, we turn to correctness. Let

$$q = \Omega\left(\frac{k(k\log k)^{1+\frac{1}{p-1}}}{\epsilon^{1+\frac{1}{p-1}}}\right), \quad t = \frac{q^{\frac{1}{p-1}}}{\epsilon^{1+\frac{1}{p-1}}}.$$

Let $r = \Theta(q/k)$. Let

$$I_1 = \left\{i_1^{(1)}, i_2^{(1)}, \cdots, i_{qt}^{(1)}\right\}, I_2 = \left\{i_1^{(2)}, i_2^{(2)}, \cdots, i_{qt}^{(2)}\right\}, \cdots, I_r = \left\{i_1^{(r)}, i_2^{(r)}, \cdots, i_{qt}^{(r)}\right\},$$

be r independent subsets drawn uniformly at random from $\binom{[n]}{qt}$. Let $I = \bigcup_{s\in[r]} I_s$, which is the same as that in Algorithm 19.1. Let $\pi_1, \pi_2, \cdots, \pi_r$ be r independent random permutations

of qt elements. Due to Lemma 19.2.8 and a Chernoff bound, with probability at least .999, $\exists s \in [r]$,

$$\left|\left\{i \in [n] \setminus I_s \;\middle|\; (S_1, S_2, \cdots, S_t, i) \text{ is an } (A^*, q, t, 1/2)-\text{good tuple } \right\}\right| \geq (1 - 4k/q)(n - qt)$$

where

$$S_j = \left\{i^{(s)}_{\pi_s((j-1)q+1)}, i^{(s)}_{\pi_s((j-1)q+2)}, \cdots, i^{(s)}_{\pi_s((j-1)q+q)}\right\}, \forall j \in [t].$$

Let set $H \subset [n]$ be defined as follows:

$$H = \{j \in [n] \mid \exists i \in [n], |\Delta_{i,j}| > n^{1/2+1/(2p)}\}.$$

Then due to Lemma 19.2.3, with probability at least 0.999, $|H| \leq O(n^{1-(p-1)/2})$. Thus, for $j \in [r]$, the probability that $H \cap I_j \neq \emptyset$ is at most $O(qt \cdot n^{1-(p-1)/2}/(n - qt)) = 1/n^{\Omega(1)}$. By taking a union bound over all $j \in [r]$, with probability at least $1 - 1/n^{\Omega(1)}$, $\forall j \in [r], I_j \cap H = \emptyset$. Thus, we can condition on $I_s \cap H = \emptyset$. Due to Lemma 19.2.6 and $q^{1/p}/t^{1-1/p} = \epsilon$,

$$\left|\left\{i \in [n] \setminus I_s \;\middle|\; \min_{y \in \mathbb{R}^{qt}} \|A_{I_s} y - A_i\|_1 \leq \|\Delta_i\|_1 + O(\epsilon n)\right\}\right| \geq (1 - 4k/q)(n - qt).$$

Due to Lemma 19.2.5 and a union bound over all $i \in [n] \setminus H$, with probability at least .999, $\forall i \notin H, \|\Delta_i\| \leq (1 + \epsilon)n$. Thus,

$$\left|\left\{i \in [n] \setminus I_s \;\middle|\; \min_{y \in \mathbb{R}^{qt}} \|A_{I_s} y - A_i\|_1 \leq (1 + O(\epsilon))n\right\}\right| \geq (1 - 4k/q)(n - qt) - |H|.$$

Let

$$T' = [n] \setminus \left\{i \in [n] \;\middle|\; \min_{y \in \mathbb{R}^{qt}} \|A_{I_s} y - A_i\|_1 \leq (1 + O(\epsilon))n\right\}.$$

Then $|T'| \leq O(kn/q + n^{1-(p-1)/2}) = O(kn/q) = O((\epsilon/(k \log k))^{1+1/(p-1)} n)$. By our selection of T in algorithm 19.1, T' should be a subset of T. Due to Lemma 19.2.4, with probability at least .999, $\|\Delta_T\|_1 \leq O(\epsilon n^2/(k \log k))$. By our second subroutine mentioned at the beginning of Section 19.2 it can find a set $Q \subset [n]$ with $|Q| = O(k \log n)$ such that

$$\min_{X \in \mathbb{R}^{|Q| \times |T|}} \|A_Q X - A_T\|_1 \leq O(k \log k) \|\Delta_T\|_1 \leq O(\epsilon n^2).$$

Thus, we have

$$\begin{aligned} \min_{X \in \mathbb{R}^{(|Q|+q \cdot t \cdot r) \times n}} \|A_{(Q \cup I)} X - A\|_1 \leq & \min_{X_1 \in \mathbb{R}^{(q \cdot t \cdot r) \times n}} \|A_I X_1 - A_{[n] \setminus T}\|_1 + \min_{X_2 \in \mathbb{R}^{|Q| \times n}} \|A_Q X_2 - A_T\|_1 \\ & \leq (1 + O(\epsilon)) n^2. \end{aligned}$$

Due to Lemma 19.2.1, with probability at least .999, $\|\Delta\|_1 \geq (1 - \epsilon) n^2$, and thus

$$\min_{X \in \mathbb{R}^{(|Q|+q \cdot t \cdot r) \times n}} \|A_{(Q \cup I)} X - A\|_1 \leq (1 + O(\epsilon)) \|\Delta\|_1.$$

□

19.3 Missing Proofs in Section 19.2

19.3.1 Proof of Lemma 19.2.1

Proof. Let $Z \in \mathbb{R}^{n\times n}$ be a random matrix. For each $i, j \in [n]$, define random variable $Z_{i,j}$ as

$$Z_{i,j} = \begin{cases} |\Delta_{i,j}|, & \text{if } |\Delta_{i,j}| \le n; \\ n, & \text{otherwise.} \end{cases}$$

For $i, j \in [n]$, by Markov's inequality, we have

$$\Pr[|\Delta_{i,j}| \ge n] = \Pr[|\Delta_{i,j}|^p \ge n^p] \le \mathbb{E}[|\Delta_{i,j}|^p]/n^p = O(1/n^p). \tag{19.1}$$

Notice that

$$\mathbb{E}[|\Delta_{i,j}|^p] = \int_0^n x^p f(x)\mathrm{d}x + \int_n^\infty x^p f(x)\mathrm{d}x = O(1)$$

where $f(x)$ is the probability density function of $|\Delta_{i,j}|$. Thus we have

$$\int_n^\infty x f(x)\mathrm{d}x \le \int_n^\infty x^p/n^{p-1} \cdot f(x)\mathrm{d}x = O(1/n^{p-1}).$$

Because $\mathbb{E}[|\Delta_{i,j}|] = 1$, we have

$$\int_0^\infty x f(x)\mathrm{d}x = \mathbb{E}[|\Delta_{i,j}|] - \int_n^\infty x f(x)\mathrm{d}x \ge 1 - O(1/n^{p-1}). \tag{19.2}$$

By Equation (19.2), we have

$$\mathbb{E}[Z_{i,j}] = \int_0^n x f(x)dx + n \cdot \Pr[|\Delta_{i,j}| \ge n] \ge \int_0^n x f(x)dx \ge 1 - O(1/n^{p-1}).$$

By Equation (19.1) and $E[|\Delta_{i,j}|^p] \le O(1)$, we have

$$\mathbb{E}[Z_{i,j}^2] = \int_0^n x^2 f(x)\mathrm{d}x + n^2 \Pr[|\Delta_{i,j}| \ge n] \le O(n^{2-p}) + O(n^{2-p}) = O(n^{2-p}).$$

By the inequality of [Mau03],

$$\begin{aligned}\Pr[\mathbb{E}[\|Z\|_1] - \|Z\|_1 \geq \epsilon\,\mathbb{E}[\|Z\|_1]/2] &\leq \exp\left(\frac{-\epsilon^2\,\mathbb{E}[\|Z\|_1]^2/4}{2\sum_{i,j}\mathbb{E}[Z_{i,j}^2]}\right)\\ &\leq \exp\left(\frac{-\epsilon^2(n^2 - O(n^{3-p}))^2/4}{2n^2\cdot O(n^{2-p})}\right)\\ &\leq e^{-\Theta(n)}\end{aligned}$$

Thus with probability at least $1 - e^{-\Theta(n)}$, $\|Z\|_1 \geq (1-\epsilon/2)\,\mathbb{E}[\|Z\|_1] \geq (1-\epsilon)n^2$ where the last inequality follows by $\mathbb{E}[\|Z\|_1 \geq n^2 - O(n^{3-p})]$ and $1/\epsilon = n^{o(1)}$. Since $\|\Delta\|_1 \geq \|Z\|_1$, we complete the proof. □

19.3.2 Proof of Lemma 19.2.2

Proof. Let $Z \in \mathbb{R}^{n\times t}$ be a random matrix where $Z_{i,j}$ are i.i.d. random variables with probability density function:

$$g(x) = \begin{cases} f(x)/\Pr[|\Delta_{1,1}| \leq n^{1/2+1/(2p)}], & \text{if } |x| \leq n^{1/2+1/(2p)};\\ 0, & \text{otherwise.}\end{cases}$$

where $f(x)$ is the probability density function of $\Delta_{1,1}$. (Note that in the above equation, $\Pr[|\Delta_{1,1}| \leq n^{1/2+1/(2p)}] > 0$.) Now, we have $\forall a \geq 0$,

$$\Pr\left[\left\|\sum_{j=1}^{t}\alpha_j\Delta_j\right\|_1 \leq a \;\middle|\; \forall i\in[n], j\in[t], |\Delta_{i,j}| \leq n^{1/2+1/(2p)}\right] = \Pr\left[\left\|\sum_{j=1}^{t}\alpha_j Z_j\right\|_1 \leq a\right].$$

Now we look at the i-th row of $\sum_{j=1}^{t} \alpha_j Z_j$. We have

$$\begin{aligned}
\mathbb{E}\left[\left|\sum_{j=1}^{t} \alpha_j Z_{i,j}\right|\right] &= \left(\mathbb{E}\left[\left|\sum_{j=1}^{t} \alpha_j Z_{i,j}\right|\right]^p\right)^{1/p} \\
&\leq \mathbb{E}\left[\left|\sum_{j=1}^{t} \alpha_j Z_{i,j}\right|^p\right]^{1/p} \\
&\leq \mathbb{E}\left[\left(\left(\sum_{j=1}^{t} \alpha_j^2 Z_{i,j}^2\right)^{1/2}\right)^p\right]^{1/p} \\
&\leq \mathbb{E}\left[\sum_{j=1}^{t} |\alpha_j Z_{i,j}|^p\right]^{1/p} \\
&\leq \left(\sum_{j=1}^{t} \mathbb{E}[|\alpha_j Z_{i,j}|^p]\right)^{1/p} \\
&\leq \left(\sum_{j=1}^{t} \mathbb{E}[|Z_{i,j}|^p]\right)^{1/p} \\
&\leq O(t^{1/p}), \qquad (19.3)
\end{aligned}$$

where the first inequality follows by Jensen's inequality, the second inequality follows by Remark 3 of [Lat97], the third inequality follows by $\|x\|_2 \leq \|x\|_p$ for $p < 2$, the fourth inequality follows by $|\alpha_j| \leq 1$, the fifth inequality follows by $\mathbb{E}[|Z_{i,j}|^p] = \mathbb{E}[|\Delta_{i,j}|^p \mid |\Delta_{1,1}| \leq$

$n^{1/2+1/(2p)}] \leq \mathbb{E}[|\Delta_{i,j}|^p] = O(1)$. For the second moment, we have

$$\begin{aligned}
\mathbb{E}\left[\left|\sum_{j=1}^{t} \alpha_j Z_{i,j}\right|^2\right] &= \sum_{j=1}^{t} \mathbb{E}\left[\alpha_j^2 Z_{i,j}^2\right] + \sum_{j\neq k} \mathbb{E}[\alpha_j \alpha_k Z_{i,j} Z_{i,k}] \\
&= \sum_{j=1}^{t} \alpha_j^2 \,\mathbb{E}\left[Z_{i,j}^2\right] + \sum_{j\neq k} \alpha_j \alpha_k \,\mathbb{E}[Z_{i,j}]\,\mathbb{E}[Z_{i,k}] \\
&\leq \sum_{j=1}^{t} \mathbb{E}\left[Z_{i,j}^2\right] \\
&= t \cdot 2 \int_0^{n^{1/2+1/(2p)}} x^2 f(x) / \Pr\left[|\Delta_{i,j}| \leq n^{1/2+1/(2p)}\right] \mathrm{d}x \\
&\leq 2t / \Pr\left[|\Delta_{i,j}| \leq n^{1/2+1/(2p)}\right] \cdot (n^{1/2+1/(2p)})^{2-p} \int_0^{n^{1/2+1/(2p)}} x^p f(x) \mathrm{d}x \\
&\leq O(tn^{2-p}), \qquad (19.4)
\end{aligned}$$

where the second inequality follows by independence of $Z_{i,j}$ and $Z_{i,k}$. The first inequality follows by $|\alpha_j| \leq 1$ and $\mathbb{E}[Z_{i,j}] = \mathbb{E}[Z_{i,k}] = 0$. The third equality follows by the probability density function of $Z_{i,j}$. The second inequality follows by $x^{2-p} \leq (n^{1/2+1/(2p)})^{2-p}$ when $0 \leq x \leq n^{1/2+1/(2p)}$. The last inequality follows by $\mathbb{E}[|\Delta_{i,j}|^p] = O(1), p > 1$ and $\Pr[|\Delta_{i,j}| \leq n^{1/2+1/(2p)}] \geq 1 - \mathbb{E}[|\Delta_{i,j}|^p]/(n^{1/2+1/(2p)})^p = 1 - O(1/n^{p/2+1/2}) \geq 1/2$.

For $i \in [n]$, define $X_i = |\sum_{j=1}^{t} \alpha_j Z_{i,j}|$. Then, by Bernstein's inequality

$$\begin{aligned}
&\Pr\left[\left\|\sum_{j=1}^{t} \alpha_j Z_j\right\|_1 - \mathbb{E}\left[\left\|\sum_{j=1}^{t} \alpha_j Z_j\right\|_1\right] \geq 0.5t^{1/p}n\right] \\
=\ &\Pr\left[\sum_{i=1}^{n} X_i - \mathbb{E}\left[\sum_{i=1}^{n} X_i\right] \geq 0.5t^{1/p}n\right] \\
\leq\ &\exp\left(-\frac{0.5 \cdot 0.5^2 t^{2/p} n^2}{\sum_{i=1}^{n} \mathbb{E}[X_i^2] + \frac{1}{3} n^{1/2+1/(2p)} \cdot 0.5t^{1/p}n}\right) \\
\leq\ &e^{-n^{\Theta(1)}}.
\end{aligned}$$

The last inequality follows by Equation (19.4). According to Equation (19.3), with probability at least $1 - e^{-n^{\Theta(1)}}$,

$$\left\| \sum_{j=1}^{t} \alpha_j Z_j \right\|_1 \leq \mathbb{E}\left[\left\| \sum_{j=1}^{t} \alpha_j Z_j \right\|_1 \right] + 0.5 t^{1/p} n \leq O(t^{1/p} n).$$

□

19.3.3 Proof of Lemma 19.2.3

Proof. For $i, j \in [n]$, we have

$$\begin{aligned} \Pr\left[|\Delta_{i,j}| > n^{1/2+1/(2p)}\right] &= \Pr\left[|\Delta_{i,j}|^p > n^{p/2+1/2}\right] \\ &\leq \mathbb{E}\left[|\Delta_{i,j}|^p\right] / n^{p/2+1/2} \\ &\leq O(1/n^{p/2+1/2}). \end{aligned}$$

For column j, by taking a union bound,

$$\Pr[j \in H] = \Pr\left[\exists i \in [n], |\Delta_{i,j}| > n^{1/2+1/(2p)}\right] \leq O(1/n^{p/2-1/2}).$$

Thus, $\mathbb{E}[|H|] \leq O(n^{1-(p-1)/2})$. By applying Markov's inequality, we complete the proof. □

19.3.4 Proof of Lemma 19.2.4

Proof. For $l \in \mathbb{N}_{\geq 0}$, define $G_l = \{j \mid \|\Delta_j\|_1 \in (n \cdot 2^l, n \cdot 2^{l+1}]\}$. We have

$$\begin{aligned}
\mathbb{E}[|G_l|] &\leq \sum_{j=1}^{n} \Pr\left[\|\Delta_j\|_1 \geq n \cdot 2^l\right] \\
&= n \Pr\left[\|\Delta_1\|_1 \geq n \cdot 2^l\right] \\
&\leq n \Pr\left[n^{1-1/p}\|\Delta_1\|_p \geq n \cdot 2^l\right] \\
&= n \Pr\left[n^{p-1}\|\Delta_1\|_p^p \geq n^p \cdot 2^{lp}\right] \\
&\leq n \mathbb{E}\left[n^{p-1}\|\Delta_1\|_p^p\right] / (n^p \cdot 2^{lp}) \\
&\leq O(n/2^{lp}).
\end{aligned}$$

The first inequality follows by the definition of G_l. The second inequality follows since $\forall x \in \mathbb{R}^n, \|x\|_1 \leq n^{1-1/p}\|x\|_p$. The third inequality follows by Markov's inequality. The last inequality follows since $\forall i, j \in [n], \mathbb{E}[|\Delta_{i,j}|^p] = O(1)$.

Let $l^* \in \mathbb{N}_{\geq 0}$ satisfy $2^{l^*} < \epsilon r$ and $2^{l^*+1} \geq \epsilon r$. We have

$$\begin{aligned}
\mathbb{E}\left[\sum_{j:\|\Delta_j\|_1 \geq n2^{l^*}} \|\Delta_j\|_1\right] &\leq \mathbb{E}\left[\sum_{l=l^*}^{\infty} |G_l| \cdot n2^{l+1}\right] \\
&= \sum_{l=l^*}^{\infty} \mathbb{E}[|G_l|] \cdot n2^{l+1} \\
&\leq \sum_{l=l^*}^{\infty} O(n/2^{lp}) \cdot n2^{l+1} \\
&= \sum_{l=l^*}^{\infty} O(n^2/2^{l(p-1)}) \\
&= O(n^2/2^{l^*(p-1)}) \\
&= O(n^2/(\epsilon r)^{p-1}) \\
&= O(\epsilon n^2).
\end{aligned}$$

By Markov's inequality, with probability at least .999, $\sum_{j:\|\Delta_j\|_1 \geq n2^{l^*}} \|\Delta_j\|_1 \leq O(\epsilon n^2)$. Conditioned on $\sum_{j:\|\Delta_j\|_1 \geq n2^{l^*}} \|\Delta_j\|_1 \leq O(\epsilon n^2)$, for any $S \subset [n]$ with $|S| \leq n/r$, we have

$$\sum_{j \in S} \|\Delta_j\|_1 \leq |S| \cdot n2^{l^*} + \sum_{j:\|\Delta_j\|_1 \geq n2^{l^*}} \|\Delta_j\|_1 \leq \epsilon n^2 + O(\epsilon n^2) = O(\epsilon n^2).$$

The second inequality follows because $|S| \leq n/r, 2^{l^*} \leq \epsilon r$ and $\sum_{j:\|\Delta_j\|_1 \geq n2^{l^*}} \|\Delta_j\|_1 \leq O(\epsilon n^2)$.

□

19.3.5 Proof of Lemma 19.2.5

Proof. Let $M = n^{1/2+1/(2p)}$. Let $Z \in \mathbb{R}^n$ be a random vector where Z_i are i.i.d. random variables with probability density function

$$g(x) = \begin{cases} f(x)/\Pr[|\Delta_1| \leq M] & \text{if } 0 \leq x \leq M; \\ 0 & \text{otherwise.} \end{cases}$$

where $f(x)$ is the probability density function of $|\Delta_1|$. Then $\forall a > 0$

$$\Pr\left[\|\Delta\|_1 \le a \mid \forall i \in [n], |\Delta_i| \le M\right] = \Pr\left[\|Z\|_1 \le a\right].$$

For $i \in [n]$, because $\mathbb{E}[|\Delta_i|] = 1$, it holds that $\mathbb{E}[Z_i] \le 1$. We have $\mathbb{E}[\sum_{i=1}^{n} Z_i] \le n$. For the second moment, we have

$$\begin{aligned}
\mathbb{E}[Z_i^2] &= \int_0^M x^2 f(x) / \Pr[|\Delta_1| \le M] \mathrm{d}x \\
&\le M^{2-p} / \Pr[|\Delta_1| \le M] \int_0^M x^p f(x) \mathrm{d}x \\
&\le O(M^{2-p}) \\
&\le O(n^{2-p})
\end{aligned}$$

where the second inequality follows by $\mathbb{E}[|\Delta_1|^p] = O(1)$, and

$$\Pr[|\Delta_1| \le M] \ge 1 - \mathbb{E}[|\Delta_1|^p]/M^p \ge 1/2.$$

Then by Bernstein's inequality, we have

$$\begin{aligned}
& \Pr\left[\sum_{i=1}^{n} Z_i - E\left[\sum_{i=1}^{n} Z_i\right] \ge \epsilon n\right] \\
\le\ & \exp\left(\frac{-0.5\epsilon^2 n^2}{\sum_{i=1}^{n} \mathbb{E}[Z_i^2] + \frac{1}{3} M \cdot \epsilon n}\right) \\
\le\ & e^{-n^{\Theta(1)}}.
\end{aligned}$$

Thus,

$$\Pr\left[\|\Delta\|_1 \le (1+\epsilon)n \mid \forall i \in [n], |\Delta_i| \le M\right] = \Pr\left[\|Z\|_1 \le (1+\epsilon)n\right] \ge 1 - e^{-n^{\Theta(1)}}.$$

□

19.3.6 Proof of Lemma 19.2.6

Proof. Recall that $(S_1, S_2, \cdots, S_t, i)$ is equivalent to $(S_{[t]}, i)$. Let $(S_{[t]}, i)$ be an $(A^*, q, t, 1/2)$-good tuple which satisfies $H \cap \left(\bigcup_{j=1}^{t} S_j\right) = \emptyset$. Let C be the core of $(S_{[t]}, i)$. Let $(x_1, x_2, \cdots, x_t)$ be the coefficients tuple corresponding to $(S_{[t]}, i)$. Then we have that

$$
\begin{aligned}
& \left\| \frac{1}{|C|} \sum_{j=1}^{t} A_{S_j} x_j - A_i \right\|_1 \\
= & \left\| \frac{1}{|C|} \sum_{j=1}^{t} \left(A^*_{S_j} + \Delta_{S_j} \right) x_j - (A^*_i + \Delta_i) \right\|_1 \\
\leq & \left\| \frac{1}{|C|} \sum_{j=1}^{t} A^*_{S_j} x_j - A^*_i \right\|_1 + \|\Delta_i\|_1 + \frac{1}{|C|} \left\| \sum_{j=1}^{t} \Delta_{S_j} x_j \right\|_1 \\
= & \|\Delta_i\|_1 + \frac{1}{|C|} \left\| \sum_{j=1}^{t} \Delta_{S_j} x_j \right\|_1 \\
\leq & \|\Delta_i\|_1 + \frac{2}{t} \left\| \sum_{j=1}^{t} \Delta_{S_j} x_j \right\|_1 \\
\leq & \|\Delta_i\|_1 + O\left(\frac{1}{t} \cdot (qt)^{1/p} n \right) \\
= & \|\Delta_i\|_1 + O\left(q^{1/p} / t^{1-1/p} n \right)
\end{aligned}
$$

holds with probability at least $1 - 2^{-n^{\Theta(1)}}$. The first equality follows using $A = A^* + \Delta$. The first inequality follows using the triangle inequality. The second equality follows using the definition of the core and the coefficients tuple (see Definition 19.2.2 and Definition 19.2.4). The second inequality follows using Definition 19.2.2. The third inequality follows by Lemma 19.2.2 and the condition that $H \cap \left(\bigcup_{j=1}^{t} S_j\right) = \emptyset$.

Since the size of $\left|\{i\} \cup \left(\bigcup_{j=1}^{t} S_j\right)\right| = qt + 1$, the total number of $(A^*, q, t, 1/2)-$good tuples is upper bounded by $n^{qt+1} \leq 2^{n^{o(1)}}$. By taking a union bound, we complete the

proof. □

19.3.7 Proof of Lemma 19.2.7

Proof. For $j \in [t]$, by symmetry of the choices of S_j and i, we have $\Pr[i \in R_{A^*}(S_j \cup \{i\})] \leq k/(q+1)$. Thus, by Markov's inequality,

$$\begin{aligned} & \Pr[|\{j \in [t] \mid i \in R_{A^*}(S_j \cup \{i\})\}| > 0.5t] \\ \leq\ & \mathbb{E}[|\{j \in [t] \mid i \in R_{A^*}(S_j \cup \{i\})\}|]/(0.5t) \\ \leq\ & 2k/q. \end{aligned}$$

Thus,

$$\Pr[|\{j \in [t] \mid i \notin R_{A^*}(S_j \cup \{i\})\}| \geq 0.5t] \geq 1 - 2k/q.$$

□

19.3.8 Proof of Lemma 19.2.8

Proof. For $S_1, S_2, \cdots, S_t \in \binom{[n]}{q}$ with $\sum_{j=1}^{t} |S_j| = qt$, define

$$P_{(S_1,S_2,\cdots,S_t)} = \Pr_{i \in [n] \setminus \left(\bigcup_{j=1}^{t} S_j\right)} [(S_1, S_2, \cdots, S_t, i) \text{ is an } (A^*, q, t, 1/2)-\text{good tuple }].$$

Let set T be defined as follows:

$$\left\{ (S_1, S_2, \cdots, S_t) \;\middle|\; S_1, S_2, \cdots, S_t \in \binom{[n]}{q} \text{ with } \sum_{j=1}^{t} |S_j| = qt \right\}.$$

Let G be the set of all the $(A^*, q, t, 1/2)-$good tuples. Then, we have

$$\begin{aligned}
&\Pr_{(S_1,S_2,\cdots,S_t)\sim T}\left[\left|\left\{i \in [n] \setminus \left(\cup_{j=1}^{t} S_j\right) \mid (S_1, S_2, \cdots, S_t, i) \in G\right\}\right| \geq (1-4k/q)(n-qt)\right] \\
&= \frac{1}{|T|}\left|\left\{(S_1, S_2, \cdots, S_t) \mid (S_1, S_2, \cdots, S_t) \in T \text{ and } P_{(S_1,S_2,\cdots,S_t)} \geq 1-4k/q\right\}\right| \\
&= \frac{1}{|T|} \sum_{\substack{(S_1,S_2,\cdots,S_t)\in T \\ P_{(S_1,S_2,\cdots,S_t)}\geq 1-4k/q}} 1 \\
&\geq \frac{1}{|T|} \sum_{\substack{(S_1,S_2,\cdots,S_t)\in T \\ P_{(S_1,S_2,\cdots,S_t)}\geq 1-4k/q}} P_{(S_1,S_2,\cdots,S_t)} \\
&\geq 1 - 2k/q - \frac{1}{|T|} \sum_{\substack{(S_1,S_2,\cdots,S_t)\in T \\ P_{(S_1,S_2,\cdots,S_t)}< 1-4k/q}} P_{(S_1,S_2,\cdots,S_t)} \\
&\geq 1 - 2k/q - (1-4k/q) \\
&\geq 2k/q.
\end{aligned}$$

The second inequality follows from Lemma 19.2.7

$$\frac{1}{|T|} \sum_{\substack{(S_1,S_2,\cdots,S_t)\in T \\ P_{(S_1,S_2,\cdots,S_t)}< 1-4k/q}} P_{(S_1,S_2,\cdots,S_t)} + \frac{1}{|T|} \sum_{\substack{(S_1,S_2,\cdots,S_t)\in T \\ P_{(S_1,S_2,\cdots,S_t)}\geq 1-4k/q}} P_{(S_1,S_2,\cdots,S_t)} \geq 1 - 2k/q.$$

□

19.4 Hardness Result

An overview of the hardness result. Recall that we overcame the column subset selection lower bound of [SWZ17], which shows for entrywise ℓ_1-low rank approximation that there are matrices for which any subset of $\text{poly}(k)$ columns spans at best a $k^{\Omega(1)}$-approximation. Indeed, we came up with a column subset of size $\text{poly}(k(\epsilon^{-1} + \log n))$ spanning a $(1+\epsilon)$-approximation. To do this, we assumed $A = A^* + \Delta$, where A^* is an arbitrary rank-k matrix, and the entries are i.i.d. from a distribution with $\mathbb{E}[|\Delta_{i,j}|] = 1$ and $\mathbb{E}[|\Delta_{i,j}|^p] = O(1)$ for any real number p strictly greater than 1.

Here we show an assumption on the moments is necessary, by showing if instead Δ were drawn from a matrix of i.i.d. Cauchy random variables, for which the p-th moment is undefined or infinite for all $p \geq 1$, then for any subset of $n^{o(1)}$ columns, it spans at best a 1.002 approximation. The input matrix $A = n^C 1 \cdot 1^\top + \Delta$, where $C > 0$ is a constant and we show that $n^{\Omega(1)}$ columns need to be chosen to obtain a 1.001-approximation, even for $k = 1$. Note that this result is stronger than that in [SWZ17] in that it rules out column subset selection even if one were to choose $n^{o(1)}$ columns; the result in [SWZ17] requires at most $\text{poly}(k)$ columns, which for $k = 1$, would just rule out $O(1)$ columns. Our main goal here is to show that a moment assumption on our distribution is necessary, and our result also applies to a symmetric noise distribution which is i.i.d. on all entries, whereas the result of [SWZ17] requires a specific deterministic pattern (namely, the identity matrix) on certain entries.

Our main theorem is given in Theorem 19.4.17. The outline of the proof is as follows. We first condition on the event that $\|\Delta\|_1 \leq \frac{4.0002}{\pi} n^2 \ln n$, which is shown in Lemma 19.4.2 and follows form standard analysis of sums of absolute values of Cauchy random variables.

Thus, it is sufficient to show if we choose any subset S of $r = n^{o(1)}$ columns, denoted by the submatrix A_S, then $\min_{X \in \mathbb{R}^{r \times n}} \|A_S X - A\|_1 \geq \frac{4.01}{\pi} \cdot n^2 \ln n$, as indeed then $\min_{X \in \mathbb{R}^{r \times n}} \|A_S X - A\|_1 \geq 1.002 \|\Delta\|_1$ and we rule out a $(1+\epsilon)$-approximation for ϵ a sufficiently small constant. To this end, we instead show for a fixed S, that $\min_{X \in \mathbb{R}^{r \times n}} \|A_S X - A\|_1 \geq \frac{4.01}{\pi} \cdot n^2 \ln n$ with probability $1 - 2^{-n^{\Theta(1)}}$, and then apply a union bound over all S. To prove this for a single subset S, we argue that for every "coefficient matrix" X, that $\|A_S X - A\|_1 \geq \frac{4.01}{\pi} \cdot n^2 \ln n$.

We show in Lemma 19.4.5, that with probability $1 - (1/n)^{\Theta(n)}$ over Δ, simultaneously for all X, if X has a column X_j with $\|X_j\|_1 \geq n^c$ for a constant $c > 0$, then $\|A_S X_j - A_j\|_1 \geq .9n^3$, which is already too large to provide an $O(1)$-approximation. Note that we need such a high probability bound to later union bound over *all* S. Lemma 19.4.5 is in turn shown via a net argument on all X_j (it suffices to prove this for a single $j \in [n]$, since there are only n different j, so we can union bound over all j). The net bounds are given in Definition 19.4.1 and Definition 19.4.4, and the high probability bound for a given coefficient vector X_j is shown in Lemma 19.4.3, where we use properties of the Cauchy distribution. Thus, we can assume $\|X_j\|_1 < n^c$ for all $j \in [n]$. We also show in Fact 19.4.1, conditioned on the fact that $\|\Delta\|_1 \leq \frac{4.002}{\pi} n^2 \ln n$, it holds that for *any* vector X_j, if $\|X_j\|_1 < n^c$ and $|1 - \mathbf{1}^\top X_j| > 1 - 10^{-20}$, then $\|A_S X - A\|_1 \geq \|A_S X_j - A_j\|_1 > n^3$. The intuition here is $A = n^{c_0} \mathbf{1} \cdot \mathbf{1}^\top + \Delta$ for a large constant c_0, and X_j does not have enough norm ($\|X_j\|_1 \leq n^c$) or correlation with the vector $\mathbf{1}$ ($|1 - \mathbf{1}^\top X_j| > 1 - 10^{-20}$) to make $\|A_S X_j - A_j\|_1$ small.

Given the above, we can assume both that $\|X_j\|_1 \leq n^c$ and $|1 - \mathbf{1}^\top X_j| \leq 1 - 10^{-20}$ for all columns j of our coefficient matrix X. We can also assume that $\|A_S X - A\|_1 \leq 4n^2 \ln n$, as otherwise such an X already satisfies $\|A_S X - A\|_1 \geq \frac{4.01}{\pi} \cdot n^2 \ln n$ and we are done. To analyze $\|A_S X - A\|_1 = \sum_{i,j} |(A_S X - A_{[n] \setminus S})_{i,j}|$ in Theorem 19.4.17, we then split the sum over

"large coordinates" (i,j) for which $|\Delta_{i,j}| > n^{1.0002}$, and "small coordinates" (i,j) for which $|\Delta_{i,j}| < n^{.9999}$, and since we seek to lower bound $\|A_S X - A_{[n]\setminus S}\|_1$, we drop the remaining coordinates (i,j). To handle large coordinates, we observe that since the column span of A_S is only $r = n^{o(1)}$-dimensional, as one ranges over all vectors y in its span of 1-norm, say, $O(n^2 \ln n)$, there is only a small subset T, of size at most $n^{.99999}$ of coordinates $i \in [n]$ for which we could ever have $|y_i| \geq n^{1.0001}$. We show this in Lemma 19.4.7. This uses the property of vectors in low-dimensional subspaces, and has been exploited in earlier works in the context of designing so-called subspace embeddings [CW13, MM13]. We call T the "bad region" for A_S. While the column span of A_S depends on Δ_S, it is independent of $\Delta_{[n]\setminus S}$, and thus it is extremely unlikely that the large coordinate of Δ_S "match up" with the bad region of A_S. This is captured in Lemma 19.4.10, where we show that if $\|A_S X - A_{[n]\setminus S}\|_1 \leq 4n^2 \ln n$ (as we said we could assume above), then $\sum_{\text{large coordinates } i,j} |(A_S X - A_{[n]\setminus S})_{i,j}|$ is at least $\frac{1.996}{\pi} n^2 \ln n$. Intuitively, the heavy coordinates make up about $\frac{2}{\pi} n^2 \ln n$ of the total mass of $\|\Delta\|_1$, by tail bounds of the Cauchy distribution, and for any set S of size $n^{o(1)}$, A_S fits at most a small portion of this, still leaving us left with $\frac{1.996}{\pi} n^2 \ln n$ in cost. Our goal is to show that $\|A_S X - A_{[n]\setminus S}\|_1 \geq \frac{4.01}{\pi} \cdot n^2 \ln n$, so we still have a way to go.

We next analyze $\sum_{\text{small coordinates } i,j} |(A_S X - A_{[n]\setminus S})_{i,j}|$. Via Bernstein's inequality, in Lemma 19.4.11 we argue that for any fixed vector y and random vector Δ_j of i.i.d. Cauchy entries, roughly half of the contribution of coordinates to $\|\Delta_j\|_1$ will come from coordinates j for which $\text{sign}(y_j) = \text{sign}(\Delta_j)$ and $|\Delta_j| \leq n^{.9999}$, giving us a contribution of roughly $\frac{.9998}{\pi} n \ln n$ to the cost. The situation we will actually be in, when analyzing a column of $A_S X - A_{[n]\setminus S}$, is that of taking the sum of two independent Cauchy vectors, shifted by a multiple of $\mathbf{1}^\top$. We analyze this setting in Lemma 19.4.13, after first conditioning on certain level sets having

typical behavior in Lemma 19.4.12. This roughly doubles the contribution, gives us roughly a contribution of $\frac{1.996}{\pi} n^2 \ln n$ from coordinates j for which (i, j) is a small coordinate and we look at coordinates i on which the sum of two independent Cauchy vectors have the same sign. Combined with the contribution from the heavy coordinates, this gives us a cost of roughly $\frac{3.992}{\pi} n^2 \ln n$, which still falls short of the $\frac{4.01}{\pi} \cdot n^2 \ln n$ total cost we are aiming for. Finally, if we sum up two independent Cauchy vectors and look at the contribution to the sum from coordinates which disagree in sign, due to the anti-concentration of the Cauchy distribution we can still "gain a little bit of cost" since the values, although differing in sign, are still likely not to be very close in magnitude. We formalize this in Lemma 19.4.14. We combine all of the costs from small coordinates in Lemma 19.4.15, where we show we obtain a contribution of at least $\frac{2.025}{\pi} n \ln n$. This is enough, when combined with our earlier $\frac{1.996}{\pi} n^2 \ln n$ contribution from the heavy coordinates, to obtain an overall $\frac{4.01}{\pi} \cdot n^2 \ln n$ lower bound on the cost, and conclude the proof of our main theorem in Theorem 19.4.17.

In the remaining sections, we will present detailed proofs.

19.4.1 A Useful Fact

Fact 19.4.1. *Let $c_0 > 0$ be a sufficiently large constant. Let $u = n^{c_0} \cdot \mathbf{1} \in \mathbb{R}^n$ and $\Delta \in \mathbb{R}^{n \times (d+1)}$. If $\sum_{i=1}^{d+1} \|\Delta_i\|_1 \leq n^3$ and if $\alpha \in \mathbb{R}^d$ satisfies $|1 - \mathbf{1}^\top \alpha| > 1/n^{c_1}$ and $\|\alpha\|_1 \leq n^c$, where $0 < c < c_0 - 10$ is a constant and $c_1 > 3$ is another constant depending on c_0, c, then*

$$\|u - u\mathbf{1}^\top \alpha + \Delta_{d+1} - \Delta_{[d]}\alpha\|_1 > n^3.$$

Proof.

$$\begin{aligned}
&\|u - u\mathbf{1}^\top\alpha + \Delta_{d+1} - \Delta_{[d]}\alpha\|_1 \\
&\geq |1 - \mathbf{1}^\top\alpha| \cdot \|u\|_1 - \|\Delta_{d+1}\|_1 - \|\Delta_{[d]}\alpha\|_1 \\
&\geq |1 - \mathbf{1}^\top\alpha| \cdot n \cdot n^{c_0} - n^3 - n^4\|\alpha\|_1 \\
&\geq |1 - \mathbf{1}^\top\alpha| \cdot n \cdot n^{c_0} - n^{5+c} \\
&\geq n^{c_0+1-c_1} - n^{5+c} \\
&\geq n^3.
\end{aligned}$$

The first inequality follows by the triangle inequality. The second inequality follows since $u = n^{c_0} \cdot \mathbf{1} \in \mathbb{R}^n$ and $\sum_{i=1}^{d+1} \|\Delta_i\|_1 \leq n^3$. The third inequality follows since $\|\alpha\|_1 \leq n^c$. The fourth inequality follows since $|1 - \mathbf{1}^\top\alpha| > 1/n^{c_1}$. The last inequality follows since $c_0 - c_1 > c + 5$. □

19.4.2 One-Sided Error Concentration Bound for a Random Cauchy Matrix

Lemma 19.4.2 (Lower bound on the cost)**.** *If n is sufficiently large, then*

$$\Pr_{\Delta \sim \{C(0,1)\}^{n \times n}} \left[\|\Delta\|_1 \leq \frac{4.0002}{\pi} n^2 \ln n \right] \geq 1 - O(1/\log\log n).$$

Proof. Let $\Delta \in \mathbb{R}^{n \times n}$ be a random matrix such that each entry is an i.i.d. $C(0,1)$ random Cauchy variable. Let $B = n^2 \ln\ln n$. Let $Z \in \mathbb{R}^{n \times n}$ and $\forall i, j \in [n]$,

$$Z_{i,j} = \begin{cases} |\Delta_{i,j}| & |\Delta_{i,j}| < B \\ B & \text{Otherwise} \end{cases}.$$

For fixed $i, j \in [n]$, we have

$$\begin{aligned}
\mathbb{E}[Z_{i,j}] &= \frac{2}{\pi}\int_0^B \frac{x}{1+x^2}\mathrm{d}x + \Pr[|\Delta_{i,j}| \geq B] \cdot B \\
&= \frac{1}{\pi}\ln(B^2+1) + \Pr[|\Delta_{i,j}| \geq B] \cdot B \\
&\leq \frac{1}{\pi}\ln(B^2+1) + 1
\end{aligned}$$

where the first inequality follows by the cumulative distribution function of a half Cauchy random variable. We also have $\mathbb{E}[Z_{i,j}] \geq \frac{1}{\pi}\ln(B^2+1)$. For the second moment, we have

$$\begin{aligned}
\mathbb{E}[Z_{i,j}^2] &= \frac{2}{\pi}\int_0^B \frac{x^2}{1+x^2}\mathrm{d}x + \Pr[|\Delta_{i,j}| \geq B] \cdot B^2 \\
&= \frac{2}{\pi}(B - \tan^{-1} B) + \Pr[|\Delta_{i,j}| \geq B] \cdot B^2 \\
&\leq \frac{2}{\pi}B + B \\
&\leq 2B
\end{aligned}$$

where the first inequality follows by the cumulative distribution function of a half Cauchy random variable. By applying Bernstein's inequality, we have

$$\begin{aligned}
&\Pr\left[\|Z\|_1 - \mathbb{E}[\|Z\|_1] > 0.0001\,\mathbb{E}[\|Z\|_1]\right] \\
\leq\ &\exp\left(-\frac{0.5 \cdot 0.0001^2\,\mathbb{E}[\|Z\|_1]^2}{n^2 \cdot 2B + \frac{1}{3}B \cdot 0.0001\,\mathbb{E}[\|Z\|_1]}\right) \\
\leq\ &\exp(-\Omega(\ln n / \ln\ln n)) \\
\leq\ &O(1/\ln n). \qquad (19.5)
\end{aligned}$$

The first inequality follows by the definition of Z and the second moment of $Z_{i,j}$. The second

inequality follows from $\mathbb{E}[\|Z\|_1] = \Theta(n^2 \ln n)$ and $B = \Theta(n^2 \ln \ln n)$. Notice that

$$\begin{aligned}
& \Pr\left[\|\Delta\|_1 > \frac{4.0002}{\pi} n^2 \ln n\right] \\
= \ & \Pr\left[\|\Delta\|_1 > \frac{4.0002}{\pi} n^2 \ln n \mid \forall i,j, |\Delta_{i,j}| < B\right] \Pr\left[\forall i,j, |\Delta_{i,j}| < B\right] \\
& + \Pr\left[\|\Delta\|_1 > \frac{4.0002}{\pi} n^2 \ln n \mid \exists i,j, |\Delta_{i,j}| \geq B\right] \Pr\left[\exists i,j, |\Delta_{i,j}| \geq B\right] \\
\leq \ & \Pr\left[\|\Delta\|_1 > \frac{4.0002}{\pi} n^2 \ln n \mid \forall i,j, |\Delta_{i,j}| < B\right] + \Pr\left[\exists i,j, |\Delta_{i,j}| \geq B\right] \\
\leq \ & \Pr\left[\|Z\|_1 > \frac{4.0002}{\pi} n^2 \ln n\right] + \Pr\left[\exists i,j, |\Delta_{i,j}| \geq B\right] \\
\leq \ & \Pr\left[\|Z\|_1 > \frac{4.0002}{\pi} n^2 \ln n\right] + n^2 \cdot 1/B \\
\leq \ & \Pr\left[\|Z\|_1 > 1.0001\, \mathbb{E}[\|Z\|_1]\right] + n^2 \cdot 1/B \\
\leq \ & O(1/\log(n)) + O(1/\log\log n) \\
\leq \ & O(1/\log\log n)
\end{aligned}$$

The second inequality follows by the definition of Z. The third inequality follows by the union bound and the cumulative distribution function of a half Cauchy random variable. The fourth inequality follows from $\mathbb{E}[\|Z\|_1] \leq n^2(1/\pi \cdot \ln(B^2+1)+1) \leq 4.0000001/\pi \cdot n^2 \ln n$ when n is sufficiently large. □

19.4.3 "For Each" Guarantee

In the following Lemma, we show that, for each fixed coefficient vector α, if the entry of α is too large, the fitting cost cannot be small.

Lemma 19.4.3 (For each fixed α, the entry cannot be too large)**.** *Let $c > 0$ be a sufficiently*

large constant, $n \geq d \geq 1$, $u \in \mathbb{R}^n$ *be any fixed vector and* $\Delta \in \mathbb{R}^{n \times d}$ *be a random matrix where* $\forall i \in [n], j \in [d], \Delta_{i,j} \sim C(0,1)$ *independently. For any fixed* $\alpha \in \mathbb{R}^d$ *with* $\|\alpha\|_1 = n^c$,

$$\Pr_{\Delta \sim \{C(0,1)\}^{n \times d}}[\|(u \cdot \mathbf{1}^\top + \Delta)\alpha\|_1 > n^3] > 1 - (1/n)^{\Theta(n)}.$$

Proof. Let c be a sufficiently large constant. Let $\alpha \in \mathbb{R}^d$ with $\|\alpha\|_1 = n^c$. Let $u \in \mathbb{R}^n$ be any fixed vector. Let $\Delta \in \mathbb{R}^{n \times d}$ be a random matrix where $\forall i \in [n], j \in [d], \Delta_{i,j} \sim C(0,1)$. Then $\Delta\alpha \in \mathbb{R}^n$ is a random vector with each entry drawn independently from $C(0, \|\alpha\|_1)$. Due to the probability density function of standard Cauchy random variables,

$$\Pr[\|\Delta\alpha\|_1 < n^3] \geq \Pr[\|\Delta\alpha + u \cdot \mathbf{1}^\top \alpha\|_1 < n^3].$$

It suffices to upper bound $\Pr[\|\Delta\alpha\|_1 < n^3]$. If $c > 10$, then due to the cumulative distribution function of Cauchy random variables, for a fixed $i \in [n]$, $\Pr[|(\Delta\alpha)_i| < n^3] < 1/n$. Thus, $\Pr[\|\Delta\alpha\|_1 < n^3] < (\frac{1}{n})^n$. Thus,

$$\Pr_{\Delta \sim \{C(0,1)\}^{n \times d}}[\|(u \cdot \mathbf{1}^\top + \Delta)\alpha\|_1 > n^3] > 1 - (1/n)^n.$$

□

19.4.4 From "For Each" to "For All" via an ϵ-Net

Definition 19.4.1 (ϵ-net for the ℓ_1-norm ball)**.** Let $A \in \mathbb{R}^{n \times d}$ have rank d, and let $L = \{y \in \mathbb{R}^n \mid y = Ax, x \in \mathbb{R}^d\}$ be the column space of A. An ϵ-net of the ℓ_1-unit sphere $\mathcal{S}^{d-1} = \{y \mid \|y\|_1 = 1, y \in L\} \subset L$ is a set $N \subset \mathcal{S}^{d-1}$ of points for which $\forall y \in \mathcal{S}^{d-1}, \exists y' \in N$ for which $\|y - y'\| \leq \epsilon$.

[DDH+09] proved an upper bound on the size of an ϵ-net.

Lemma 19.4.4 (See, e.g., the ball B on page 2068 of [DDH+09])**.** *Let $A \in \mathbb{R}^{n \times d}$ have rank d, and let $L = \{y \in \mathbb{R}^n \mid y = Ax, x \in \mathbb{R}^d\}$ be the column space of A. For $\epsilon \in (0,1)$, an ϵ-net (Definition 19.4.1) N of the ℓ_1-unit sphere $\mathcal{S}^{d-1} = \{y \mid \|y\|_1 = 1, y \in L\} \subset L$ exists. Furthermore, the size of N is at most $(3/\epsilon)^d$.*

Lemma 19.4.5 (For all possible α, the entry cannot be too large)**.** *Let $n \geq 1, d = n^{o(1)}$. Let $u = n^{c_0} \cdot \mathbf{1} \in \mathbb{R}^n$ denote a fixed vector where c_0 is a constant. Let $\Delta \in \mathbb{R}^{n \times d}$ be a random matrix where $\forall i \in [n], j \in [d], \Delta_{i,j} \sim C(0,1)$ independently. Let $c > 0$ be a sufficiently large constant. Conditioned on $\|\Delta\|_1 \leq n^3$, with probability at least $1 - (1/n)^{\Theta(n)}$, for all $\alpha \in \mathbb{R}^d$ with $\|\alpha\|_1 \geq n^c$, we have $\|(u \cdot \mathbf{1}^\top + \Delta)\alpha\|_1 > 0.9n^3$.*

Proof. Due to Lemma 19.4.4, there is a set $N \subset \{\alpha \in \mathbb{R}^d \mid \|\alpha\|_1 = n^c\} \subset \mathbb{R}^d$ with $|N| \leq 2^{\Theta(d \log n)}$ such that $\forall \alpha \in \mathbb{R}^d$ with $\|\alpha\|_1 = n^c$, $\exists \alpha' \in N$ such that $\|\alpha - \alpha'\|_1 \leq 1/n^{c'}$ where $c' > c_0 + 100$ is a constant. By applying Lemma 19.4.3 and union bounding over all the points in N, with probability at least $1 - (1/n)^n \cdot |N| \geq 1 - (1/n)^n \cdot 2^{n^{o(1)}} = 1 - (1/n)^{\Theta(n)}$, $\forall \alpha' \in N$, $\|(u \cdot \mathbf{1}^\top + \Delta)\alpha'\|_1 > n^3$. $\forall \alpha \in \mathbb{R}^d$ with $\|\alpha\|_1 = n^c$, we can find $\alpha' \in N$ such that

$\|\alpha - \alpha'\|_1 \leq 1/n^{c'}$. Let $\gamma = \alpha - \alpha'$. Then,

$$\begin{aligned}
&\|(u \cdot \mathbf{1}^\top + \Delta)\alpha\|_1 \\
= &\|(u \cdot \mathbf{1}^\top + \Delta)(\alpha' + \gamma)\|_1 \\
\geq &\|(u \cdot \mathbf{1}^\top + \Delta)\alpha'\|_1 - \|(u \cdot \mathbf{1}^\top + \Delta)\gamma\|_1 \\
\geq &\, n^3 - \sqrt{n}\|(u \cdot \mathbf{1}^\top + \Delta)\gamma\|_2 \\
\geq &\, n^3 - \sqrt{n}(\|u \cdot \mathbf{1}^\top\|_2 + \|\Delta\|_2)\|\gamma\|_2 \\
\geq &\, n^3 - n^{c_0+50}/n^{c'} \\
\geq &\, 0.9n^3.
\end{aligned}$$

The first equality follows from $\alpha = \alpha' + \gamma$. The first inequality follows by the triangle inequality. The second inequality follows by the relaxation from the ℓ_1 norm to the ℓ_2 norm. The third inequality follows from the operator norm and the triangle inequality. The fourth inequality follows using $\|\Delta\|_2 \leq \|\Delta\|_1 \leq n^3, \|u\|_2 \leq n^{c_0+10}, \|\gamma\|_2 \leq \|\gamma\|_1 \leq (1/n)^{c'}$. The last inequality follows since $c' > c_0 + 100$.

For $\alpha \in \mathbb{R}^n$ with $\|\alpha\|_1 > n^c$, let $\alpha' = \alpha/\|\alpha\|_1 \cdot n^c$. Then

$$\|(u \cdot \mathbf{1}^\top + \Delta)\alpha\|_1 \geq \|(u \cdot \mathbf{1}^\top + \Delta)\alpha'\|_1 \geq 0.9n^3.$$

□

19.4.5 Bounding the Cost from the Large-Entry Part via "Bad" Regions

In this section, we will use the concept of *well-conditioned basis* in our analysis.

Definition 19.4.2 (Well-conditioned basis [DDH+09])**.** Let $A \in \mathbb{R}^{n \times m}$ have rank d. Let $p \in [1, \infty)$, and let $\|\cdot\|_q$ be the dual norm of $\|\cdot\|_p$, i.e., $1/p + 1/q = 1$. If $U \in \mathbb{R}^{n \times d}$ satisfies

1. $\|U\|_p \leq \alpha$,

2. $\forall z \in \mathbb{R}^d, \|z\|_q \leq \beta \|Uz\|_p$,

then U is an (α, β, p) well-conditioned basis for the column space of A.

The following theorem gives an existence result of a well-conditioned basis.

Theorem 19.4.6 (ℓ_1 well-conditioned basis [DDH+09])**.** *Let $A \in \mathbb{R}^{n \times m}$ have rank d. There exists $U \in \mathbb{R}^{n \times d}$ such that U is a $(d, 1, 1)$ well-conditioned basis for the column space of A.*

In the following lemma, we consider vectors from low-dimensional subspaces. For a coordinate, if there is a vector from the subspace for which this entry is large, but the norm of the vector is small, then this kind of coordinate is pretty "rare". More formally,

Lemma 19.4.7. *Given a matrix $U \in \mathbb{R}^{n \times r}$ for a sufficiently large $n \geq 1$, let $r = n^{o(1)}$. Let $S = \{y | y = Ux, x \in \mathbb{R}^r\}$. Let the set T denote $\{i \in [n] \mid \exists y \in S, |y_i| \geq n^{1.0001}$ and $\|y\|_1 < 8n^2 \ln n\}$. Then we have*

$$|T| \leq n^{0.99999}.$$

Proof. Due to Theorem 19.4.6, let $U \in \mathbb{R}^{n \times r}$ be the $(r, 1, 1)$ well-conditioned basis of the column space of U. If $i \in T$, then $\exists x \in \mathbb{R}^r$ such that $|(Ux)_i| \geq n^{1.0001}$ and $\|Ux\|_1 < 8n^2 \ln n$. Thus, we have

$$n^{1.0001} \leq |(Ux)_i| \leq \|U^i\|_1 \|x\|_\infty \leq \|U^i\|_1 \|Ux\|_1 \leq \|U^i\|_1 \cdot 8n^2 \ln n.$$

The first inequality follows using $n^{1.0001} \leq |(Ux)_i|$. The second inequality follows by Hölder's inequality. The third inequality follows by the second property of the well-conditioned basis. The fourth inequality follows using $\|Ux\|_1 < 8n^2 \ln n$. Thus, we have

$$\|U^i\|_1 \geq n^{1.0001}/n^{2+o(1)} \geq 1/n^{0.9999-o(1)}.$$

Notice that $\sum_{j=1}^{n} \|U^j\|_1 = \|U\|_1 \leq r$. Thus,

$$|T| \leq r/(1/n^{0.9999-o(1)}) = n^{0.9999+o(1)} \leq n^{0.99999}.$$

□

Definition 19.4.3 (Bad region)**.** Given a matrix $U \in \mathbb{R}^{n \times r}$, we say $\mathcal{B}(U) = \{i \in [n] \mid \exists y \in \text{colspan}(U) \subset \mathbb{R}^n \text{ s.t. } y_i \geq n^{1.0001} \text{ and } \|y\|_1 \leq 8n^2 \ln n\}$ is a bad region for U.

Next we state a lower and an upper bound on the probability that a Cauchy random variable is in a certain range,

Claim 19.4.8. *Let $X \sim C(0,1)$ be a standard Cauchy random variable. Then for any $x > 1549$,*

$$\frac{2}{\pi} \cdot \frac{\ln(1.001)}{x} \geq \Pr[|X| \in (x, 1.001x]] \geq \frac{1.999}{\pi} \cdot \frac{\ln(1.001)}{x}.$$

Proof. When $x > 1549$, $\frac{2}{\pi} \cdot \frac{\ln(1.001)}{x} \geq \frac{2}{\pi} \cdot (\tan^{-1}(1.001x) - \tan^{-1}(x)) \geq \frac{1.999}{\pi} \cdot \frac{\ln(1.001)}{x}$. □

We build a level set for the "large" noise values, and we show the bad region cannot cover much of the large noise. The reason is that the bad region is small, and for each row, there is always some large noise.

Lemma 19.4.9. *Given a matrix $U \in \mathbb{R}^{n\times r}$ with n sufficiently large, let $r = n^{o(1)}$, and consider a random matrix $\Delta \in \mathbb{R}^{n\times(n-r)}$ with $\Delta_{i,j} \sim C(0,1)$ independently. Let $L_t = \{(i,j) \mid (i,j) \in [n]\times[n-r], |\Delta_{i,j}| \in (1.001^t, 1.001^{t+1}]\}$. With probability at least $1-1/2^{n^{\Theta(1)}}$, for all $t \in (\frac{1.0002\ln n}{\ln 1.001}, \frac{1.9999\ln n}{\ln 1.001}) \cap \mathbb{N}$,*

$$|L_t \setminus (\mathcal{B}(U)\times[n-r])| \geq n(n-r)\cdot 1.998\cdot\ln(1.001)/(\pi\cdot 1.001^t).$$

Proof. Let $N = n\cdot(n-r)$. Then according to Claim 19.4.8, $\forall t \in (\frac{1.0002\ln n}{\ln 1.001}, \frac{1.9999\ln n}{\ln 1.001}) \cap \mathbb{N}$, $\mathbb{E}(|L_t|) \geq N\cdot 1.999\cdot\ln(1.001)/(\pi\cdot 1.001^t) \geq n^{\Theta(1)}$. For a fixed t, by a Chernoff bound, with probability at least $1-1/2^{n^{\Theta(1)}}$, $|L_t| \geq N\cdot 1.9989\cdot\ln(1.001)/(\pi\cdot 1.001^t)$. Due to Lemma 19.4.7, $|\mathcal{B}(U)\times[n-r]| \leq n^{0.99999}(n-r) = N/n^{0.00001}$. Due to the Chernoff bound, with probability at least $1-1/2^{n^{\Theta(1)}}$, $|L_t \cap (\mathcal{B}(U)\times[n-r])| < N/n^{0.00001}\cdot 2.0001\cdot\ln(1.001)/(\pi\cdot 1.001^t)$. Thus, with probability at least $1-1/2^{n^{\Theta(1)}}$, $|L_t\setminus(\mathcal{B}(U)\times[n-r])| \geq N\cdot 1.998\cdot\ln(1.001)/(\pi\cdot 1.001^t)$. By taking a union bound over all $t \in (\frac{1.0002\ln n}{\ln 1.001}, \frac{1.9999\ln n}{\ln 1.001}) \cap \mathbb{N}$, we complete the proof. □

Lemma 19.4.10 (The cost of the large noise part)**.** *Let $n \geq 1$ be sufficiently large, and let $r = n^{o(1)}$. Given a matrix $U \in \mathbb{R}^{n\times r}$, and a random matrix $\Delta \in \mathbb{R}^{n\times(n-r)}$ with $\Delta_{i,j} \sim C(0,1)$ independently, let $\mathfrak{I} = \{(i,j) \in [n]\times[n-r] \mid |\Delta_{i,j}| \geq n^{1.0002}\}$. If $\|\Delta\|_1 \leq 4n^2\ln n$, then with probability at least $1-1/2^{n^{\Theta(1)}}$, for all $X \in \mathbb{R}^{r\times n}$, either*

$$\sum_{(i,j)\in\mathfrak{I}} |(UX-\Delta)_{i,j}| > \frac{1.996}{\pi}n^2\ln n,$$

or

$$\|UX-\Delta\|_1 > 4n^2\ln n$$

Proof.

$$\begin{aligned}
&\sum_{(i,j)\in\mathcal{I}} |(UX-\Delta)_{i,j}| \\
\geq &\sum_{(i,j)\in\mathcal{I}\setminus\mathcal{B}(U)} |(UX-\Delta)_{i,j}| \\
\geq &\sum_{(i,j)\in\mathcal{I}\setminus\mathcal{B}(U)} |(\Delta)_{i,j}| - \sum_{(i,j)\in\mathcal{I}\setminus\mathcal{B}(U)} |(UX)_{i,j}| \qquad (19.6)
\end{aligned}$$

Let $N = n(n-r)$. By a Chernoff bound and the cumulative distribution function of a Cauchy random variable, with probability at least $1 - 1/2^{n^{\Theta(1)}}$, $|\mathcal{I}| \leq 1.1 \cdot N/n^{1.0002}$. If $\exists(i,j) \in \mathcal{I} \setminus \mathcal{B}(U)$ which has $|(UX)_{i,j}| > n^{1.0001}$, then according to the definition of $\mathcal{B}(U)$, $\|UX\|_1 \geq \|(UX)_j\|_1 \geq 8n^2 \ln n$. Due to the triangle inequality, $\|UX - \Delta\|_1 \geq \|UX\|_1 - \|\Delta\|_1 \geq 4n^2 \ln n$. If $\forall(i,j) \in \mathcal{I} \setminus \mathcal{B}(U)$ we have $|(UX)_{i,j}| \leq n^{1.0001}$, then

$$\sum_{(i,j)\in\mathcal{I}\setminus\mathcal{B}(U)} |(UX)_{i,j}| \leq |\mathcal{I}| \cdot n^{1.0001} \leq 1.1 \cdot N/n^{0.0001}. \qquad (19.7)$$

Due to Lemma 19.4.9, with probability at least $1 - 1/2^{n^{\Theta(1)}}$,

$$\begin{aligned}
&\sum_{(i,j)\in\mathcal{I}\setminus\mathcal{B}(U)} |(\Delta)_{i,j}| \\
\geq &\sum_{t\in(\frac{1.0002\ln n}{\ln 1.001}, \frac{1.9999\ln n}{\ln 1.001})\cap\mathbb{N}} 1.001^t \cdot N \cdot 1.998 \cdot \ln(1.001)/(\pi \cdot 1.001^t) \\
\geq &\frac{1.997}{\pi} \cdot N \ln n. \qquad (19.8)
\end{aligned}$$

We plug (19.7) and (19.8) into (19.6), from which we have

$$\sum_{(i,j)\in\mathcal{I}} |(UX-\Delta)_{i,j}| \geq \frac{1.996}{\pi} n^2 \ln n.$$

□

19.4.6 Cost from the Sign-Agreement Part of the Small-Entry Part

We use $-y$ to fit Δ (we think of $A_S\alpha = A_S^*\alpha - y$, and want to minimize $\|-y-\Delta\|_1$). If the sign of y_j is the same as the sign of Δ_j, then both coordinate values will collectively contribute.

Lemma 19.4.11 (The contribution from Δ_i when Δ_i and y_i have the same sign)**.** *Suppose we are given a vector $y \in \mathbb{R}^n$ and a random vector $\Delta \in \mathbb{R}^n$ with $\Delta_j \sim C(0,1)$ independently. Then with probability at least $1 - 1/2^{n^{\Theta(1)}}$,*

$$\sum_{j \,:\, \mathrm{sign}(y_j)=\mathrm{sign}(\Delta_j) \text{ and } |\Delta_j| \leq n^{0.9999}} |\Delta_j| > \frac{0.9998}{\pi} n \ln n.$$

Proof. For $j \in [n]$, define the random variable

$$Z_j = \begin{cases} \Delta_j & 0 < \Delta_j \leq n^{0.9999} \\ 0 & \text{otherwise} \end{cases}.$$

Then, we have

$$\Pr\left[\sum_{j \,:\, \mathrm{sign}(y_j)=\mathrm{sign}(\Delta_{i,j}) \text{ and } |\Delta_j| \leq n^{0.9999}} |\Delta_j| > \frac{0.9998}{\pi} n \ln n\right] = \Pr\left[\sum_{j=1}^{n} Z_j > \frac{0.9998}{\pi} n \ln n\right].$$

Let $B = n^{0.9999}$. For $j \in [n]$,

$$\mathbb{E}[Z_j] = \frac{1}{\pi}\int_0^B \frac{x}{1+x^2}\mathrm{d}x = \frac{1}{2\pi}\ln(B^2+1).$$

Also,

$$\mathbb{E}[Z_j^2] = \frac{1}{\pi}\int_0^B \frac{x^2}{1+x^2}\mathrm{d}x = \frac{B - \tan^{-1}(B)}{\pi} \leq B.$$

By Bernstein's inequality,

$$\begin{aligned}
&\Pr\left[\mathbb{E}\left[\sum_{j=1}^{n} Z_j\right] - \sum_{j=1}^{n} Z_j > 10^{-5}\,\mathbb{E}\left[\sum_{j=1}^{n} Z_j\right]\right] \\
\leq\ &\exp\left(-\frac{0.5\cdot\left(10^{-5}\,\mathbb{E}\left[\sum_{j=1}^{n} Z_j\right]\right)^2}{\sum_{j=1}^{n}\mathbb{E}[Z_j^2] + \frac{1}{3}B\cdot 10^{-5}\,\mathbb{E}\left[\sum_{j=1}^{n} Z_j\right]}\right) \\
\leq\ &\exp\left(-\frac{5\cdot 10^{-11} n^2 \ln^2(B^2+1)/(4\pi^2)}{nB + \frac{1}{3}B\cdot 10^{-5} n\ln(B^2+1)/(2\pi)}\right) \\
\leq\ &e^{-n^{\Theta(1)}}.
\end{aligned}$$

The last inequality follows since $B = n^{0.9999}$. Thus, we have

$$\Pr\left[\sum_{j=1}^{n} Z_j < 0.9998/\pi\cdot n\ln n\right] \leq \Pr\left[\sum_{j=1}^{n} Z_j < 0.99999 n\ln(B^2+1)/(2\pi)\right] \leq e^{-n^{\Theta(1)}}.$$

□

Lemma 19.4.12 (Bound on level sets of a Cauchy vector)**.** *Suppose we are given a random vector $y\in\mathbb{R}^n$ with $y_i\sim C(0,1)$ chosen independently. Let*

$$L_t^- = \{i\in[n] \mid -y_i\in(1.001^t, 1.001^{t+1}]\} \text{ and } L_t^+ = \{i\in[n]\mid y_i\in(1.001^t,1.001^{t+1}]\}.$$

With probability at least $1-1/2^{n^{\Theta(1)}}$, for all $t\in(\frac{\ln 1549}{\ln 1.001}, \frac{0.9999\ln n}{\ln 1.001})\cap\mathbb{N}$,

$$\min(|L_t^-|, |L_t^+|) \geq 0.999n\cdot\frac{1}{\pi}\frac{\ln 1.001}{1.001^t}.$$

Proof. For $i\in[n], t\geq\frac{\ln 1549}{\ln 1.001}$, according to Claim 19.4.8, $\Pr[y_i\in(1.001^t,1.001^{t+1}]] \geq 0.9995/\pi\cdot\ln(1.0001)/1.001^t$. Thus, $\mathbb{E}[|L_t^+|] = \mathbb{E}[|L_t^-|] = n\cdot 0.9995/\pi\cdot\ln(1.0001)/1.001^t$.

Since $t \leq \frac{0.9999 \ln n}{\ln 1.001}$, $1.001^t \leq n^{0.9999}$, we have $\mathbb{E}[|L_t^+|] = \mathbb{E}[|L_t^-|] \geq n^{\Theta(1)}$. By applying a Chernoff bound,

$$\Pr[|L_t^+| > 0.999n/\pi \cdot \ln(1.0001)/1.001^t] \geq 1 - 1/2^{n^{\Theta(1)}}.$$

Similarly, we have

$$\Pr[|L_t^-| > 0.999n/\pi \cdot \ln(1.0001)/1.001^t] \geq 1 - 1/2^{n^{\Theta(1)}}.$$

By taking a union bound over all the L_t^+ and L_t^-, we complete the proof. □

Lemma 19.4.13 (The contribution from y_i when Δ_i and y_i have the same sign)**.** *Let $u = \eta \cdot \mathbf{1} \in \mathbb{R}^n$ where $\eta \in \mathbb{R}$ is an arbitrary real number. Let $y \in \mathbb{R}^n$ be a random vector with $y_i \sim C(0, \beta)$ independently for some $\beta > 0$. Let $\Delta \in \mathbb{R}^n$ be a random vector with $\Delta_i \sim C(0, 1)$ independently. With probability at least $1 - 1/2^{n^{\Theta(1)}}$,*

$$\sum_{i \,:\, \text{sign}((u+y)_i)=\text{sign}(\Delta_i) \text{ and } |\Delta_i| \leq n^{0.9999}} |(u+y)_i| \geq \beta \cdot \frac{0.997}{\pi} n \ln n.$$

Proof. For all $t \in (\frac{\ln 1549}{\ln 1.001}, \frac{0.9999 \ln n}{\ln 1.001}) \cap \mathbb{N}$, define

$$L_t^- = \{i \in [n] \mid -y_i \in (\beta \cdot 1.001^t, \beta \cdot 1.001^{t+1}]\},$$
$$L_t^+ = \{i \in [n] \mid +y_i \in (\beta \cdot 1.001^t, \beta \cdot 1.001^{t+1}]\}.$$

Define

$$G = \{i \in [n] \mid \text{sign}((u+y)_i) = \text{sign}(\Delta_i) \text{ and } |\Delta_i| \leq n^{0.9999}\}.$$

Then $\forall i \in [n], \Pr[i \in G] \geq 0.5 - 1/n^{0.9999} \geq 0.4999999999$. Due to Lemma 19.4.12,

$$\min(|L_t^-|, |L_t^+|) \geq 0.999n \cdot \frac{1}{\pi} \frac{\ln 1.001}{1.001^t} \geq n^{\Theta(1)}.$$

By the Chernoff bound and a union bound, with probability at least $1 - 1/2^{n^{\Theta(1)}}$, $\forall t \in (\frac{\ln 1549}{\ln 1.001}, \frac{0.9999 \ln n}{\ln 1.001}) \cap \mathbb{N}$,

$$\min(|L_t^- \cap G|, |L_t^+ \cap G|) \geq 0.499n \cdot \frac{1}{\pi} \frac{\ln 1.001}{1.001^t}. \tag{19.9}$$

Then we have

$$\begin{aligned}
&\sum_{i \in G} |(u+y)_i| \\
&\geq \sum_{t \in (\frac{\ln 1549}{\ln 1.001}, \frac{0.9999 \ln n}{\ln 1.001}) \cap \mathbb{N}} \left(\sum_{i \in L_t^+, i \in G} |y_i + \eta| + \sum_{i \in L_t^-, i \in G} |-y_i - \eta| \right) \\
&\geq \sum_{t \in (\frac{\ln 1549}{\ln 1.001}, \frac{0.9999 \ln n}{\ln 1.001}) \cap \mathbb{N}} 0.499n \cdot \frac{1}{\pi} \frac{\ln 1.001}{1.001^t} \cdot 2 \cdot 1.001^t \cdot \beta \\
&\geq \beta \cdot \frac{0.997}{\pi} n \ln n
\end{aligned}$$

The second inequality follows by Equation (19.9) and the triangle inequality, i.e., $\forall a, b, c \in \mathbb{R}, |a+c| + |b-c| \geq |a+b|$. □

19.4.7 Cost from the Sign-Disagreement Part of the Small-Entry Part

Lemma 19.4.14. *Given a vector $y \in \mathbb{R}^n$ and a random vector $\Delta \in \mathbb{R}^n$ with $\Delta_i \sim C(0,1)$ independently, with probability at least $1 - 1/2^{n^{\Theta(1)}}$,*

$$\sum_{i \ : \ \text{sign}(y_i) \neq \text{sign}(\Delta_i) \ \text{ and } \ |\Delta_i| < n^{0.9999}} |y_i + \Delta_i| > \frac{0.03}{\pi} n \ln n.$$

Proof. For $t \in [0, \frac{0.9999 \ln n}{\ln 4}) \cap \mathbb{N}$ define

$$L_t = \{i \in [n] \mid \text{sign}(y_i) \neq \text{sign}(\Delta_i), |\Delta_i| \in (4^t, 4^{t+1}], |\Delta_i| \notin [|y_i| - 4^t, |y_i| + 4^t]\}.$$

$\forall x \geq 1, y > 0$, we have

$$\begin{aligned}
&\Pr_{X \sim C(0,1)}[|X| \in (x, 4x], |X| \notin [y - x, y + x]] \\
\geq &\Pr_{X \sim C(0,1)}[|X| \in (3x, 4x]] \\
= &\frac{2}{\pi} \cdot (\tan^{-1}(4x) - \tan^{-1}(3x)) \\
\geq &\frac{0.1}{\pi} \cdot \frac{\ln(4)}{x}
\end{aligned}$$

Thus, $\forall i \in [n], t \in [0, \frac{0.9999 \ln n}{\ln 4}) \cap \mathbb{N}$,

$$\Pr[i \in L_t] \geq \frac{0.05}{\pi} \cdot \frac{\ln(4)}{4^t}.$$

Thus, $\forall t \in [0, \frac{0.9999 \ln n}{\ln 4}) \cap \mathbb{N}$,

$$\mathbb{E}[|L_t|] \geq 0.05n/\pi \cdot \ln(4)/4^t \geq n^{\Theta(1)}.$$

By a Chernoff bound and a union bound, with probability at least $1 - 1/2^{n^{\Theta(1)}}$ $\forall t \in [0, \frac{0.9999 \ln n}{\ln 4}) \cap \mathbb{N}$,

$$|L_t| \geq 0.04n/\pi \cdot \ln(4)/4^t.$$

Thus, we have, with probability at least $1 - 1/2^{n^{\Theta(1)}}$,

$$\begin{aligned}
&\sum_{i \,:\, \text{sign}(y_i) \neq \text{sign}(\Delta_i) \text{ and } |\Delta_i| < n^{0.9999}} |y_i + \Delta_i| \\
\geq &\sum_{t \in [0, \frac{0.9999 \ln n}{\ln 4}) \cap \mathbb{N}} |L_t| \cdot 4^t \\
\geq &\frac{0.03}{\pi} n \ln n.
\end{aligned}$$

□

19.4.8 Overall Cost of the Small-Entry Part

Lemma 19.4.15 (For each)**.** *Let $u = \eta \cdot \mathbf{1} \in \mathbb{R}^n$ where $\eta \in \mathbb{R}$ is an arbitrary real number. Let $\alpha \in \mathbb{R}^d$ where $\|\alpha\|_1 \geq 1 - 10^{-20}$. Let $\Delta \in \mathbb{R}^{n \times (d+1)}$ and $\forall (i,j) \in [n] \times [d+1], \Delta_{i,j} \sim C(0,1)$ are i.i.d. standard Cauchy random variables. Then with probability at least $1 - 1/2^{n^{\Theta(1)}}$,*

$$\sum_{j \in [n], |\Delta_{j,d+1}| < n^{0.9999}} |(u + \Delta_{d+1} - (u\mathbf{1}^\top + \Delta_{[d]})\alpha)_j| \geq \frac{2.025}{\pi} n \ln n.$$

Proof. Let G_1 and G_2 be defined as

$$G_1 = \{j \in [n] \mid |\Delta_{j,d+1}| < n^{0.9999}, \mathrm{sign}((u(1 - \mathbf{1}^\top \alpha) - \Delta_{[d]}\alpha)_j) = \mathrm{sign}(\Delta_{d+1})_j)\},$$
$$G_2 = \{j \in [n] \mid |\Delta_{j,d+1}| < n^{0.9999}, \mathrm{sign}((u(1 - \mathbf{1}^\top \alpha) - \Delta_{[d]}\alpha)_j) \neq \mathrm{sign}(\Delta_{d+1})_j)\}.$$

Notice that $\Delta_{[d]}\alpha$ is a random vector with each entry independently drawn from $C(0, \|\alpha\|_1)$. Then with probability at least $1 - 1/2^{n^{\Theta(1)}}$,

$$\begin{aligned}
& \sum_{j \in [n], |\Delta_{j,d+1}| < n^{0.9999}} |(u + \Delta_{d+1} - (u\mathbf{1}^\top + \Delta_{[d]})\alpha)_j| \\
= & \sum_{j \in [n], |\Delta_{j,d+1}| < n^{0.9999}} |(u(1 - \mathbf{1}^\top \alpha) - \Delta_{[d]}\alpha + \Delta_{d+1})_j| \\
= & \sum_{j \in G_1} |(u(1 - \mathbf{1}^\top \alpha) - \Delta_{[d]}\alpha + \Delta_{d+1})_j| + \sum_{j \in G_2} |(u(1 - \mathbf{1}^\top \alpha) - \Delta_{[d]}\alpha + \Delta_{d+1})_j| \\
= & \sum_{j \in G_1} |(u(1 - \mathbf{1}^\top \alpha) - \Delta_{[d]}\alpha)_j| + \sum_{j \in G_1} |(\Delta_{d+1})_j| + \sum_{j \in G_2} |(u(1 - \mathbf{1}^\top \alpha) - \Delta_{[d]}\alpha + \Delta_{d+1})_j| \\
\geq & \|\alpha\|_1 \cdot \frac{0.997}{\pi} \cdot n \ln n + \frac{0.9998}{\pi} n \ln n + \frac{0.03}{\pi} n \ln n \\
\geq & \frac{2.025}{\pi} n \ln n
\end{aligned}$$

The first inequality follows by Lemma 19.4.13, Lemma 19.4.11 and Lemma 19.4.14. The second inequality follows by $\|\alpha\|_1 \geq 1 - 10^{-20}$. □

Lemma 19.4.16 (For all)**.** *Let $c > 0, c_0 > 0$ be two arbitrary constants. Let $u = \eta \cdot \mathbf{1} \in \mathbb{R}^n$ where $\eta \in \mathbb{R}$ satisfies $|\eta| \le n^{c_0}$. Consider a random matrix $\Delta \in \mathbb{R}^{n\times(d+1)}$ with $d = n^{o(1)}$ and $\forall (i,j) \in [n]\times[d+1], \Delta_{i,j} \sim C(0,1)$ are i.i.d. standard Cauchy random variables. Conditioned on $\|\Delta\|_1 \le n^3$, with probability at least $1 - 1/2^{n^{\Theta(1)}}$, $\forall \alpha \in \mathbb{R}^d$ with $1 - 10^{-20} \le \|\alpha\|_1 \le n^c$,*

$$\sum_{j\in[n],|\Delta_{j,d+1}|<n^{0.9999}} |(u + \Delta_{d+1} - (u\mathbf{1}^\top + \Delta_{[d]})\alpha)_j| \ge \frac{2.024}{\pi} n \ln n.$$

Proof. Let $\mathcal{N}$ be a set of points:

$$\mathcal{N} = \left\{ \alpha \in \mathbb{R}^d \mid 1 - 10^{-20} \le \|\alpha\|_1 \le n^c \text{ and } \exists q \in \mathbb{Z}^d, \text{ such that } \alpha = q/n^{c+c_0+1000} \right\}.$$

Since $d = n^{o(1)}$, we have $|\mathcal{N}| \le (n^{2c+c_0+2000})^d = 2^{n^{o(1)}}$. By Lemma 19.4.15 and a union bound, with probability at least $1 - 1/2^{n^{\Theta(1)}} \cdot |\mathcal{N}| \ge 1 - 1/2^{n^{\Theta(1)}}$, $\forall \alpha \in \mathcal{N}$, we have

$$\sum_{j\in[n],|\Delta_{j,d+1}|<n^{0.9999}} |(u + \Delta_{d+1} - (u\mathbf{1}^\top + \Delta_{[d]})\alpha)_j| \ge \frac{2.025}{\pi} n \ln n.$$

Due to the construction of $\mathcal{N}$, we have $\forall \alpha \in \mathbb{R}^d$ with $1 - 10^{-20} \le \|\alpha\|_1 \le n^c$, $\exists \alpha' \in \mathcal{N}$ such that $\|\alpha - \alpha'\|_\infty \le 1/n^{c+c_0+1000}$. Let $\gamma = \alpha - \alpha'$. Then

$$\begin{aligned}
& \sum_{j\in[n],|\Delta_{j,d+1}|<n^{0.9999}} |(u + \Delta_{d+1} - (u\mathbf{1}^\top + \Delta_{[d]})\alpha)_j| \\
= & \sum_{j\in[n],|\Delta_{j,d+1}|<n^{0.9999}} |(u + \Delta_{d+1} - (u\mathbf{1}^\top + \Delta_{[d]})(\alpha' + \gamma))_j| \\
\ge & \sum_{j\in[n],|\Delta_{j,d+1}|<n^{0.9999}} |(u + \Delta_{d+1} - (u\mathbf{1}^\top + \Delta_{[d]})\alpha')_j| - \sum_{j\in[n],|\Delta_{j,d+1}|<n^{0.9999}} |((u\mathbf{1}^\top + \Delta_{[d]})\gamma)_j| \\
\ge & \sum_{j\in[n],|\Delta_{j,d+1}|<n^{0.9999}} |(u + \Delta_{d+1} - (u\mathbf{1}^\top + \Delta_{[d]})\alpha')_j| - \|(u\mathbf{1}^\top + \Delta_{[d]})\gamma\|_1 \\
\ge & \frac{2.025}{\pi} n \ln n - 1/n^{500} \\
\ge & \frac{2.024}{\pi} n \ln n
\end{aligned}$$

The first equality follows from $\alpha = \alpha' + \gamma$. The first inequality follows by the triangle inequality. The third inequality follows from $\|\gamma\|_1 \le 1/n^{c+c_0+800}, \|u\mathbf{1}^\top\|_1 \le n^{c_0+10}, \|\Delta\|_1 \le n^3$, and $\forall \alpha' \in \mathcal{N}$,

$$\sum_{j\in[n],|\Delta_{j,d+1}|<n^{0.9999}} |(u + \Delta_{d+1} - (u\mathbf{1}^\top + \Delta_{[d]})\alpha')_j| \ge \frac{2.025}{\pi} n \ln n.$$

□

19.4.9 Main result

Theorem 19.4.17 (Formal version of Theorem 19.1.2)**.** *Let $n > 0$ be sufficiently large. Let $A = \eta \cdot \mathbf{1} \cdot \mathbf{1}^\top + \Delta \in \mathbb{R}^{n\times n}$ be a random matrix where $\eta = n^{c_0}$ for some sufficiently large constant c_0, and $\forall i, j \in [n], \Delta_{i,j} \sim C(0,1)$ are i.i.d. standard Cauchy random variables. Let $r = n^{o(1)}$. Then with probability at least $1 - O(1/\log\log n)$, $\forall S \subset [n]$ with $|S| = r$,*

$$\min_{X\in\mathbb{R}^{r\times n}} \|A_S X - A\|_1 \ge 1.002\|\Delta\|_1$$

Proof. We first argue that for a fixed set S, conditioned on $\|\Delta\|_1 \le 100n^2 \ln n$, with probability at least $1 - 1/2^{n^{\Theta(1)}}$,

$$\min_{X\in\mathbb{R}^{r\times n}} \|A_S X - A\|_1 \ge 1.002\|\Delta\|_1.$$

Then we can take a union bound over the at most $n^r = 2^{n^{o(1)}}$ possible choices of S. It suffices to show for a fixed set S, $\min_{X\in\mathbb{R}^{r\times n}} \|A_S X - A\|_1$ is not small.

Without loss of generality, let $S = [r]$, and we want to argue the cost

$$\min_{X\in\mathbb{R}^{r\times n}} \|A_S X - A\|_1 \ge \min_{X\in\mathbb{R}^{r\times n}} \|A_S X_{[n]\setminus S} - A_{[n]\setminus S}\|_1 \ge 1.002\|\Delta\|_1.$$

Due to Lemma 19.4.2, with probability at least $1 - O(1/\log\log n)$,

$$\|\Delta\|_1 \leq 4.0002/\pi \cdot n^2 \ln n.$$

Now, we can condition on $\|\Delta\|_1 \leq 4.0002/\pi \cdot n^2 \ln n$.

Consider $j \in [n] \setminus S$. Due to Lemma 19.4.5, with probability at least $1 - (1/n)^{\Theta(n)}$, for all $X_j \in \mathbb{R}^r$ with $\|X_j\|_1 \geq n^c$ for some constant $c > 0$, we have

$$\|A_S X_j - A_j\|_1 = \|(\eta \cdot \mathbf{1} \cdot \mathbf{1}^\top + [\Delta_S \ \Delta_j])[X_j^\top \ -1]^\top\|_1 \geq 0.9n^3.$$

By taking a union bound over all $j \in [n] \setminus S$, with probability at least $1 - (1/n)^{\Theta(n)}$, for all $X \in \mathbb{R}^{r \times n}$ with $\exists j \in [n] \setminus S, \|X_j\|_1 \geq n^c$, we have

$$\|A_S X - A\|_1 \geq 0.9n^3.$$

Thus, we only need to consider the case $\forall j \in [n] \setminus S, \|X_j\|_1 \leq n^c$. Notice that we condition on $\|\Delta\|_1 \leq 4.0002/\pi \cdot n^2 \ln n$. By Fact 19.4.1, we have that if $\|X_j\|_1 \leq n^c$ and $|1 - \mathbf{1}^\top X_j| > 1 - 10^{-20}$, then

$$\|A_S X - A\|_1 \geq \|A_S X_j - A_j\|_1 > n^3.$$

Thus, we only need to consider the case $\forall j \in [n] \setminus S, \|X_j\|_1 \leq n^c, |1 - \mathbf{1}^\top X_j| \leq 1 - 10^{-20}$. $\forall X \in \mathbb{R}^{r \times n}$ with $\forall j \in [n] \setminus S, \|X_j\|_1 \leq n^c, |1 - \mathbf{1}^\top X_j| \leq 1 - 10^{-20}$, if $\|A_S X_{[n] \setminus S} - A_{[n] \setminus S}\|_1 \leq$

$4n^2 \ln n$, then

$$
\begin{aligned}
&\|A_S X_{[n]\setminus S} - A_{[n]\setminus S}\|_1 \\
=\ &\|(\eta \cdot \mathbf{1}\cdot\mathbf{1}^\top + \Delta_S)X_{[n]\setminus S} - (\eta\cdot\mathbf{1}\cdot\mathbf{1}^\top + \Delta_{[n]\setminus S})\|_1 \\
\geq\ & \sum_{i\in[n], j\in[n]\setminus S, |\Delta_{i,j}|\geq n^{1.0002}} |(((\eta\cdot\mathbf{1}\cdot\mathbf{1}^\top + \Delta_S)X_{[n]\setminus S} - \eta\cdot\mathbf{1}\cdot\mathbf{1}^\top) - \Delta_{[n]\setminus S})_{i,j}| \\
&+ \sum_{i\in[n], j\in[n]\setminus S, |\Delta_{i,j}|<n^{0.9999}} |((\eta\cdot\mathbf{1}\cdot\mathbf{1}^\top + \Delta_S)X_{[n]\setminus S} - (\eta\cdot\mathbf{1}\cdot\mathbf{1}^\top + \Delta_{[n]\setminus S}))_{i,j}| \\
\geq\ & \frac{1.996}{\pi}\cdot n^2\ln n + \sum_{i\in[n], j\in[n]\setminus S, |\Delta_{i,j}|<n^{0.9999}} |((\eta\cdot\mathbf{1}\cdot\mathbf{1}^\top + \Delta_S)X_{[n]\setminus S} - (\eta\cdot\mathbf{1}\cdot\mathbf{1}^\top + \Delta_{[n]\setminus S}))_{i,j}| \\
=\ & \frac{1.996}{\pi}\cdot n^2\ln n + \sum_{j\in[n]\setminus S}\sum_{i\in[n], |\Delta_{i,j}|<n^{0.9999}} |((\eta\cdot\mathbf{1}\cdot\mathbf{1}^\top + \Delta_S)X_j - \eta\cdot\mathbf{1} - \Delta_j)_i| \\
\geq\ & \frac{1.996}{\pi}\cdot n^2\ln n + \sum_{j\in[n]\setminus S}\frac{2.024}{\pi} n\ln n \\
\geq\ & \frac{1.996}{\pi}\cdot n^2\ln n + \frac{2.023}{\pi} n^2\ln n \\
\geq\ & \frac{4.01}{\pi}\cdot n^2\ln n
\end{aligned}
$$

holds with probability at least $1 - 1/2^{n^{\Theta(1)}}$. The first equality follows by the definition of A. The first inequality follows by the partition by $|\Delta_{i,j}|$. Notice that $[\mathbf{1}\ \Delta_S]$ has rank at most $r+1 = n^{o(1)}$. Then, due to Lemma 19.4.10, and the condition $\|A_S X_{[n]\setminus S} - A_{[n]\setminus S}\|_1 \leq 4n^2\ln n$, the second inequality holds with probability at least $1 - 1/2^{n^{\Theta(1)}}$. The second equality follows by grouping the cost by each column. The third inequality holds with probability at least $1 - 1/2^{n^{\Theta(1)}}$ by Lemma 19.4.16, and a union bound over all the columns in $[n]\setminus S$. The fourth inequality follows by $n - r = n - n^{o(1)} \geq (1 - 10^{-100})n$.

Thus, conditioned on $\|\Delta\|_1 \leq 4.0002/\pi \cdot n^2\ln n$, with probability at least $1 - 1/2^{n^{\Theta(1)}}$,

we have

$$\min_{X\in\mathbb{R}^{r\times n}} \|A_S X - A\|_1 \geq \frac{4.02}{\pi}\cdot n^2 \ln n.$$

By taking a union bound over all the $\binom{n}{r} = 2^{n^{o(1)}}$ choices of S, we have that conditioned on $\|\Delta\|_1 \leq \frac{4.0002}{\pi} n^2 \ln n$, with probability at least $1 - 1/2^{n^{\Theta(1)}}$, $\forall S \subset [n]$ with $|S| = r = n^{o(1)}$, $\min_{X\in\mathbb{R}^{r\times n}} \|A_S X - A\|_1 \geq \frac{4.02}{\pi}\cdot n^2 \ln n$. Since $4.01/4.0002 > 1.002$,

$$\min_{X\in\mathbb{R}^{r\times n}} \|A_S X - A\|_1 \geq 1.002\|\Delta\|_1.$$

Since $\|\Delta\|_1 \leq \frac{4.0002}{\pi} n^2 \ln n$ happens with probability at least $1 - O(1/\log\log n)$, this completes the proof. □

Chapter 20

Towards a Zero-One Law for Low Rank Approximation

There are a number of approximation algorithms for NP-hard versions of low rank approximation, such as finding a rank-k matrix B minimizing the sum of absolute values of differences to a given n-by-n matrix A, $\min_{\text{rank-}k\ B} \|A - B\|_1$, or more generally finding a rank-k matrix B which minimizes the sum of p-th powers of absolute values of differences, $\min_{\text{rank-}k\ B} \|A - B\|_p^p$. Many of these algorithms are linear time columns subset selection algorithms, returning a subset of $\text{poly}(k \log n)$ columns whose cost is no more than a $\text{poly}(k)$ factor larger than the cost of the best rank-k matrix. The above error measures are special cases of the following general entrywise low rank approximation problem: given an arbitrary function $g : \mathbb{R} \to \mathbb{R}_{\geq 0}$, find a rank-$k$ matrix B which minimizes $\|A-B\|_g = \sum_{i,j} g(A_{i,j}-B_{i,j})$. A natural question is which functions g admit efficient approximation algorithms? Indeed, this is a central question of recent work studying generalized low rank models. In this work we give approximation algorithms for *every* function g which is approximately monotone and satisfies an approximate triangle inequality, and we show both of these conditions are necessary. Further, our algorithm is efficient if the function g admits an efficient approximate regression algorithm. Our approximation algorithms handle functions which are not even scale-invariant, such as the Huber loss function, which we show have very different structural properties than ℓ_p-norms, e.g., one can show the lack of scale-invariance causes any column subset selection algorithm to provably require a $\sqrt{\log n}$ factor larger number of columns

than ℓ_p-norms; nevertheless we design the first efficient column subset selection algorithms for such error measures.

20.1 Introduction

A well-studied problem in machine learning and numerical linear algebra, with applications to recommendation systems, text mining, and computer vision, is that of computing a low-rank approximation of a matrix. Such approximations reveal low-dimensional structure, provide a compact way of storing a matrix, and can quickly be applied to a vector.

A commonly used version of the problem is to compute a near optimal low-rank approximation with respect to the Frobenius norm. That is, given an $n \times n$ input matrix A and an accuracy parameter $\epsilon > 0$, output a rank-k matrix B with large probability so that $\|A - B\|_F^2 \leq (1+\epsilon)\|A - A_k\|_F^2$, where for a matrix C, $\|C\|_F^2 = \sum_{i,j} C_{i,j}^2$ is its squared Frobenius norm, and $A_k = \text{argmin}_{\text{rank-}k\ B}\|A - B\|_F$. A_k can be computed exactly using the singular value decomposition (SVD), but takes $O(n^3)$ time in practice and n^ω time in theory, where $\omega \approx 2.373$ is the exponent of matrix multiplication [Str69, CW87, Wil12, LG14].

Sárlos [Sar06] showed how to achieve the above guarantee with constant probability in $\widetilde{O}(\text{nnz}(A) \cdot k/\epsilon) + n \cdot \text{poly}(k/\epsilon)$ time, where $\text{nnz}(A)$ denotes the number of non-zero entries of A. This was improved in [CW13, MM13, NN13a, BDN15, Coh16a] using sparse random projections in $O(\text{nnz}(A)) + n \cdot \text{poly}(k/\epsilon)$ time. Large sparse datasets in recommendation systems are common, such as the Bookcrossing ($100K \times 300K$ with 10^6 observations) [ZMKL05] and Yelp datasets ($40K \times 10K$ with 10^5 observations) [Yel14], and this is a substantial improvement over the SVD.

Robust Low Rank Approximation. To understand the role of the Frobenius norm in the algorithms above, we recall a standard motivation for this error measure. Suppose one has n data points in a k-dimensional subspace of $\mathbb{R}^d$, where $k \ll d$. We can write these points

as the rows of an $n \times d$ matrix A^* which has rank k. The matrix A^* is often called the *ground truth matrix*. In a number of settings, due to measurement noise or other kinds of noise, we only observe the matrix $A = A^* + \Delta$, where each entry of the *noise matrix* $\Delta \in \mathbb{R}^{n \times n}$ is an i.i.d. random variable from a certain mean-zero noise distribution $\mathcal{D}$. One method for approximately recovering A^* from A is maximum likelihood estimation. Here one tries to find a matrix B maximizing the log-likelihood: $\max_{\text{rank-}k\ B} \sum_{i,j} \log p(A_{i,j} - B_{i,j})$, where $p(\cdot)$ is the probability density function of the underlying noise distribution $\mathcal{D}$. For example, when the noise distribution is Gaussian with mean zero and variance σ^2, denoted by $N(0, \sigma^2)$, then the optimization problem is $\max_{\text{rank-}k\ B} \sum_{i,j} \left(\log(1/\sqrt{2\pi\sigma^2}) - (A_{i,j} - B_{i,j})^2/(2\sigma^2) \right)$, which is equivalent to solving the Frobenius norm loss low rank approximation problem defined above.

The Frobenius norm loss, while having nice statistical properties for Gaussian noise, is well-known to be sensitive to outliers. Applying the same maximum likelihood framework above to other kinds of noise distributions results in minimizing other kinds of loss functions. In general, if the density function of the underlying noise $\mathcal{D}$ is $p(z) = c \cdot e^{-g(z)}$, where c is a normalization constant, then the maximum likelihood estimation problem for this noise distribution becomes the following generalized entry-wise loss low rank approximation problem: $\min_{\text{rank-}k\ B} \sum_{i,j} g(A_{i,j} - B_{i,j}) = \min_{\text{rank-}k\ B} \|A - B\|_g$, which is a central topic of recent work on *generalized low-rank models* [UHZ+16]. For example, when the noise is Laplacian, the entrywise ℓ_1 loss is the maximum likelihood estimation, which is also robust to sparse outliers. A natural setting is when the noise is a mixture of small Gaussian noise and sparse outliers; this noise distribution is referred to as the *Huber density*. In this case the Huber loss function gives the maximum likelihood estimate [UHZ+16], where the Huber

function [Hub64] is defined to be: $g(x) = x^2/(2\tau)$ if $|x| < \tau/2$, and $g(x) = |x| - \tau/2$ if $|x| \geq \tau$. Another nice property of the Huber error measure is that it is differentiable everywhere, unlike the ℓ_1-norm, yet still enjoys the robustness properties as one moves away from the origin, making it less sensitive to outliers than the ℓ_2-norm. There are many other kinds of loss functions, known as M-estimators [Zha97], which are widely used as loss functions in robust statistics [HRRS11].

Although several specific cases have been studied, such as entry-wise ℓ_p loss [CLMW11, SWZ17, CGK+17a, BKW17, BBB+19a], weighted entry-wise ℓ_2 loss [RSW16], and cascaded $\ell_p(\ell_2)$ loss [DVTV09, CW15a], the landscape of general entry-wise loss functions remains elusive. There are no results known for any loss function which is not scale-invariant, much less any kind of characterization of which loss functions admit efficient algorithms. This is despite the importance of these loss functions; we refer the reader to [UHZ+16] for a survey of generalized low rank models. This motivates the main question in our work:

Question 20.1.1 (General Loss Functions)**.** *For a given approximation factor $\alpha > 1$, which functions g allow for efficient low-rank approximation algorithms? Formally, given an $n \times d$ matrix A, can we find a* rank-k *matrix B for which $\|A - B\|_g \leq \alpha \min_{\text{rank}-k\ B'} \|A - B'\|_g$, where for a matrix C, $\|C\|_g = \sum_{i \in [n], j \in [d]} g(C_{i,j})$? What if we also allow B to have rank* $\text{poly}(k \log n)$*?*

For Question 20.1.1, one has $g(x) = |x|^p$ for p-norms, and note the Huber loss function also fits into this framework. Allowing B to have slightly larger rank than k, namely, $\text{poly}(k \log n)$, is often sufficient for applications as it still allows for the space savings and computational gains outlined above. These are referred to as bicriteria approximations and are the focus of our work.

Notation. Before we present our results, let us briefly introduce the notation. For $n \in \mathbb{Z}_{\geq 0}$, let $[n]$ denote the set $\{1, 2, \cdots, n\}$. Let $A \in \mathbb{R}^{n \times m}$. A_i and A^j denote the i^{th} column and the j^{th} row of A respectively. Let $P \subseteq [m], Q \subseteq [n]$. A_P denotes the matrix which is composed by the columns of A with column indices in P. Similarly, A^Q denotes the matrix composed by the rows of A with row indices in Q. Let S be a set and $s \in \mathbb{Z}_{\geq 0}$. We use $\binom{S}{s}$ to denote the set of all the size-s subsets of S.

20.1.1 Our Results

We give necessary and sufficient conditions for low rank approximation with respect to general error measures. Our algorithm is a column subset selection algorithm, returning a small subset of columns which span a good low rank approximation. Column subset selection has the benefit of preserving sparsity and interpretability, as described above. We describe two properties on the function g that we need to obtain our low rank approximation algorithms, and show that if g does not have either property, then there are matrices for which no small subset of columns spanning a good low rank approximation with respect to the error measure g exists. We make these terms precise in the theorem statements below.

Since we obtain column subset selection algorithms for a wide class of functions, our algorithms must necessarily be bicriteria and have approximation factor at least $\text{poly}(k)$. Indeed, a special case of our class of functions includes entrywise ℓ_1-low rank approximation, for which it was shown in Theorem G.27 of [SWZ17] that any subset of $\text{poly}(k)$ columns incurs an approximation error of at least $k^{\Omega(1)}$. We also show that for the entrywise Huber-low rank approximation, already for $k = 1$, $\sqrt{\log n}$ columns are needed to obtain any constant factor approximation, thus showing that for some of the functions we consider, a dependence

on n in our column subset size is necessary.

We note that previously for almost all such functions, it was not known how to obtain any non-trivial approximation factor with any sublinear number of columns.

20.1.1.1 A Zero-One Law

We first state three general properties, the first two of which are structural properties and are necessary and sufficient for obtaining a good approximation from a small subset of columns. The third property is needed for efficient running time.

Approximate triangle inequality. For $t \in \mathbb{Z}_{>0}$, we say a function $g(x) : \mathbb{R} \to \mathbb{R}_{\geq 0}$ satisfies the $\text{ati}_{g,t}$-approximate triangle inequality if for any $x_1, x_2, \cdots, x_t \in \mathbb{R}$, $g\left(\sum x_i\right) \leq \text{ati}_{g,t} \cdot \sum g(x_i)$.

Monotone property. For any parameter $\text{mon}_g \geq 1$, we say function $g(x) : \mathbb{R} \to \mathbb{R}_{\geq 0}$ is mon_g-monotone if for any $x, y \in \mathbb{R}$ with $0 \leq |x| \leq |y|$, we have $g(x) \leq \text{mon}_g \cdot g(y)$.

Many functions including most M-estimators [Zha97] and the quantile function [KBJ78] satisfy the above two properties. See Table 20.1 for several examples. We refer the reader to the later sections for the necessity of these two properties. Our next property is not structural, but rather states that if the loss function has an efficient regression algorithm, then that suffices to efficiently find a small subset of columns spanning a good low rank approximation.

Regression property. We say function $g(x) : \mathbb{R} \to \mathbb{R}_{\geq 0}$ has the $(\text{reg}_{g,d}, \mathcal{T}_{\text{reg},g,n,d,m})$-regression property if the following holds: given two matrices $A \in \mathbb{R}^{n \times d}$ and $B \in \mathbb{R}^{n \times m}$, for each $i \in [m]$, let OPT_i denote $\min_{x \in \mathbb{R}^d} \|Ax - B_i\|_g$. There is an algorithm that runs in

Table 20.1: Example functions satisfying both structural properties.

	$g(x)$	$\text{ati}_{g,t}$	mon_g
HUBER	$\begin{cases} x^2/2 & \lvert x\rvert \le \tau \\ \tau(\lvert x\rvert - \tau/2) & \lvert x\rvert > \tau \end{cases}$	$O(t)$	1
ℓ_p $(p \ge 1)$	$\lvert x\rvert^p/p$	$O(t^{p-1})$	1
$\ell_1 - \ell_2$	$2(\sqrt{1 + x^2/2} - 1)$	$O(t)$	1
GEMAN-MCCLURE	$x^2/(2 + 2x^2)$	$O(t)$	1
"FAIR"	$\tau^2\left(\lvert x\rvert/\tau - \log(1 + \lvert x\rvert/\tau)\right)$	$O(t)$	1
TUKEY	$\begin{cases} \tau^2/6 \cdot (1 - (1 - (x/\tau)^2)^3) & \lvert x\rvert \le \tau \\ \tau^2/6 & \lvert x\rvert > \tau \end{cases}$	$O(t)$	1
CAUCHY	$\tau^2/2 \cdot \log(1 + (x/\tau)^2)$	$O(t)$	1
QUANTILE $(\tau \in (0,1))$	$\begin{cases} \tau x & x \ge 0 \\ (\tau - 1)x & x < 0 \end{cases}$	1	$\max\left(\frac{\tau}{1-\tau}, \frac{1-\tau}{\tau}\right)$

$\mathcal{T}_{\text{reg},g,n,d,m}$ time and outputs a matrix $X' \in \mathbb{R}^{d \times m}$ such that $\|AX'_i - B_i\|_g \le \text{reg}_{g,d} \cdot \text{OPT}_i, \forall i \in [m]$ and outputs a vector of estimated regression costs $v \in \mathbb{R}^d$ such that $\text{OPT}_i \le v_i \le \text{reg}_{g,d} \cdot \text{OPT}_i, \forall i \in [m]$. The success probability is at least $1 - 1/\operatorname{poly}(nm)$.

Some functions for which regression itself is non-trivial are e.g., the ℓ_0-loss function and Tukey function. The ℓ_0-loss function corresponds to the nearest codeword problem over the reals and has slightly better than an $O(d)$-approximation ([BK02, APY09], see also [BKW17]). For the Tukey function, [CWW19] shows that Tukey regression is NP-hard, and it also gives approximation algorithms. For discussion on regression solvers, we refer the reader to Appendix 20.5.

For any function, as long as the above general three properties hold, we can provide an efficient algorithm, as our following main theorem shows.

Theorem 20.1.2. *Given a matrix $A \in \mathbb{R}^{n \times n}$, let $k \ge 1, k' = 2k + 1$. Let $g : \mathbb{R} \to \mathbb{R}_{\ge 0}$*

denote a function satisfying the $\mathrm{ati}_{g,k'}$*-approximate triangle inequality, the* mon_g*-monotone property , and the* $(\mathrm{reg}_{g,k'}, \mathcal{T}_{\mathrm{reg},g,n,k',n})$*-regression property. Let* $\mathrm{OPT} = \min_{\mathrm{rank}-k\ A'} \|A'-A\|_g$*. There is an algorithm that runs in* $\widetilde{O}(n + \mathcal{T}_{\mathrm{reg},g,n,k',n})$ *time and outputs a set* $S \subseteq [n]$ *with* $|S| = O(k \log n)$ *such that with probability at least* 0.99*,*

$$\min_{X \in \mathbb{R}^{|S| \times n}} \|A_S X - A\|_g \leq \mathrm{ati}_{g,k'} \cdot \mathrm{mon}_g \cdot \mathrm{reg}_{g,k'} \cdot O(k \log k) \cdot \mathrm{OPT}\,.$$

Although the input matrix A in the above statement is a square matrix, it is straightforward to extend the result to the rectangular case. By the above theorem, we can obtain a good subset of columns. To further get a low rank matrix B which is a good low rank approximation to A, it is sufficient to take an additional $\mathcal{T}_{\mathrm{reg},g,n,|S|,n}$ time to solve the regression problem.

20.1.1.2 Lower Bound on the Number of Columns

One may wonder if the $\log n$ blowup in rank is necessary in our theorem. We show some dependence on n is necessary by showing that for the important Huber loss function, at least $\sqrt{\log n}$ columns are required in order to obtain a constant factor approximation for $k = 1$:

Theorem 20.1.3. *Let* $H(x)$ *denote the following function:* $H(x) = \begin{cases} x^2, & \text{if } |x| < 1; \\ |x|, & \text{if } |x| \geq 1. \end{cases}$

For any $n \geq 1$*, there is a matrix* $A \in \mathbb{R}^{n \times n}$ *such that, if we select* $o(\sqrt{\log n})$ *columns to fit the entire matrix, there is no* $O(1)$*-approximation, i.e., for any subset* $S \subseteq [n]$ *with* $|S| = o(\sqrt{\log n})$*,*

$$\min_{X \in \mathbb{R}^{|S| \times n}} \|A_S X - A\|_H \geq \omega(1) \cdot \min_{\mathrm{rank}-1\ A'} \|A' - A\|_H.$$

Notice that the above function $H(x)$ is always a constant approximation to the Huber function (see Table 20.1) with $\tau = 1$. Thus, the hardness also holds for the Huber function. For more discussion on our lower bound, we refer the reader to Appendix 20.6.

20.1.2 Overview of our Approach and Related Work

Low Rank Approximation for General Functions. A natural approach to low rank approximation is "column subset selection", which has been extensively studied in numerical linear algebra [DMM06c, DMM06b, DMM08, BMD09, BDM11, FEGK13, BW14, WS15, SWZ17, SWZ19b]. One can take the column subset selection algorithm for ℓ_p-low rank approximation in [CGK+17a] and try to adapt it to general loss functions. Namely, their argument shows that for any matrix $A \in \mathbb{R}^{n\times n}$ there exists a subset S of k columns of A, denoted by $A_S \in \mathbb{R}^{n\times k}$, for which there exists a $k \times n$ matrix V for which $\|A_S V - A\|_p^p \leq (k+1)^p \min_{\text{rank-}k\ B'} \|A - B'\|_p^p$; we refer the reader to Theorem 3 of [CGK+17a]. Given the existence of such a subset S, a natural next idea is to then sample a set T of k columns of A uniformly at random. It is then likely the case that if we look at a random column A_i, (1) with probability $1/(k+1)$, i is not among the subset S of k columns out of the $k+1$ columns $T \cup \{i\}$ defining the optimal rank-k approximation to the submatrix $A_{T\cup\{i\}}$, and (2) with probability at least $1/2$, the best rank-k approximation to $A_{T\cup\{i\}}$ has cost at most

$$(2(k+1)/n) \cdot \min_{\text{rank-}k\ B'} \|A - B'\|_p^p. \tag{20.1}$$

Indeed, (1) follows from $T \cup \{i\}$ being a uniformly random subset of $k+1$ columns, while (2) follows from a Markov bound. The argument in Theorem 7 of [CGK+17a] is then able to "prune" a $1/(k+1)$ fraction of columns (this can be optimized to a constant fraction) in expectation, by "covering" them with the random set T. Recursing on the remaining columns,

this procedure stops after $k \log n$ iterations, giving a column subset of size $O(k^2 \log n)$ (which can be optimized to $O(k \log n)$) and an $O(k)$-approximation.

The proof in [CGK+17a] of the existence of a subset S of k columns of A spanning a $(k+1)$-approximation above is quite general, and one might suspect it generalizes to a large class of error functions. Suppose, for example, that $k = 1$. The idea there is to write $A = A^* + \Delta$, where $A^* = U \cdot V$ is the optimal rank-1 ℓ_p-low rank approximation to A. One then "normalizes" by the error, defining $\widetilde{A}_i^* = A_i^*/\|\Delta_i\|_p$ and letting s be such that $\|\widetilde{A}_s^*\|_p$ is largest. The rank-1 subset S is then just A_s. Note that since $\widetilde{A}^*$ has rank-1 and $\|\widetilde{A}_s^*\|_p$ is largest, one can write $\widetilde{A}_j^*$ for every $j \neq s$ as $\alpha_j \cdot \widetilde{A}_s^*$ for $|\alpha_j| \leq 1$. The fact that $|\alpha_j| \leq 1$ is crucial; indeed, consider what happens when we try to "approximate" A_j by $A_s \cdot \frac{\alpha_j \|\Delta_j\|_p}{\|\Delta_s\|_p}$. Then $\|A_j - A_s \alpha_j \|\Delta_j\|_p/\|\Delta_s\|_p\|_p \leq \|A_j - A_j^*\|_p + \left\|A_j^* - A_s \alpha_j \|\Delta_j\|_p/\|\Delta_s\|_p\right\|_p = \|\Delta_j\|_p + \left\|A_j^* - (A_s^* + \Delta_s)\alpha_j \|\Delta_j\|_p/\|\Delta_s\|_p\right\|_p = \|\Delta_j\|_p + \|\Delta_s \alpha_j \|\Delta_j\|_p/\|\Delta_s\|_p\|_p$, and since the p-norm is monotonically increasing and $\alpha_j \leq 1$, the latter is at most $\|\Delta_j\|_p + \|\Delta_s \frac{\|\Delta_j\|_p}{\|\Delta_s\|_p}\|_p$. So far, all we have used about the p-norm is the monotone increasing property, so one could hope that the argument could be generalized to a much wider class of functions.

However, at this point the proof uses that the p-norm has *scale-invariance*, and so $\|\Delta_s \frac{\|\Delta_j\|_p}{\|\Delta_s\|_p}\|_p = \|\Delta_j\|_p \cdot \|\frac{\Delta_s}{\|\Delta_s\|_p}\|_p = \|\Delta_j\|_p$, and it follows that $\|A_j - A_s \frac{\alpha_j \|\Delta_j\|_p}{\|\Delta_s\|_p}\|_p \leq 2\|\Delta_j\|_p$, giving an overall 2-approximation (recall $k = 1$). But what would happen for a general, not necessarily scale-invariant function g? We need to bound $\|\Delta_s \frac{\|\Delta_j\|_g}{\|\Delta_s\|_g}\|_g$. If we could bound this by $O(\|\Delta_j\|_g)$, we would obtain the same conclusion as before, up to constant factors. Consider, though, the "reverse Huber function": $g(x) = x^2$ if $x \geq 1$ and $g(x) = |x|$ for $x \leq 1$. Suppose that Δ_s and Δ_j were just 1-dimensional vectors, i.e., real numbers, so we need to bound $g(\Delta_s g(\Delta_j)/g(\Delta_s))$ by $O(g(\Delta_j))$. Suppose $\Delta_s = 1$. Then $g(\Delta_s) = 1$ and

$g(\Delta_s g(\Delta_j)/g(\Delta_s)) = g(g(\Delta_j))$ and if $\Delta_j = n$, then $g(g(\Delta_j)) = n^4 = g(\Delta_j)^2$, much larger than the $O(g(\Delta_j))$ we were aiming for.

Maybe the analysis can be slightly changed to correct for these normalization issues? This is not the case, as we show that unlike for ℓ_p-low rank approximation, for the reverse Huber function *there is no subset of* 2 *columns of* A *obtaining better than an* $n^{1/4}$*-approximation factor*. (See Section 20.6.2 for more details). Further, the lack of scale invariance not only breaks the argument in [CGK+17a], it shows that combinatorially such functions g behave very differently than ℓ_p-norms. We show more generally there exist functions, in particular the Huber function, for which one needs to choose $\Omega(\sqrt{\log n})$ columns to obtain a constant factor approximation; we describe this more below. Perhaps more surprisingly, we show a subset of $O(\log n)$ columns suffice to obtain a constant factor approximation to the best rank-1 approximation for any function $g(x)$ which is approximately monotone and has the approximate triangle inequality, the latter implying for any constant $C > 0$ and any $x \in \mathbb{R}_{\geq 0}$, $g(Cx) = O(g(x))$. For $k > 1$, these conditions become: (1) $g(x)$ is monotone non-decreasing in x, (2) $g(x)$ is within a poly(k) factor of $g(-x)$, and (3) for any real number $x \in \mathbb{R}^{\geq 0}$, $g(O(kx)) \leq \text{poly}(k) \cdot g(x)$. We show it is possible to obtain an $O(k^2 \log k)$ approximation with $O(k \log n)$ columns. We give the intuition and main lemma statements for our result in Section 20.2, deferring proofs to the supplementary material.

Even for ℓ_p-low rank approximation, our algorithms slightly improve and correct a minor error in [CGK+17a] which claims in Theorem 7 an $O(k)$-approximation with $O(k \log n)$ columns for ℓ_p-low rank approximation. However, their algorithm actually gives an $O(k \log n)$-approximation with $O(k \log n)$ columns. In [CGK+17a] it was argued that one expects to pay a cost of $O(k/n) \cdot \min_{\text{rank-}k\ B'} \|A - B'\|_p^p$ per column as in (20.1), and since each column is only

counted in one iteration, summing over the columns gives $O(k) \cdot \min_{\text{rank-}k\ B'} \|A - B'\|_p$ total cost. The issue is that the value of n is changing in each iteration, so if in the i-th iteration it is n_i, then we could pay $n_i \cdot O(k/n_i) \cdot \min_{\text{rank-}k\ B'} \|A - B'\|_p = O(k) \cdot \min_{\text{rank-}k\ B'} \|A - B'\|_p$ in each of $O(\log n)$ iterations, giving $O(k \log n)$ approximation ratio. In contrast, our algorithm achieves an $O(k \log k)$ approximation ratio for ℓ_p-low rank approximation as a special case, which gives the first $O(1)$ approximation in nearly linear time for any constant k for ℓ_p norms. Our analysis is finer in that we show not only do we expect to pay a cost of $O(k/n_i) \cdot \min_{\text{rank-}k\ B'} \|A - B'\|_p^p$ per column in iteration i, we pay $O(k/n_i)$ times the cost of the best rank-k approximation to A *after the most costly* n/k columns have been removed; thus we pay $O(k/n_i)$ times a *residual cost* with the top n/k columns removed. This ultimately implies any column's cost can contribute in at most $O(\log k)$ of $O(\log n)$ recursive calls, replacing an $O(\log n)$ factor with an $O(\log k)$ factor in the approximation ratio. This also gives the first poly(k)-approximation for ℓ_0-low rank approximation, studied in [BKW17], improving the $O(k^2 \log(n/k))$-approximation there to $O(k^2 \log k)$ and giving the first constant approximation for constant k.

Algorithm 20.1 Low Rank Approximation Algorithm for General Functions

procedure GENERALFUNCTIONLOWRANKAPPROX($A \in \mathbb{R}^{n\times n}, k \in \mathbb{Z}_{\geq 1}, g : \mathbb{R} \to \mathbb{R}_{\geq 0}$)
  Initialization: $r \leftarrow O(\log n), T_0 \leftarrow [n]$
  for $i = 1 \to r$ **do**
    for $j = 1 \to \log n$ **do**
      Sample $S_i^{(j)}$ from $\binom{T_{i-1}}{2k}$ uniformly at random
      Solve the $\mathrm{reg}_{g,2k}$-approximate regression $\min_{x\in\mathbb{R}^{2k}} \|A_{S_i^{(j)}} x - A_t\|_g$ for each $t \in T_{i-1} \setminus S_i^{(j)}$, and let $v_{i,t}^{(j)}$ be the $\mathrm{reg}_{g,2k}$-estimated regression cost ▷ See Section 20.1.1.1 for regression property
      $R_i^{(j)} \leftarrow \{t \mid v_{i,t}^{(j)}$ is the bottom $|T_{i-1} \setminus S_i^{(j)}|/20$ largest value in $\{v_{i,t'}^{(j)} \mid t' \in T_{i-1} \setminus S_i^{(j)}\}\}$
      $c_i^{(j)} \leftarrow \sum_{t\in R_i^{(j)}} v_{i,t}^{(j)}$
    end for
    $j^* \leftarrow \arg\min_{j\in[\log n]} \left\{c_i^{(j)}\right\}$
    $S_i \leftarrow S_i^{(j^*)}, R_i \leftarrow R_i^{(j^*)}, T_i \leftarrow T_{i-1} \setminus (S_i \cup R_i)$
  end for
  return $S = T_r \cup \bigcup_{i\in[r]} S_i$
end procedure

20.2 Algorithm for General Loss Low Rank Approximation

Our algorithm is presented in Algorithm 20.1. First, let us briefly analyze the running time. Consider fixed $i \in [r], j \in [\log n]$. Sampling $S_i^{(j)}$ takes $O(k)$ time. Solving $\mathrm{reg}_{g,2k}$-approximate regression $\min_x \|A_{S_i^{(j)}} x - A_t\|_g$ for all $t \in T_{i-1} \setminus S_i^{(j)}$ takes $\mathcal{T}_{\mathrm{reg},g,n,2k,|T_{i-1}\setminus S_i^{(j)}|} \leq \mathcal{T}_{\mathrm{reg},g,n,2k+1,n}$ time. Since finding $|T_{i-1} \setminus S_i^{(j)}|/20$ smallest element can be done in $O(n)$ time, $R_i^{(j)}$ can be computed in $O(n)$ time. Thus the inner loop takes $O(n + \mathcal{T}_{\mathrm{reg},g,n,2k+1,n})$ time. Since $r = O(\log n)$, the total running time over all i, j is $O((n + \mathcal{T}_{\mathrm{reg},g,n,2k+1,n}) \log^2 n)$. In the remainder of the section, we will sketch the proof of the correctness. For the missing proofs, we refer the reader to Appendix 20.3.

20.2.1 Properties of Uniform Column Sampling

Let us first introduce some useful notation. Consider a rank-k matrix $M^* \in \mathbb{R}^{n\times m}$. For a set $H \subseteq [m]$, let $R_{M^*}(H) \subseteq H$ be a set such that

$$R_{M^*}(H) = \arg\max_{P:P\subseteq H} \left\{ \det\left((M^*)_P^Q\right) \;\middle|\; |P| = |Q| = \mathrm{rank}(M^*_H), Q \subseteq [n] \right\},$$

where $\det(C)$ denotes the determinant of a square matrix C. By Cramer's rule, if we use a linear combination of the columns of $M^*_{R_{M^*}(H)}$ to express any column of M^*_H, the absolute value of every fitting coefficient will be at most 1.

Consider an arbitrary matrix $M \in \mathbb{R}^{n\times m}$. We can write $M = M^* + N$, where $M^* \in \mathbb{R}^{n\times m}$ is an arbitrary rank-k matrix, and $N \in \mathbb{R}^{n\times m}$ is the residual matrix. The following lemma shows that, if we randomly choose a subset $H \subseteq [m]$ of $2k$ columns, and we randomly look at another column i, then with constant probability, the absolute values of all the coefficients of using a linear combination of the columns of M^*_H to express M^*_i are at most 1, and furthermore, if we use the same coefficients to use columns of M_H to fit M_i, then the fitting cost is proportional to $\|N_H\|_g + \|N_i\|_g$.

Lemma 20.2.1. *Given a matrix $M \in \mathbb{R}^{n\times m}$ and a parameter $k \geq 1$, let $M^* \in \mathbb{R}^{n\times m}$ be an arbitrary rank-k matrix. Let $N = M - M^*$. Let $H \subseteq [m]$ be a uniformly random subset of $[m]$, and let i denote a uniformly random index sampled from $[m]\backslash H$. Then* (I) $\Pr[i \notin R_{M^*}(H \cup \{i\})] \geq 1/2$; (II) *If $i \notin R_{M^*}(H \cup \{i\})$, then there exist $|H|$ coefficients $\alpha_1, \alpha_2, \cdots, \alpha_{|H|}$ for which $M^*_i = \sum_{j=1}^{|H|} \alpha_j (M^*_H)_j, \forall j \in [|H|], |\alpha_j| \leq 1$, and $\min_{x\in\mathbb{R}^{|H|}} \|M_H x - M_i\|_g \leq \mathrm{ati}_{g,|H|+1} \cdot \mathrm{mon}_g \cdot \left(\|N_i\|_g + \sum_{j=1}^{|H|} \|(N_H)_j\|_g\right)$.*

Notice that part (II) of the above lemma does not depend on any randomness of H or i. By applying part (I) of the above lemma, it is enough to prove that if we randomly

choose a subset H of $2k$ columns, there is a constant fraction of columns that each column M_i^* can be expressed by a linear combination of columns in M_H^*, and the absolute values of all the fitting coefficients are at most 1. Because of Cramer's rule, it thus suffices to prove the following lemma.

Lemma 20.2.2.

$$\Pr_{H\sim\binom{[m]}{2k}}\left[\left|\left\{ i \;\middle|\; i\in[m]\setminus H, i\notin R_{M^*}(H\cup\{i\})\right\}\right| \geq (m-2k)/4\right] \geq 1/4.$$

20.2.2 Correctness of the Algorithm

We write the input matrix A as $A^* + \Delta$, where $A^* \in \mathbb{R}^{n\times n}$ is the best rank-k approximation to A, and $\Delta \in \mathbb{R}^{n\times n}$ is the residual matrix with respect to A^*. Then $\|\Delta\|_g = \sum_{i=1}^n \|\Delta_i\|_g$ is the optimal cost. As shown in Algorithm 20.1, our approach iteratively eliminates all the columns. In each iteration, we sample a subset of columns, and use these columns to fit other columns. We drop a constant fraction of columns which have a good fitting cost. Suppose the indices of the columns surviving after the i-th outer iteration are $T_i = \{t_{i,1}, t_{i,2}, \cdots, t_{i,m_i}\} \subseteq [n]$. Without loss of generality, we can assume $\|\Delta_{t_{i,1}}\|_g \geq \|\Delta_{t_{i,2}}\|_g \geq \cdots \geq \|\Delta_{t_{i,m_i}}\|_g$. The following claim shows that if we randomly sample $2k$ column indices H from T_i, then the cost of Δ_H will not be large.

Claim 20.2.3. *If $|T_i| = m_i \geq 1000k$,*

$$\Pr_{H\sim\binom{T_i}{2k}}\left[\sum_{j\in H}\|\Delta_j\|_g \leq 400\frac{k}{m_i}\sum_{j=\frac{m_i}{100k}}^{m_i}\|\Delta_{t_{i,j}}\|_g\right] \geq \frac{19}{20}.$$

By an averaging argument, in the following claim, we can show that there is a constant fraction of columns in T_i whose optimal cost is also small.

Claim 20.2.4. *If* $|T_i| = m_i \geq 1000k$,

$$\left| \left\{ t_{i,j} \;\middle|\; t_{i,j} \in T_i, \|\Delta_{t_{i,j}}\|_g \geq \frac{20}{m_i} \sum_{j'=\frac{m_i}{100k}}^{m_i} \|\Delta_{t_{i,j'}}\|_g \right\} \right| \leq \frac{1}{5} m_i.$$

By combining Lemma 20.2.2, part (II) of Lemma 20.2.1 with the above two claims, it is sufficient to prove the following core lemma. It says that if we randomly choose a subset of $2k$ columns from T_i, then we can fit a constant fraction of the columns from T_i with a small cost.

Lemma 20.2.5. *If* $|T_i| = m_i \geq 1000k$,

$$\Pr_{H \sim \binom{T_i}{2k}} \left[\left| \left\{ j \;\middle|\; j \in T_i, \min_{x \in \mathbb{R}^{|H|}} \|A_H x - A_j\|_g \leq C_1 \cdot \frac{1}{m_i} \cdot \sum_{j'=\frac{m_i}{100k}}^{m_i} \|\Delta_{t_{i,j'}}\|_g \right\} \right| \geq \frac{1}{20} m_i \right] \geq \frac{1}{5},$$

where $C_1 = 500 \cdot k \cdot \mathrm{ati}_{g,|S|+1} \cdot \mathrm{mon}_g$.

Let us briefly explain why the above lemma is enough to prove the correctness of our algorithm. For each column $j \in [m]$, either the column j is in T_r and is selected by the end of the algorithm, or $\exists i < r$ such that $j \in T_i \setminus T_{i+1}$. If $j \in T_i \setminus T_{i+1}$, then by the above lemma, we can show that with high probability, $\min_x \|A_{S_{i+1}} x - A_j\|_g \leq O(C_1 \|\Delta\|_1 / |T_i|)$. Thus, $\min_X \|A_{S_{i+1}} X - A_{T_i \setminus T_{i+1}}\|_g \leq O(C_1 \|\Delta\|_1)$. It directly gives a $O(rC_1) = O(C_1 \log n)$ approximation. For the detailed proof of Theorem 20.1.2, we refer the reader to Appendix 20.3.

20.3 Missing Proofs in Section 20.2

20.3.1 Proof of Lemma 20.2.1

Proof. (I) Since $\mathrm{rank}(M^*_{H\cup\{i\}}) \le \mathrm{rank}(M^*) = k$, $|R_{M^*}(H\cup\{i\})| \le k$. Note that H is sampled from $\binom{[m]}{2k}$ uniformly at random, i is sampled from $[m]\backslash H$ uniformly at random, and $|H\cup\{i\}| = 2k+1$. By symmetry we have

$$\Pr_{H\sim\binom{[m]}{2k}, i\sim[m]\backslash H}[i \notin R_{M^*}(H\cup\{i\})] \ge 1 - \frac{k}{2k+1} \ge 1/2.$$

(II) Since $i \notin R_{M^*}(H\cup\{i\})$, by Cramer's rule, there exist $\alpha_1, \alpha_2, \cdots, \alpha_{|H|}$ such that $M^*_i = \sum_{j=1}^{|H|} \alpha_j \cdot (M^*_H)_j$ and $\forall j \in [|H|], |\alpha_j| \le 1$. Then we have

$$\begin{aligned}
\min_{x\in\mathbb{R}^{|H|}} \|M_H x - M_i\|_g \le & \left\| \sum_{j=1}^{|H|} (M_H)_j \alpha_j - M_i \right\|_g \\
= & \left\| \sum_{j=1}^{|H|} (M^*_H)_j \alpha_j - M^*_i + \sum_{j=1}^{|H|} (N_H)_j \alpha_j - N_i \right\|_g \\
= & \left\| \sum_{j=1}^{|H|} (N_H)_j \alpha_j - N_i \right\|_g \\
\le & \ \mathrm{ati}_{g,|H|+1} \cdot \left(\|-N_i\|_g + \sum_{j=1}^{|H|} \|(N_H)_j \alpha_j\|_g \right) \\
\le & \ \mathrm{ati}_{g,|H|+1} \cdot \left(\|-N_i\|_g + \mathrm{mon}_g \cdot \sum_{j=1}^{|H|} \|(N_H)_j\|_g \right) \\
\le & \ \mathrm{ati}_{g,|H|+1} \cdot \left(\mathrm{mon}_g \cdot \|N_i\|_g + \mathrm{mon}_g \cdot \sum_{j=1}^{|H|} \|(N_H)_j\|_g \right) \\
\le & \ \mathrm{ati}_{g,|H|+1} \cdot \mathrm{mon}_g \cdot \left(\|N_i\|_g + \sum_{j=1}^{|H|} \|(N_H)_j\|_g \right),
\end{aligned}$$

where the second step follows from $M = M^* + N$, the third step follows from $\sum_{j=1}^{|H|} (M_H^*)_j \alpha_j - M_i^* = 0$, the fourth step follows from the approximate triangle inequality, the fifth step follows from the fact that $|\alpha_j| \leq 1$ and g is mon_g-monotone, and the sixth step follows from that g is mon_g-monotone.

□

20.3.2 Proof of Lemma 20.2.2

Proof. Using Part (I) of Lemma 20.2.1, we have

$$\Pr_{H \sim \binom{[m]}{2k}, i \sim [m] \setminus H} [i \notin R_{M^*}(H \cup \{i\})] \geq 1/2.$$

For each set H, we define $P_H = \Pr_{i \sim [m] \setminus H}[i \notin R_{M^*}(H \cup \{i\})]$. We have

$$1 \geq \frac{1}{\binom{m}{2k}} \sum_{H \in \binom{[m]}{2k}} P_H \geq 1/2. \tag{20.2}$$

We can show

$$\begin{aligned}
&\frac{1}{\binom{m}{2k}}\left|\left\{H \;\middle|\; H \in \binom{[m]}{2k}, P_H \geq 1/4\right\}\right| \\
&= \frac{1}{\binom{m}{2k}} \sum_{H \in \binom{[m]}{2k}, P_H \geq 1/4} 1 \\
&\geq \frac{1}{\binom{m}{2k}} \sum_{H \in \binom{[m]}{2k}, P_H \geq 1/4} P_H \\
&\geq \frac{1}{2} - \frac{1}{\binom{m}{2k}} \sum_{H \in \binom{[m]}{2k}, P_H < 1/4} P_H \\
&\geq \frac{1}{2} - \frac{1}{\binom{m}{2k}} \sum_{H \in \binom{[m]}{2k}, P_H < 1/4} \frac{1}{4} \\
&\geq \frac{1}{2} - \frac{1}{\binom{m}{2k}} \binom{m}{2k} \frac{1}{4} \\
&= \frac{1}{4},
\end{aligned}$$

where the second step follows since $1 \geq P_H$, the third step follows since Eq. (20.2), the fourth step follows since $P_H < 1/4$.

Thus, we have

$$\left|\left\{H \;\middle|\; H \in \binom{[m]}{2k}, P_H \geq 1/4\right\}\right| \geq \binom{m}{2k}/4.$$

Recall the definition of P_H, we have

$$\left|\left\{H \;\middle|\; H \in \binom{[m]}{2k}, \Pr_{i \sim [m] \setminus H}[i \notin R_{M^*}(H \cup \{i\})] \geq 1/4\right\}\right| \geq \binom{m}{2k}/4,$$

which implies

$$\Pr_{H \sim \binom{[m]}{2k}}\left[\left|\left\{i \;\middle|\; i \in [m] \setminus H, i \notin R_{M^*}(H \cup \{i\})\right\}\right| \geq (m-2k)/4\right] \geq 1/4.$$

□

20.3.3 Proof of Claim 20.2.3

Proof. For simplicity, we omit i in all the subscripts in this proof.

$$
\begin{aligned}
&\Pr_{H\sim\binom{T}{2k}}\left[\sum_{j\in H}\|\Delta_j\|_g \le 400\frac{k}{m}\sum_{j=\frac{m}{100k}}^{m}\|\Delta_{t_j}\|_g\right]\\
=&\Pr_{H\sim\binom{T}{2k}}\left[\sum_{j\in H}\|\Delta_j\|_g \le 400\frac{k}{m}\sum_{j=\frac{m}{100k}}^{m}\|\Delta_{t_j}\|_g \;\middle|\; \exists j\le\frac{m}{100k}, t_j\in H\right]\cdot\Pr_{H\sim\binom{T}{2k}}\left[\exists j\le\frac{m}{100k}, t_j\in H\right]\\
+&\Pr_{H\sim\binom{T}{2k}}\left[\sum_{j\in H}\|\Delta_j\|_g \le 400\frac{k}{m}\sum_{j=\frac{m}{100k}}^{m}\|\Delta_{t_j}\|_g \;\middle|\; \forall j\le\frac{m}{100k}, t_j\notin H\right]\cdot\Pr_{H\sim\binom{T}{2k}}\left[\forall j\le\frac{m}{100k}, t_j\notin H\right]\\
\le&\underbrace{\Pr_{H\sim\binom{T}{2k}}\left[\exists j\le\frac{m}{100k}, t_j\in H\right]}_{C_1}+\underbrace{\Pr_{H\sim\binom{T}{2k}}\left[\sum_{j\in H}\|\Delta_j\|_g \le 400\frac{k}{m}\sum_{j=\frac{m}{100k}}^{m}\|\Delta_{t_j}\|_g \;\middle|\; \forall j\le\frac{m}{100k}, t_j\notin H\right]}_{C_2}
\end{aligned}
$$

It remains to upper bound the terms C_1 and C_2. We can upper bound C_1:

$$
\begin{aligned}
C_1 &= 1-(1-\frac{m/100k}{m})\cdot(1-\frac{m/100k}{m-1})\cdot\dots\cdot(1-\frac{m/100k}{m-2k+1})\\
&\le 1-(1-\frac{m/100k}{m/2})^{2k}\\
&\le 1-(1-\frac{1}{25})\\
&=\frac{1}{25},
\end{aligned}
$$

where the second step follows since $m\ge 1000k$.

Using Markov's inequality,

$$C_2 \le \frac{\mathop{\mathbb{E}}_{H\sim\binom{T}{2k}}\left[\sum_{j\in H}\|\Delta_j\|_g \le 400\frac{k}{m}\sum_{j=\frac{m}{100k}}^{m}\|\Delta_{t_j}\|_g \;\middle|\; \forall j\le\frac{m}{100k}, t_j\notin H\right]}{400\frac{k}{m}\sum_{j=\frac{m}{100k}}^{m}\|\Delta_{t_j}\|_g} \le 1/100,$$

where the second step follows since

$$\begin{aligned}
&\mathop{\mathbb{E}}_{H\sim\binom{T}{2k}}\left[\sum_{j\in H}\|\Delta_j\|_g \le 400\frac{k}{m}\sum_{j=\frac{m}{100k}}^{m}\|\Delta_{t_j}\|_g \;\middle|\; \forall j\le\frac{m}{100k}, t_j\notin H\right]\\
&\le \frac{2k}{m-m/100k}\sum_{j=\frac{m}{100k}}^{m}\|\Delta_{t_j}\|_g\\
&\le 4\frac{k}{m}\sum_{j=\frac{m}{100k}}^{m}\|\Delta_{t_j}\|_g
\end{aligned}$$

□

20.3.4 Proof of Claim 20.2.4

Proof. For simplicity, we omit i in all the subscripts in this proof.

$$\begin{aligned}
&\left|\left\{t_j \;\middle|\; t_j\in T, \|\Delta_{t_j}\|_g \ge \frac{20}{m}\sum_{j'=\frac{m}{100k}}^{m}\|\Delta_{t_{j'}}\|_g\right\}\right|\\
\le\ &\left|\left\{t_j \;\middle|\; t_j\in T, j\le\frac{m}{100k}\right\}\right| + \left|\left\{t_j \;\middle|\; t_j\in T, j>\frac{m}{100k}, \|\Delta_{t_j}\|_g \ge \frac{20}{m}\sum_{j'=\frac{m}{100k}}^{m}\|\Delta_{t_{j'}}\|_g\right\}\right|\\
\le\ &\left|\left\{t_j \;\middle|\; t_j\in T, j\le\frac{m}{100k}\right\}\right| + \left|\left\{t_j \;\middle|\; t_j\in T, j>\frac{m}{100k}, \|\Delta_{t_j}\|_g \ge \frac{10}{m-\frac{m}{100k}}\sum_{j'=\frac{m}{100k}}^{m}\|\Delta_{t_{j'}}\|_g\right\}\right|\\
\le\ &\frac{m}{100k}+\frac{1}{10}(m-\frac{m}{100k})\\
\le\ &\frac{1}{5}m,
\end{aligned}$$

where the second step follows since $\frac{20}{m} \geq \frac{10}{m-m/100k}$ $\square$

20.3.5 Proof of Lemma 20.2.5

Proof. For simplicity, we omit i in all the subscirptis in this proof.

Let $M = A_T$, $M^* = A_T^*$ and $N = \Delta_T$. Then we can apply Lemma 20.2.2 and part (II) of Lemma 20.2.1:

$$\Pr_{H\sim\binom{T}{2k}}\left[\left|\left\{j \in T \;\middle|\; \min_{x\in\mathbb{R}^{|H|}} \|A_H x - A_j\|_g \leq \mathrm{ati}_{g,|H|+1}\cdot \mathrm{mon}_g \cdot \left(\|\Delta_j\|_g + \sum_{j'=1}^{|H|}\|(\Delta_H)_{j'}\|_g\right)\right\}\right| \geq \frac{m}{4}\right] \geq \frac{1}{4} \tag{20.3}$$

By Claim 20.2.3, we have

$$\Pr_{H\sim\binom{T}{2k}}\left[\sum_{j=1}^{|H|}\|(\Delta_H)_j\|_g \leq 400\frac{k}{m}\sum_{j=\frac{m}{100k}}^{m}\|\Delta_{t_j}\|_g\right] \geq \frac{19}{20} \tag{20.4}$$

Due to Claim 20.2.4,

$$\left|\left\{t_j \;\middle|\; t_j \in T, \|\Delta_{t_j}\|_g \geq \frac{20}{m}\sum_{j'=\frac{m}{100k}}^{m}\|\Delta_{t_{j'}}\|_g\right\}\right| \leq \frac{1}{5}m$$

Combining the above equation with the pigeonhole principle, for any $I \subseteq T$ with $|I| \geq m/4$, we have

$$\left|\left\{t_j \;\middle|\; t_j \in I, \|\Delta_{t_j}\|_g < \frac{20}{m}\sum_{j'=\frac{m}{100k}}^{m}\|\Delta_{t_{j'}}\|_g\right\}\right| \geq \frac{1}{4}m - \frac{1}{5}m = \frac{1}{20}m \tag{20.5}$$

Consider the quantity $\|\Delta_j\|_g + \sum_{j=1}^{|H|}\|(\Delta_H)_{j'}\|_g$ in Eq. (20.3). We use Eq. (20.4) and Eq. (20.5) to provide an upper bound,

$$\|\Delta_j\|_g + \sum_{j'=1}^{|H|}\|(\Delta_H)_{j'}\|_g \leq \left(\frac{20}{m} + \frac{400k}{m}\right)\sum_{j'=\frac{m}{100k}}^{m}\|\Delta_{t_{j'}}\|_g.$$

Eq. (20.4) will decrease the final probability by $(1 - 19/20)$ (from $1/4$ to $1/4 - 1/20$). Eq. (20.5) will decrease the size of this set of j by $\frac{1}{5}m$ (from $\frac{1}{4}m$ to $\frac{1}{4}m - \frac{1}{5}m$).

Putting it all together, we can update Eq. (20.3) in the following sense,

$$\Pr_{H\sim\binom{T}{2k}}\left[\left|\left\{ j \;\middle|\; j \in T, \min_{x\in\mathbb{R}^{|H|}} \|A_H x - A_j\|_g \leq C \cdot \frac{1}{m} \cdot \sum_{j'=\frac{m}{100k}}^{m} \|\Delta_{t_{j'}}\|_g \right\}\right| \geq (\frac{1}{4} - \frac{1}{5})m\right] \geq \frac{1}{4} - \frac{1}{20}.$$

where

$$C = (400 + 20) \cdot k \cdot \mathrm{ati}_{g,|H|+1} \cdot \mathrm{mon}_g \,.$$

□

20.3.6 Proof of Theorem 20.1.2

Proof. The running time is discussed at the beginning of Section 20.2. In the remaining of the proof, we will focus on the correctness of Algorithm 20.1.

Firstly, let us consider the size of the output S. For $i \in \{0\} \cup [r]$, let $m_i = |T_i|$. We set number of rounds r to be the smallest value such that $m_r < 1000k$. By the algorithm, we have $m_i = m_{i-1} - 2k - (m_{i-1} - 2k)/20 \leq 19/20 \cdot m_{i-1}$. Thus, $r = O(\log n)$. In each round i, the size of S_i is $2k$. Then $|S| = |T_r| + \sum_{i=1}^{r} |S_i| \leq 1000k + r \cdot 2k \leq O(k \log n)$.

Next, let us consider the quality of S. Since each regression call has $1 - 1/\operatorname{poly}(n)$ success probability, all the regression calls succeed with probability at least $1 - 1/\operatorname{poly}(n)$. In the remaining of the proof, we condition on that all the regression calls succeed.

Let us fix $i \in [r], j \in [\log n]$. Recall that $T_i = \{t_{i,1}, t_{i,2}, \cdots, t_{i,m_i}\}$ and $\|\Delta_{t_{i,1}}\|_g \geq \|\Delta_{t_{i,2}}\|_g \geq \cdots \geq \|\Delta_{t_{i,m_i}}\|_g$. By regression property and Lemma 20.2.5, with probability at

least $1/4$,

$$\begin{aligned}
&\sum_{q\in R_i^{(j)}} \min_{x\in\mathbb{R}^{2k}} \|A_{S_i^{(j)}}x - A_q\|_g \\
\leq\ &\sum_{q\in R_i^{(j)}} v_{i,q}^{(j)} \\
\leq\ &\mathrm{reg}_{g,2k}\cdot(m_i-2k)\cdot 500\cdot k\cdot \mathrm{ati}_{g,2k+1}\cdot \mathrm{mon}_g\, /m_i \cdot \sum_{j'=\frac{m_i}{100k}}^{m_i} \|\Delta_{t_{i,j'}}\|_g \\
\leq\ &\mathrm{reg}_{g,2k+1}\cdot \mathrm{ati}_{g,2k+1}\cdot \mathrm{mon}_g \cdot O(k)\cdot \sum_{j'=\frac{m_i}{100k}}^{m_i} \|\Delta_{t_{i,j'}}\|_g.
\end{aligned}$$

For each $i\in[r]$, since we repeat $\log(n)$ times, the success probability can be boosted to at least $1-1/\operatorname{poly}(r)$, i.e., with probability at least $1-1/\operatorname{poly}(r)$, we have

$$\sum_{q\in R_i} \min_{x\in\mathbb{R}^{2k}} \|A_{S_i}x - A_q\|_g \leq \mathrm{reg}_{g,2k+1}\cdot \mathrm{ati}_{g,2k+1}\cdot \mathrm{mon}_g \cdot O(k)\cdot \sum_{j'=\frac{m_i}{100k}}^{m_i} \|\Delta_{t_{i,j'}}\|_g. \tag{20.6}$$

In the remaining of the proof, we condition on above inequality for every $i\in[r]$. Without

loss of generality, we suppose $\|\Delta_1\|_g \geq \|\Delta_2\|_g \geq \cdots \geq \|\Delta_n\|_g$. We have

$$
\begin{aligned}
& \sum_{q=1}^{n} \min_{x \in \mathbb{R}^{|S|}} \|A_S x - A_q\|_g \\
\leq & \left(\sum_{q \in T_r} \min_{x \in \mathbb{R}^{|T_r|}} \|A_{T_r} x - A_q\|_g \right) + \left(\sum_{i=1}^{r} \sum_{q \in T_{i-1} \setminus T_i} \min_{x \in \mathbb{R}^{2k}} \|A_{S_i} x - A_q\|_g \right) \\
= & \sum_{i=1}^{r} \sum_{q \in T_{i-1} \setminus T_i} \min_{x \in \mathbb{R}^{2k}} \|A_{S_i} x - A_q\|_g \\
\leq & \sum_{i=1}^{r} \mathrm{reg}_{g,2k+1} \cdot \mathrm{ati}_{g,2k+1} \cdot \mathrm{mon}_g \cdot O(k) \cdot \sum_{j'=\frac{m_i}{100k}}^{m_i} \|\Delta_{t_{i,j'}}\|_g \\
\leq & \sum_{i=1}^{r} \mathrm{reg}_{g,2k+1} \cdot \mathrm{ati}_{g,2k+1} \cdot \mathrm{mon}_g \cdot O(k) \cdot \sum_{j'=\frac{m_i}{100k}}^{m_i} \|\Delta_{j'}\|_g \\
= & \mathrm{reg}_{g,2k+1} \cdot \mathrm{ati}_{g,2k+1} \cdot \mathrm{mon}_g \cdot O(k) \cdot \sum_{j'=1}^{n} \|\Delta_{j'}\|_g \left(\operatorname*{argmin}_{i \in [r]} \{m_i < j'\} - \operatorname*{argmin}_{i \in [r]} \left\{ \frac{m_i}{100k} < j' \right\} + O(1) \right) \\
\leq & \mathrm{reg}_{g,2k+1} \cdot \mathrm{ati}_{g,2k+1} \cdot \mathrm{mon}_g \cdot O(k \log k) \cdot \|\Delta\|_g,
\end{aligned}
$$

where the third step follows from $T_{i-1} \setminus T_i = S_i \cup R_i$ and Equation (20.6), the forth step follows from $\|\Delta_{j'}\|_g \geq \|\Delta_{t_{i,j'}}\|_g$, and the last step follows from

$$
\left(\operatorname*{argmin}_{i \in [r]} \{m_i < j'\} - \operatorname*{argmin}_{i \in [r]} \left\{ \frac{m_i}{100k} < j' \right\} + O(1) \right) \leq O(\log k).
$$

□

20.4 Necessity of the Properties of g

We note that an approximate triangle inequality is necessary to obtain a column subset selection algorithm. An example function not satisfying this is the "jumping function": $g_\tau(x) = |x|$ if $|x| \geq \tau$, and $g_\tau(x) = 0$ otherwise. For the identity matrix I and any $k = \Omega(\log n)$, the Johnson-Lindenstrauss lemma implies one can find a rank-k matrix B for which $\|I - B\|_\infty < 1/2$, that is, all entries of $I - B$ are at most $1/2$. If we set $\tau = 1/2$, then $\|I - B\|_{g_\tau} = 0$, but for any subset I_S of columns of the identity matrix we choose, necessarily $\|I - I_S X\|_\infty \geq 1$, so $\|I - B\|_{g_\tau} > 0$. Consequently, there is no subset of a small number of columns which obtains a $\mathrm{poly}(k \log n)$-approximation with the jumping function loss measure.

While the jumping function does not satisfy the Approximate triangle inequality, it does satisfy our only other required structural property, the Monotone property.

There are interesting examples of functions g which are only approximately monotone in the above sense, such as the quantile function $\rho_\tau(x)$, studied in [YMM14] in the context of regression, where for a given parameter τ, $\rho_\tau(x) = \tau x$ if $x \geq 0$, and $\rho_\tau(x) = (\tau - 1)x$ if $x < 0$. Only when $\tau = 1/2$ is this a monotone function with $\mathrm{mon}_g = 1$ in the above definition, in which case it coincides with the absolute value function up to a factor of $1/2$. For other constant $\tau \in (0, 1)$, mon_g is a constant. The loss function $\rho_\tau(x)$ is also sometimes called the scalene loss, and studied in the context of low rank approximation in [UHZ+16].

When $\tau = 1$ this is the so-called Rectified Linear Unit (ReLU) function in machine learning, i.e., $\rho_1(x) = x$ if $x \geq 0$ and $\rho_1(x) = 0$ if $x < 0$. In this case $\mathrm{mon}_g = \infty$. and the optimal rank-k approximation for any matrix A is 0, since $\|A - \lambda \mathbf{1}\mathbf{1}^\top\|_{\rho_1} = 0$ if one sets λ to

be a large enough positive number, thereby making all entries of $A - \lambda \mathbf{1}\mathbf{1}^\top$ negative and their corresponding cost equal to 0. Notice though, that there are no good column subset selection algorithms for some matrices A, such as the $n \times n$ identity matrix. Indeed, for the identity, if we choose any subset A_S of at most $n-1$ columns of A, then for any matrix X there will be an entry of $A - A_S X$ which is positive, causing the cost to be positive. Since we will restrict ourselves to column subset selection, being approximately monotone with a small value of mon_g in the above definition is in fact necessary to obtain a good approximation with a small number of columns, as the ReLU function illustrates (see also related functions such as the leaky ReLU and squared ReLU [ZSJ+17, BHL18, GKM18]).

Note that the ReLU function is an example which satisfies the triangle inequality, showing that our additional assumption of approximate monotonicity is required.

Thus, if either property fails to hold, there need not be a small subset of columns spanning a relative error approximation. These examples are stated in more detail below.

20.4.1 Functions without Approximate Triangle Inequality

In this section, we show how to construct a function f such that it is not possible to obtain a good entrywise-f low rank approximation by selecting a small subset of columns. Furthermore, f is monotone but does not have the approximate triangle inequality. Theorem 20.4.3 shows this result.

First, we show that a small subset of columns cannot give a good low rank approximation in ℓ_∞ norm. Then we reduce the ℓ_∞ column subset selection problem to the entrywise-f column subset selection problem.

The following is the Johnson-Lindenstrauss lemma.

Lemma 20.4.1 (JL Lemma)**.** *For any $n \geq 1, \epsilon \in (1/\sqrt{n}, 1/2)$, there exists $U \in \mathbb{R}^{n \times k}$ with $k = O(\epsilon^{-2} \log(n))$ such that $\|UU^\top - I_n\|_\infty \leq O(\epsilon)$, where $I_n \in \mathbb{R}^{n \times n}$ is an identity matrix.*

Theorem 20.4.2. *For $n \geq 1$, there is a matrix $A \in \mathbb{R}^{n \times n}$ with the following properties. Let $k = \Theta(\epsilon^{-2} \log(n))$ for an arbitrary $\epsilon \in (1/\sqrt{n}, 1/2)$. Let $D \in \mathbb{R}^{n \times n}$ denote a diagonal matrix with $n - 1$ nonzeros on the diagonal. We have*

$$\min_{X \in \mathbb{R}^{n \times n}} \|XDA - A\|_\infty \geq 1$$

and

$$\min_{\text{rank}-k \ A'} \|A' - A\|_\infty < O(\epsilon).$$

Proof. We choose A to be the identity matrix. By Lemma 20.4.1, we can find a rank-k matrix B for which

$$\|A - B\|_\infty \leq O(\epsilon).$$

Since A is an $n \times n$ identity matrix, even if we can use $n - 1$ columns to fit the other columns, the cost is still at least 1. □

In the following, we state the construction of our function f.

Definition 20.4.1. We define function $f(x)$ to be $f(x) = c$ if $|x| > \tau$ and $f(x) = 0$ if $|x| \leq \tau$. Given matrix A, we define $\|A\|_f = \sum_{i=1}^n \sum_{j=1}^n f(A_{i,j})$.

Theorem 20.4.3 (No good subset of columns)**.** *For any $n \geq 1$, there is a matrix $A \in \mathbb{R}^{n \times n}$ with the following property. Let $k \geq c \log n$ for a sufficiently large constant $c > 0$. Let*

$D \in \mathbb{R}^{n \times n}$ denote an arbitrary diagonal matrix with $n-1$ nonzeros on the diagonal. For f with parameter $\tau = 1/4$, we have

$$\min_{X \in \mathbb{R}^{n \times n}} \|XDA - A\|_f > 0$$

and

$$\min_{\text{rank}-k \ A'} \|A' - A\|_f = 0.$$

Proof. We can set A to be the identity matrix. Due to Theorem 20.4.2, there exists A' for which $\min_{\text{rank}-k \ A'} \|A' - A\|_\infty < 1/4$, which implies that $\min_{\text{rank}-k \ A'} \|A' - A\|_f = 0$. Also due to Theorem 20.4.2, we have $\min_{X \in \mathbb{R}^{n \times n}} \|XDA - A\|_\infty = 1$, and thus, $\min_{X \in \mathbb{R}^{n \times n}} \|XDA - A\|_f > 0$.

□

20.4.2 ReLU Function Low Rank Approximation

In this section, we discuss a function which has the approximate triangle inequality but is not symmetric. The specific function we discuss in this section is ReLU . The definition of ReLU is defined in Definition 20.4.2. First, we show that ReLU low rank approximation has a trivial best rank-k approximation. Second, we show that for some matrices, there is no small subset of columns which can give a good low rank approximation.

Definition 20.4.2. We define function $\text{ReLU}(x)$ to be $\text{ReLU}(x) = \max(0, x)$. Given matrix A, we define $\|A\|_{\text{ReLU}} = \sum_{i=1}^{n} \sum_{j=1}^{n} \text{ReLU}(A_{i,j})$.

In the rank-k approximation problem, given an input matrix A, the goal is to find a rank-k matrix B for which $\|A - B\|_{\text{ReLU}}$ is minimized. A simple observation is that if we set

B to be a matrix with each entry of value $\|A\|_\infty$, then the value of each entry of $A - B$ is at most 0. Thus, $\|A - B\|_{\mathrm{ReLU}} = 0$. Furthermore, the rank of B is 1.

Now, consider the column subset selection problem, let input matrix $A \in \mathbb{R}^{n \times n}$ be an identity matrix. Then even if we can choose $n - 1$ columns, they can never fit the remaining column. Thus, the cost is at least 1. But as discussed, the best rank-k cost is always 0. This implies that any subset of columns cannot give a good rank-k approximation.

20.5 Regression Solvers

In this section, we discuss several regression solvers.

20.5.1 Regression for Convex g

Notice that when the function g is convex, the regression problem $\min_{X\in\mathbb{R}^{d\times m}} \|AX - B\|_g$ for any given matrices $A \in \mathbb{R}^{n\times d}, B \in \mathbb{R}^{n\times m}$ is a convex optimization problem. Thus, it can be solved exactly by convex optimization algorithms.

Fact 20.5.1. *Let g be a convex function. Given $A \in \mathbb{R}^{n\times d}, B \in \mathbb{R}^{n\times m}$, the regression problem $\min_{X\in\mathbb{R}^{d\times m}} \|AX - B\|_g$ can be solved exactly by convex optimization in $\mathrm{poly}(n, d, m)$ time.*

If a function g has additional properties, i.e. g is symmetric, monotone and grows subquadratically, then there is a better running time constant approximation algorithm shown in [CW15b]. Here "grows quadratically" means that there is an $\alpha \in [1, 2]$ and $c_g > 0$ so that for a, a' with $|a| > |a'| > 0$,

$$\left|\frac{a}{a'}\right|^\alpha \geq \frac{g(a)}{g(a')} \geq c_g \left|\frac{a}{a'}\right|.$$

This kind of function g is also called a "sketchable" function. Notice that the Huber function satisfies the above properties.

Theorem 20.5.2 (Modified version of Theorem 3.1 of [CW15b])**.** *Function g is symmetric, monotone and grows subquadratically (g is a G-function defined by [CW15b]). Given a matrix $A \in \mathbb{R}^{n\times d}$ and a matrix $B \in \mathbb{R}^{n\times m}$, there is an algorithm which can output a matrix $\widehat{X} \in \mathbb{R}^{d\times m}$ and a fitting cost vector $y \in \mathbb{R}^m$ such that with probability at least $1-1/\mathrm{poly}(nm)$, $\forall i \in [m], \|A\widehat{X}_i - B_i\|_g \leq O(1)\cdot \min_{x\in\mathbb{R}^d} \|Ax - B_i\|_g$, and $y_i = \Theta(\|A\widehat{X}_i - B_i\|_g)$. Furthermore, the running time is at most $\widetilde{O}(\mathrm{nnz}(A) + \mathrm{nnz}(B) + m \cdot \mathrm{poly}(d \log n))$.*

Proof. We run $O(\log(nm))$ repetitions of the single column regression algorithm shown in Theorem 3.1 of [CW15b] for all columns B_i for $i \in [m]$. For each regression problem $\|Ax - B_i\|_g$, we take the solution whose estimated cost is the median among these $O(\log(nm)$ repetitions as $\widehat{X}_i$. Then by the Chernoff bound, we can boost the success probability of each column to $1 - 1/\operatorname{poly}(nm)$. By taking a union bound over all columns, we complete the proof. □

20.5.2 ℓ_p Regression

One of the most important cases in regression and low rank approximation problems is when the error measure is ℓ_p. For ℓ_p regression, though it can be solved by convex optimization/linear programming exactly, we can get a much faster running time if we allow some approximation ratios. In the following theorem, we show that there is an algorithm which can be used to solve ℓ_p regression for any $p \geq 1$.

Theorem 20.5.3 (Modified version of [WZ13])**.** *Let $p \geq 1, \epsilon \in (0, 1)$. Given a matrix $A \in \mathbb{R}^{n \times d}$ and a matrix $B \in \mathbb{R}^{n \times m}$, there is an algorithm which can output a matrix $\widehat{X} \in \mathbb{R}^{d \times m}$ and a fitting cost vector $y \in \mathbb{R}^m$ such that with probability at least $1 - 1/\operatorname{poly}(nm)$, $\forall i \in [m], \|A\widehat{X}_i - B_i\|_p^p \leq (1+\epsilon) \cdot \min_{x \in \mathbb{R}^d} \|Ax - B_i\|_p^p$, and $y_i = \Theta(\|A\widehat{X}_i - B_i\|_p^p)$. Furthermore, the running time is at most $\widetilde{O}(\operatorname{nnz}(A) + \operatorname{nnz}(B) + mn^{\max(1-2/p,0)} \cdot \operatorname{poly}(d))$.*

Proof. As in the proof of Theorem 20.5.2, we only need to run $O(\log(nm))$ repetitions of the single column regression algorithm shown in [WZ13]. □

20.5.3 ℓ_0 Regression

Definition 20.5.1 (Regular partition)**.** Given a matrix $A \in \mathbb{R}^{n\times k}$, we say $\{S_1, S_2, \cdots, S_h\}$ is a regular partition for $[n]$ with respect to the matrix A if, for each $i \in [h]$,

$$\mathrm{rank}(A^{S_i}) = |S_i|, \text{ and } \mathrm{rowspan}(A^{S_i}) = \mathrm{rowspan}\left(A^{\cup_{j=i}^{h} S_j}\right),$$

where $A^{S_i} \in \mathbb{R}^{|S_i|\times k}$ denotes the matrix that selects a subset S_i of rows of the matrix A.

Algorithm 20.2 ℓ_0 regression [APY09]

  end for
  return x'
end procedure

[APY09] studied the Nearest Codeword problem over finite fields $\mathbb{F}_2$. Their proof can be extended to the real field and generalized to Theorem 20.5.4. For completeness, we still provide the proof of the following result.

Theorem 20.5.4 (Generalization of [APY09])**.** *Given matrix $A \in \mathbb{R}^{n\times k}$ and vector $\mathbb{R}^n$, for any $c \in [1, k]$, there is an algorithm (Algorithm 20.2) that runs in $n^{O(1)}$ time and outputs a vector $x' \in \mathbb{R}^k$ such that*

$$\|Ax' - b\|_0 \leq k \min_{x\in\mathbb{R}^k} \|Ax - b\|_0.$$

Proof. Let $x^* \in \mathbb{R}^k$ denote the optimal solution to $\min_{x\in\mathbb{R}^k} \|Ax - b\|_0$. We define set E as follows

$$E = \{i \in [n] \mid (Ax^*)_i \neq b_i\}.$$

We create a regular partition $\{S_1, S_2, \cdots, S_h\}$ for $[n]$ with respect to A.

Let i denote the smallest index such that $|S_i \cap E| = 0$, i.e.,

$$i = \min\{j \mid |S_j \cap E| = 0\}.$$

The linear equation we want to solve is $A^{S_i}x = b_{S_i}$. Let $\widetilde{x} \in \mathbb{R}^k$ denote a solution to $A^{S_i}\widetilde{x} = A^{S_i}x^*$ (Note that, by our choice of i, $b_{S_i} = A^{S_i}x^*$). Then we can rewrite $\|A\widetilde{x} - b\|_0$ in the following sense,

$$\|A\widetilde{x} - b\|_0 = \sum_{j=1}^{i-1} \left\|A^{S_j}\widetilde{x} - b_{S_j}\right\|_0 + \sum_{j=i}^{h} \left\|A^{S_j}\widetilde{x} - b_{S_j}\right\|_0. \tag{20.7}$$

For each $j \in \{1, 2, \cdots, i-1\}$, we have

$$\begin{aligned} \|A^{S_j}\widetilde{x} - b_{S_j}\|_0 &\leq k \\ &\leq \|A^{S_j}x^* - b_{S_j}\|_0 \cdot \lceil k \rceil, \end{aligned} \tag{20.8}$$

where the first step follows from $|S_0| \leq k$, and the last step follows from $\|A^{S_j}x^* - b_{S_j}\|_0 \geq 1$, $\forall j \in [i-1]$.

Note that, by our choice of i, we have $A^{S_i}\widetilde{x} = A^{S_i}x^*$. Then for each $j \in \{i, i+1, \cdots, n\}$, using the regular partition property, there always exists a matrix $P_{(j)}$ such that $A^{S_j} = P_{(j)}A^{S_i}$. Then we have

$$A^{S_j}\widetilde{x} = P_{(j)}A^{S_i}\widetilde{x} = P_{(j)}A^{S_i}x^* = A^{S_j}x^*. \tag{20.9}$$

Plugging Eq. (20.8) and (20.9) into Eq. (20.7), we have

$$\begin{aligned}
\|A\widetilde{x} - b\|_0 &= \sum_{j=1}^{i-1} \left\|A^{S_j}\widetilde{x} - b_{S_j}\right\|_0 + \sum_{j=i}^{h} \left\|A^{S_j}\widetilde{x} - b_{S_j}\right\|_0 \\
&\leq k \sum_{j=1}^{i-1} \left\|A^{S_j}x^* - b_{S_j}\right\|_0 + \sum_{j=i}^{h} \left\|A^{S_j}x^* - b_{S_j}\right\|_0 \\
&\leq k\|Ax^* - b\|_0.
\end{aligned}$$

This completes the proof. □

20.6 Hardness

20.6.1 Column Subset Selection for the Huber Function

The rough idea here is to define $k = \Omega(\sqrt{\log n})$ groups of columns, where we carefully choose the i-th group to have $n^{1-2i\epsilon}$ columns, $\epsilon = .2/(1.5k)$, and in the i-th group each column has the form

$$n^{1.5i\epsilon} \cdot 1^n + [\pm n^{-.2+i\epsilon}, \ldots, \pm n^{-.2+i\epsilon}, \pm n^{.5+2i\epsilon}, \ldots, \pm n^{.5+2i\epsilon}],$$

where there are $n - n^{.1}$ coordinates where the perturbation is randomly either $+n^{-.2+i\epsilon}$ or $-n^{-.2+i\epsilon}$, and the remaining $n^{.1}$ coordinates are randomly either $+n^{.5+2i\epsilon}$ or $-n^{.5+2i\epsilon}$. We call the former type of coordinates "small noise", and the latter "large noise". All remaining columns in the matrix are set to 0. Because of the random signs, it is very hard to fit the noise in one column to that of another column. One can show, that to approximate a column in the j-th group by a column in the i-th group, $i < j$, one needs to scale by roughly $n^{1.5(j-i)\epsilon}$, just to cancel out the "mean" $n^{1.5j\epsilon} \cdot 1^n$. But when doing so, since the Huber function is quadratic for small values, the scaled small noise is now magnified more than linearly compared to what it was before, and this causes a column in the i-th group not to be a good approximation of a column in the j-th group. On the other hand, if you want to approximate a column in the j-th group by a column in the i-th group, $i > j$, one again needs to scale by roughly $n^{1.5(j-i)\epsilon}$ just to cancel out the "mean", but now one can show the large noise from the column in the i-th group is too large and remains in the linear regime, causing a poor approximation. The details of this construction are given in the following theorem.

Theorem 20.6.1. *Let $H(x)$ denote the modified Huber function with $\tau = 1$, i.e.,*

$$H(x) = \begin{cases} x^2/\tau, & \text{if } |x| < \tau; \\ |x|, & \text{if } |x| \geq \tau. \end{cases}$$

For any $n \geq 1$, there is a matrix $A \in \mathbb{R}^{n \times n}$ such that, if we select $o(\sqrt{\log n})$ columns to fit the entire matrix, there is no $O(1)$-approximation, i.e., for any subset $S \subseteq [n]$ with $|S| = o(\sqrt{\log n})$,

$$\min_{X \in \mathbb{R}^{|S| \times n}} \|A_S X - A\|_H \geq \omega(1) \cdot \min_{\text{rank}-1 \ A'} \|A' - A\|_H.$$

Proof. Suppose there is an algorithm which only finds a subset with size $k/2 = o(\sqrt{\log n})$. We want to prove a lower bound on its approximation ratio.

Let $\epsilon = 0.2/(1.5k)$. Let A denote a matrix with $k+1$ groups of columns.

For each group $i \in [k]$, I_i has $n^{1-2i\epsilon}$ columns which are

$$\begin{bmatrix} n^{1.5i\epsilon} \\ n^{1.5i\epsilon} \\ n^{1.5i\epsilon} \\ \vdots \\ n^{1.5i\epsilon} \\ n^{1.5i\epsilon} \\ n^{1.5i\epsilon} \\ n^{1.5i\epsilon} \end{bmatrix} + \begin{bmatrix} \pm n^{-0.2+i\epsilon} \\ \pm n^{-0.2+i\epsilon} \\ \vdots \\ \pm n^{-0.2+i\epsilon} \\ \pm n^{0.5+2i\epsilon} \\ \pm n^{0.5+2i\epsilon} \\ \vdots \\ \pm n^{0.5+2i\epsilon} \end{bmatrix} \in \mathbb{R}^n,$$

where $\pm$ indicates i.i.d. random signs. For the error column, the first $n - n^{0.1}$ rows are $n^{-0.2+i\epsilon}$, and the last $n^{0.1}$ rows are $n^{0.5+2i\epsilon}$.

The last group of $n - \sum_{i=1}^{k} n^{1-2i\epsilon}$ columns are

$$\begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ 0 \end{bmatrix} \in \mathbb{R}^n.$$

The optimal cost is at most

$$\begin{aligned} \sum_{i=1}^{k} n^{1-2i\epsilon} \cdot ((n - n^{0.1})H(n^{-0.2+i\epsilon}) + n^{0.1}H(n^{0.5+2i\epsilon})) &\leq \sum_{i=1}^{k} n^{1-2i\epsilon}(n \cdot n^{-0.4+2i\epsilon} + n^{0.6+2i\epsilon}) \\ &\leq O(kn^{1.6}), \end{aligned}$$

where the second step follows since $n^{-0.2+i\epsilon} < 1$ and $n^{0.5+2i\epsilon} \geq 1$. Thus, it implies

$$\min_{\text{rank}-1\ A'} \|A' - A\|_H \leq O(kn^{1.6}).$$

Now let us consider the lower bound for using a subset of columns to fit the matrix. First, we fix a set $S = \{j_1, j_2, \cdots, j_{k/2}\}$ of $k/2$ columns. Since there are k groups, and $|S| \leq k/2$, the number of groups I_i for $i \in [k]$ with $S \cap I_i = \emptyset$ is at least $k/2$. It means that there are at least $k/2$ groups for which S does not have any column from them. Notice that the optimal cost is at most $O(kn^{1.6})$, so it suffices to prove that $\forall i \in [k]$ with $I_i \cap S = \emptyset$, each column $j \in I_i$ will contribute a cost of $\omega(n^{0.6+2i\epsilon})$.

For notation, we use group(j) to denote the index of the group which contains the column j. For each column j, we use Δ_j to denote the noise part, and use A_j^* to denote the rank-1 "ground truth" part. Notice that $A_j = A_j^* + \Delta_j$.

Claim 20.6.2 (Noise cannot be used to fit other vectors)**.** *Let $x_1, x_2, \cdots, x_s \in \mathbb{R}^m$ be s random sign vectors. Then with probability at least $1 - 2^s \cdot 2^{-\Theta(m/2^s)}$, $\forall \alpha_1, \alpha_2, \cdots, \alpha_s \in \mathbb{R}$,*

the size of $Z_{\alpha_1,\alpha_2,\cdots,\alpha_s} = \{i \in [m] \mid \mathrm{sign}((\alpha_1 x_1)_i) = \mathrm{sign}((\alpha_2 x_2)_i) = \cdots = \mathrm{sign}((\alpha_s x_s)_i) = \mathrm{sign}(+1)\}$ *is at least* $\Omega(m/2^s)$.

Proof. For a set of fixed $\alpha_1, \alpha_2, \cdots, \alpha_s$, the claim follows from the Chernoff bound. Since there are 2^s different possibilities of signs of $\alpha_1, \cdots, \alpha_s$, taking a union bound over them completes the proof. □

Now we consider a specific column $j \in I_i$ for some $i \in [k]$, where $I_i \cap S = \emptyset$. Suppose the fitting coefficients are $\alpha_1, \alpha_2, \cdots, \alpha_{k/2}$. Consider the following term

$$\begin{aligned}&(\alpha_1 A_{j_1} + \alpha_2 A_{j_2} + \cdots + \alpha_{k/2} A_{k/2}) - A_j \\ =\ &(\alpha_1 A^*_{j_1} + \alpha_2 A^*_{j_2} + \cdots + \alpha_{k/2} A^*_{k/2} - A^*_j) + (\alpha_1 \Delta_{j_1} + \alpha_2 \Delta_{j_2} + \cdots + \alpha_{k/2} \Delta_{k/2} - \Delta_j)\end{aligned}$$

Let $u^* = (\alpha_1 A^*_{j_1} + \alpha_2 A^*_{j_2} + \cdots + \alpha_{k/2} A^*_{k/2} - A^*_j)$. By Claim 20.6.2, with probability at least $1 - (k/2) \cdot 2^{-\Theta(n/2^{k/2})}$,

$$|\{t \in [n] \mid \mathrm{sign}(u^*_t) = \mathrm{sign}(\alpha_1 \Delta_{j_1,t}) = \cdots = \mathrm{sign}(\alpha_{k/2} \Delta_{j_{k/2},t}) = \mathrm{sign}(-\Delta_{j,t})\}| = \Omega(n/2^{k/2}).$$

Observe that all the coordinates of u^* are the same, and the absolute value of each entry of u^* should be at most $O(n^{1.5i\epsilon})$. Otherwise the column already has $\omega(n/2^{k/2} \cdot n^{1.5i\epsilon}) = \omega(n^{0.6+2i\epsilon})$ cost. Thus, the magnitude of each entry of $\alpha_1 A^*_{j_1} + \alpha_2 A^*_{j_2} + \cdots + \alpha_{k/2} A^*_{k/2}$ is $\Theta(n^{1.5i\epsilon})$. Thus, there exists $t \in [k/2]$, such that the absolute value of each entry of $\alpha_t A^*_{j_t}$ is at least $\Omega(n^{1.5i\epsilon}/k)$. Then there are two cases.

The first case is $\mathrm{group}(t) < \mathrm{group}(j)$. Let $\mathrm{group}(t) = i'$. Then $|\alpha_t| = \Omega(n^{1.5(i-i')\epsilon}/k)$. By Claim 20.6.2 again, with probability at least $1 - (k/2) \cdot 2^{-\Theta(n/2^{k/2})}$, the size of

$$\{z \in [n - n^{0.1}] \mid \mathrm{sign}(u^*_z) = \mathrm{sign}(\alpha_1 \Delta_{j_1,z}) = \cdots = \mathrm{sign}(\alpha_{k/2} \Delta_{j_{k/2},z}) = \mathrm{sign}(-\Delta_{j,z})\}$$

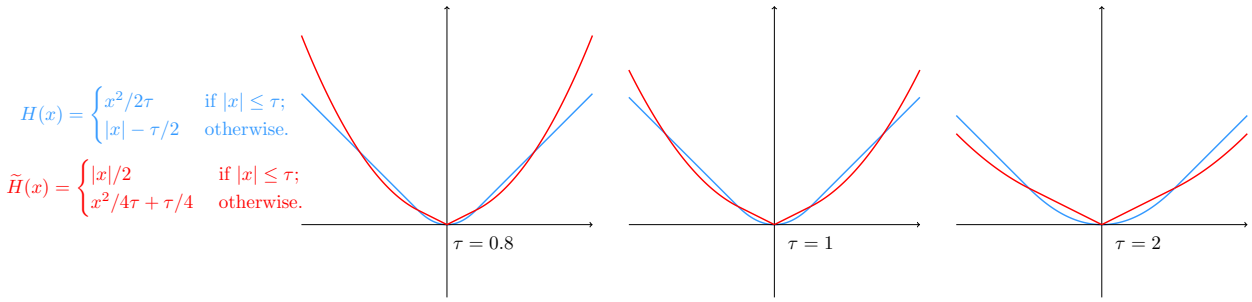

Figure 20.1: The blue curve is the Huber function which combines an ℓ_2-like measure for small x with an ℓ_1-like measure for large x. The red curve is the "reverse" Huber function which combines an ℓ_1-like measure for small x with an ℓ_2-like measure for large x.

is at least $\Omega(n/2^{k/2})$. Thus, the cost to fit is at least $\Omega(n/2^{k/2}) \cdot (n^{-0.2+i'\epsilon} n^{1.5(i-i')\epsilon}/k)^2 = \omega(n^{0.6+2i\epsilon})$.

The second case is $\text{group}(t) > \text{group}(j)$. Let $\text{group}(t) = i'$. Then $|\alpha_t| = \Omega(n^{1.5(i-i')\epsilon}/k)$. By Claim 20.6.2 again, with probability at least $1 - (k/2) \cdot 2^{-\Theta(n^{0.1}/2^{k/2})}$, the size of

$$\{z \in \{n - n^{0.1} + 1, \cdots, n\} \mid \text{sign}(u_z^*) = \text{sign}(\alpha_1 \Delta_{j_1,z}) = \cdots = \text{sign}(\alpha_{k/2} \Delta_{j_{k/2},z}) = \text{sign}(-\Delta_{j,z})\}$$

is at least $\Omega(n^{0.1}/2^{k/2})$. Thus, the fitting cost is at least $\Omega(n^{0.1}/2^{k/2}) \cdot (n^{0.5+2i'\epsilon} n^{1.5(i-i')\epsilon}/k) = \omega(n^{0.6+2i\epsilon})$.

By taking a union bound over all columns j, we have with probability at least $1 - 2^{n^{\Theta(1)}}$, the total cost to fit by a column subset S is at least $\omega(kn^{1.6})$.

Then, by taking a union bound over all the $\binom{n}{k}$ number of sets S, we complete the proof. □

20.6.2 Column Subset Selection for the Reverse Huber Function

In this section, we consider a "reverse Huber function": $g(x) = x^2$ if $x \geq 1$ and $g(x) = |x|$ for $x \leq 1$.

Theorem 20.6.3. *Let $g(x)$ denote the "reverse Huber function" with $\tau = 1$, i.e.,*

$$H(x) = \begin{cases} x^2/\tau, & \text{if } |x| > \tau; \\ |x|, & \text{if } |x| \leq \tau. \end{cases}$$

For any $n \geq 1$, there is a matrix $A \in \mathbb{R}^{n \times n}$ such that, if we select only 1 column to fit the entire matrix, there is no $n^{o(1)}$-approximation to the best rank-1 approximation, i.e., for any subset $S \subseteq [n]$ with $|S| = 1$,

$$\min_{X \in \mathbb{R}^{|S| \times n}} \|A_S X - A\|_g \geq n^{\Omega(1)} \cdot \min_{\text{rank}-1 \ A'} \|A' - A\|_g.$$

Proof. Let $A \in \mathbb{R}^{n \times n}$ have one column that is $a = (n^{1/2}, 0, \ldots, 0)^\top$ and $n-1$ columns that are each equal to $b = (0, 1/n, 1/n, \ldots, 1/n)^\top$. If we choose one column which has the form as a to fit the other columns, the cost is at least $(n-1)^2/n = \Theta(n)$. If we choose one column which has the form as b to fit the other columns, the cost is at least $(n^{1/2})^2 = \Theta(n)$.

Now we consider using a vector $c = (1/n^{1/4}, 1/n, 1/n, \ldots, 1/n)^\top$ to fit all the columns. One can use c to approximate a with cost at most $(n-1) \cdot n^{3/4}/n = \Theta(n^{3/4})$ by matching the first coordinate, while one can use c to approximate b with cost at most $1/n^{1/4}$ by matching the last $n-1$ coordinates, and since there are $n-1$ columns equal to b, the overall total cost of using c to approximate matrix A is $\Theta(n^{3/4})$.

□

Chapter 21

Tensor Low Rank Approximation

We consider relative error low rank approximation of *tensors* with respect to the Frobenius norm. Namely, given an order-q tensor $A \in \mathbb{R}^{\prod_{i=1}^{q} n_i}$, output a rank-$k$ tensor B for which $\|A - B\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}$, where $\mathrm{OPT} = \inf_{\text{rank-}k\ A'} \|A - A'\|_F^2$. Despite much success on obtaining relative error low rank approximations for matrices, no such results were known for tensors for arbitrary $(1+\epsilon)$-approximations. One structural issue is that there may be no rank-k tensor A_k achieving the above infinum. Another, computational issue, is that an efficient relative error low rank approximation algorithm for tensors would allow one to compute the rank of a tensor, which is NP-hard. We bypass these two issues via (1) bicriteria and (2) parameterized complexity solutions:

1. We give an algorithm which outputs a rank $k' = O((k/\epsilon)^{q-1})$ tensor B for which $\|A - B\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}$ in $\mathrm{nnz}(A) + n \cdot \mathrm{poly}(k/\epsilon)$ time in the real RAM model, whenever either A_k exists or $\mathrm{OPT} > 0$. Here $\mathrm{nnz}(A)$ denotes the number of non-zero entries in A. If both A_k does not exist and $\mathrm{OPT} = 0$, then B instead satisfies $\|A - B\|_F^2 < \gamma$, where γ is any positive, arbitrarily small function of n.

2. We give an algorithm for any $\delta > 0$ which outputs a rank k tensor B for which $\|A - B\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}$ and runs in $(\mathrm{nnz}(A) + n\,\mathrm{poly}(k/\epsilon) + \exp(k^2/\epsilon)) \cdot n^{\delta}$ time in the unit cost RAM model, whenever $\mathrm{OPT} > 2^{-O(n^{\delta})}$ and there is a rank-k tensor $B =$

$\sum_{i=1}^{k} u_i \otimes v_i \otimes w_i$ for which $\|A-B\|_F^2 \leq (1+\epsilon/2)\,\mathrm{OPT}$ and $\|u_i\|_2, \|v_i\|_2, \|w_i\|_2 \leq 2^{O(n^\delta)}$. If $\mathrm{OPT} \leq 2^{-\Omega(n^\delta)}$, then B instead satisfies $\|A-B\|_F^2 \leq 2^{-\Omega(n^\delta)}$.

Our first result is polynomial time, and in fact input sparsity time, in n, k, and $1/\epsilon$, for any $k \geq 1$ and any $0 < \epsilon < 1$, while our second result is fixed parameter tractable in k and $1/\epsilon$. For outputting a rank-k tensor, or even a bicriteria solution with rank-Ck for a certain constant $C > 1$, we show a $2^{\Omega(k^{1-o(1)})}$ time lower bound under the Exponential Time Hypothesis.

Our results are based on an "iterative existential argument", and also give the first relative error low rank approximations for tensors for a large number of error measures for which nothing was known. In particular, we give the first relative error approximation algorithms on tensors for: column row and tube subset selection, entrywise ℓ_p-low rank approximation for $1 \leq p < 2$, low rank approximation with respect to sum of Euclidean norms of faces or tubes, weighted low rank approximation, and low rank approximation in distributed and streaming models. We also obtain several new results for matrices, such as $\mathrm{nnz}(A)$-time CUR decompositions, improving the previous $\mathrm{nnz}(A)\log n$-time CUR decompositions, which may be of independent interest.

21.1 Introduction

Low rank approximation of matrices is one of the most well-studied problems in randomized numerical linear algebra. Given an $n \times d$ matrix A with real-valued entries, we want to output a rank-k matrix B for which $\|A - B\|$ is small, under a given norm. While this problem can be solved exactly using the singular value decomposition for some norms like the spectral and Frobenius norms, the time complexity is still $\min(nd^{\omega-1}, dn^{\omega-1})$, where $\omega \approx 2.373$ is the exponent of matrix multiplication [Str69, CW87, Wil12, LG14]. This time complexity is prohibitive when n and d are large. By now there are a number of approximation algorithms for this problem, with the Frobenius norm [1] being one of the most common error measures. Initial solutions [FKV04, AM07] to this problem were based on sampling and achieved additive error in terms of $\epsilon\|A\|_F$, where $\epsilon > 0$ is an approximation parameter, which can be arbitrarily larger than the optimal cost $\mathrm{OPT} = \min_{\text{rank-}k\ B} \|A - B\|_F^2$. Since then a number of solutions based on the technique of oblivious sketching [Sar06, CW13, MM13, NN13a] as well as sampling based on non-uniform distributions [DMM06c, DMM06b, DMM08, DMIMW12], have been proposed which achieve the stronger notion of *relative error*, namely, which output a rank-k matrix B for which $\|A - B\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}$ with high probability. It is now known how to output a factorization of such a $B = U \cdot V$, where U is $n \times k$ and V is $k \times d$, in $\mathrm{nnz}(A) + (n+d)\,\mathrm{poly}(k/\epsilon)$ time [CW13, MM13, NN13a]. Such an algorithm is optimal, up to the $\mathrm{poly}(k/\epsilon)$ factor, as any algorithm achieving relative error must read almost all of the entries.

Tensors are often more useful than matrices for capturing higher order relations

[1] Recall the Frobenius norm $\|A\|_F$ of a matrix A is $(\sum_{i=1}^{n}\sum_{j=1}^{d} A_{i,j}^2)^{1/2}$.

in data. Computing low rank factorizations of approximations of tensors is the primary task of interest in a number of applications, such as in psychology[Kro83], chemometrics [Paa00, SBG04], neuroscience [AAB+07, KB09, CLK+15], computational biology [CV15, SC15], natural language processing [CYYM14, LZBJ14, LZMB15, BNR+15], computer vision [VT02, WA03, SH05, HPS05, HD08, AFdLGTL09, PLY10, LFC+16, CLZ17], computer graphics [VT04, WWS+05, Vas09], security [AÇKY05, ACY06, KB06], cryptography [FS99, Sch12, KYFD15, SHW+16] data mining [KS08, RST10, KABO10, Mør11], machine learning applications such as learning hidden Markov models, reinforcement learning, community detection, multi-armed bandit, ranking models, neural network, Gaussian mixture models and Latent Dirichlet allocation [MR05, AFH+12, HK13, ALB13, ABSV14, AGH+14, AGHK14, BCV14, JO14a, GHK15, PBLJ15, JSA15, ALA16, AGMR16, ZSJ+17], programming languages [RTP16], signal processing [Wes94, DLDM98, Com09, CMDL+15], and other applications [YCS11, LMWY13, OS14, ZCZJ14, STLS14, YCS16, RNSS16].

Despite the success for matrices, the situation for order-q tensors for $q > 2$ is much less understood. There are a number of works based on alternating minimization [CC70, Har70, FMPS13, FT15, ZG01, BS15] gradient descent or Newton methods [ES09, ZG01], methods based on the Higher-order SVD (HOSVD) [LMV00a] which provably incur $\Omega(\sqrt{n})$-inapproximability for Frobenius norm error [LMV00b], the power method or orthogonal iteration method [LMV00b], additive error guarantees in terms of the flattened (unfolded) tensor rather than the original tensor [MMD08], tensor trains [Ose11], the tree Tucker decomposition [OT09], or methods specialized to orthogonal tensors [KM11, AGH+14, MHG15, WTSA15, WA16, SWZ16]. There are also a number of works on the problem of tensor completion, that is, recovering a low rank tensor from missing entries [WM01, AKDM10,

TSHK11, LMWY13, MHWG14, JO14b, BM16]. There is also another line of work using the sum of squares (SOS) technique to study tensor problems [BKS15a, GM15, HSS15, HSSS16, MSS16, PS17, SS17], other recent work on tensor PCA [All12b, All12a, RM14, JMZ15, ADGM16, ZX17], and work applying smoothed analysis to tensor decomposition [BCMV14]. Several previous works also consider more robust norms than the Frobenius norm for tensors, e.g., the R_1 norm (ℓ_1-ℓ_2-ℓ_2 norm in our work) [HD08], ℓ_1-PCA [PLY10], entry-wise ℓ_1 regularization [GGH14], M-estimator loss [YFS16], weighted approximation [Paa97, TK11, LRHG13], tensor-CUR [OST08, MMD08, CC10, FMMN11, FT15], or robust tensor PCA [GQ14, LFC+16, CLZ17].

Some of the above works, such as ones based on the tensor power method or alternating minimization, require incoherence or orthogonality assumptions. Others, such as those based on the simultaneous SVD, require an assumption on the minimum singular value. See the monograph of Moitra [Moi14a] for further discussion. Unlike the situation for matrices, there is no work for tensors that is able to achieve the following natural relative error guarantee: given a q-th order tensor $A \in \mathbb{R}^{n^{\otimes q}}$ and an arbitrary accuracy parameter $\epsilon > 0$, output a rank-k tensor B for which

$$\|A - B\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}, \tag{21.1}$$

where $\mathrm{OPT} = \inf_{\text{rank-}k\ B'} \|A - B'\|_F^2$, and where recall the rank of a tensor B is the minimal integer k for which B can be expressed as $\sum_{i=1}^k U_1^i \otimes U_2^i \otimes \cdots \otimes U_q^i$. General speaking, a q-th order tensor can have rank at most n^{q-1}. A third order tensor, for example, has rank which is an integer in $\{0, 1, 2, \ldots, n^2\}$. We note that [BCV14] is able to achieve a relative error 5-approximation for third order tensors, and an $O(q)$-approximation for q-th order tensors,

though it cannot achieve a $(1+\epsilon)$-approximation. We compare our work to [BCV14] in Section 21.1.4 below.

For notational simplicity, we will start by assuming third order tensors with all dimensions of equal size, but we extend all of our main theorems below to tensors of any constant order $q > 3$ and dimensions of different sizes.

The first caveat regarding (21.1) for tensors is that an optimal rank-k solution may not even exist! This is a well-known problem for tensors (see, e.g., [KHL89, Paa00, KDS08, Ste06, Ste08] and more details in section 4 of [DSL08]), for which for any rank-k tensor B, there always exists another rank-k tensor B' for which $\|A-B'\|_F^2 < \|A-B\|_F^2$. If $\mathrm{OPT} = 0$, then in this case for any rank-k tensor B, necessarily $\|A-B\|_F^2 > 0$, and so (21.1) cannot be satisfied. This fact was known to algebraic geometers as early as the 19th century, which they refer to as the fact that the locus of r-th secant planes to a Segre variety may not define a (closed) algebraic variety [DSL08, Lan12]. It is also known as the phenomenon underlying the concept of *border rank*[2][Bin80, Bin86, BCS97, Knu98, Lan06]. In this case it is natural to allow the algorithm to output an arbitrarily small $\gamma > 0$ amount of additive error. Note that unlike several additive error algorithms for matrices, the additive error here can in fact be an arbitrarily small positive function of n. If, however, $\mathrm{OPT} > 0$, then for any $\epsilon > 0$, there exists a rank-k tensor B for which $\|A-B\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}$, and in this case we should still require the algorithm to output a relative-error solution. If an optimal rank-k solution B exists, then as for matrices, it is natural to require the algorithm to output a relative-error solution.

[2] https://en.wikipedia.org/wiki/Tensor_rank_decomposition#Border_rank

Besides the above definitional issue, a central reason that (21.1) has not been achieved is that computing the rank of a third order tensor is well-known to be NP-hard [Hås90, HL13]. Thus, if one had such a polynomial time procedure for solving the problem above, one could determine the rank of A by running the procedure on each $k \in \{0, 1, 2, \ldots, n^2\}$, and check for the first value of k for which $\|A - B\|_F^2 = 0$, thus determining the rank of A. However, it is unclear if approximating the tensor rank is hard. This question will also be answered in this work.

The main question which we address is how to define a meaningful notion of (21.1) for the case of tensors and whether it is possible to obtain provably efficient algorithms which achieve this guarantee, without any assumptions on the tensor itself. Besides (21.1), there are many other notions of relative error for low rank approximation of matrices for which provable guarantees for tensors are unknown, such as tensor CURT, R_1 norm, and the weighted and ℓ_1 norms mentioned above. Our goal is to provide a general technique to obtain algorithms for many of these variants as well.

21.1.1 Our Results

To state our results, we first consider the case when a rank-k solution A_k exists, that is, there exists a rank-k tensor A_k for which $\|A - A_k\|_F^2 = \text{OPT}$.

We first give a $\text{poly}(n, k, 1/\epsilon)$-time $(1+\epsilon)$-relative error approximation algorithm for any $0 < \epsilon < 1$ and any $k \geq 1$, but allow the output tensor B to be of rank $O((k/\epsilon)^2)$ (for general q-order tensors, the output rank is $O((k/\epsilon)^{q-1})$, whereas we measure the cost of B with respect to rank-k tensors. Formally, $\|A - B\|_F^2 \leq (1+\epsilon)\|A - A_k\|_F^2$. In fact, our algorithm can be implemented in $\text{nnz}(A) + n \cdot \text{poly}(k/\epsilon)$ time in the real-RAM model, where $\text{nnz}(A)$ is the number of non-zero entries of A. Since it is necessary to use $\text{nnz}(A)$ time to avoid missing any (large) entry, such an algorithm is optimal (for running time) for any relative error algorithm, even bicriteria ones.

If A_k does not exist, then our output B instead satisfies $\|A - B\|_F^2 \leq (1+\epsilon)\,\text{OPT} + \gamma$, where γ is an arbitrarily small additive error. Since γ is arbitrarily small, $(1+\epsilon)\,\text{OPT} + \gamma$ is still a relative error whenever $\text{OPT} > 0$. Our theorem is as follows.

Theorem 21.1.1 (A Version of Theorem 21.4.9, bicriteria)**.** *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, if A_k exists then there is a randomized algorithm running in $\text{nnz}(A) + n \cdot \text{poly}(k/\epsilon)$ time which outputs a (factorization of a) rank-$O(k^2/\epsilon^2)$ tensor B for which $\|A - B\|_F^2 \leq (1+\epsilon)\|A - A_k\|_F^2$. If A_k does not exist, then the algorithm outputs a rank-$O(k^2/\epsilon^2)$ tensor B for which $\|A - B\|_F^2 \leq (1+\epsilon)\,\text{OPT} + \gamma$, where $\gamma > 0$ is an arbitrarily small positive function of n. In both cases, the success probability is at least $2/3$.*

One of the main applications of matrix low rank approximation is parameter reduction, as one can store the matrix using fewer parameters in factored form or more quickly

multiply by the matrix if given in factored form, as well as remove directions that correspond to noise. In such applications, it is not essential that the low rank approximation have rank exactly k, since one still has a significant parameter reduction with a matrix of slightly larger rank. This same motivation applies to tensor low rank approximation; we obtain both space and time savings by representing a tensor in factored form, and in such applications bicriteria applications suffice. Moreover, the extremely efficient $\text{nnz}(A) + n \cdot \text{poly}(k/\epsilon)$ time algorithm we obtain may outweigh the need for outputting a tensor of rank exactly k. Bicriteria algorithms are common for coping with hardness; see e.g., results on robust low rank approximation of matrices [DV07, FFSS07, CW15a], sparse recovery [CKPS16], clustering [MMSW15, HT16], and approximation algorithms more generally.

We note that there are other applications, such as unique tensor decomposition in the method of moments, see, e.g., [BCV14], where one may have a hard rank constraint of k for the output. However, in such applications the so-called Tucker decomposition is still a useful dimensionality-reduction analogue of the SVD and our techniques for proving

We next consider the case when the rank parameter k is small, and we try to obtain rank-k solutions which are efficient for small values of k. As before, we first suppose that A_k exists.

If $A_k = \sum_{i=1}^{k} u_i \otimes v_i \otimes w_i$ and the norms $\|u_i\|_2$, $\|v_i\|_2$, and $\|w_i\|_2$ are bounded by $2^{\text{poly}(n)}$, we can return a rank-k solution B for which $\|A - B\|_F^2 \leq (1+\epsilon)\|A - A_k\|_F^2 + 2^{-\text{poly}(n)}$, in $f(k, 1/\epsilon) \cdot \text{poly}(n)$ time in the standard unit cost RAM model with words of size $O(\log n)$ bits. Thus, our algorithm is *fixed parameter tractable* in k and $1/\epsilon$, and in fact remains polynomial time for any values of k and $1/\epsilon$ for which $k^2/\epsilon = O(\log n)$. This is motivated by a number of low rank approximation applications in which k is typically small. The additive error of

$2^{-\operatorname{poly}(n)}$ is only needed in order to write down our solution B in the unit cost RAM model, since in general the entries of B may be irrational, even if the entries of A are specified by $\operatorname{poly}(n)$ bits. If instead we only want to output an approximation to the value $\|A - A_k\|_F^2$, then we can output a number Z for which $\operatorname{OPT} \leq Z \leq (1+\epsilon)\operatorname{OPT}$, that is, we do not incur additive error.

When A_k does not exist, there still exists a rank-k tensor $\widetilde{A}$ for which $\|A - \widetilde{A}\|_F^2 \leq \operatorname{OPT} + \gamma$, for arbitrary $\gamma > 0$. We require there exists such a $\widetilde{A}$ for which if $\widetilde{A} = \sum_{i=1}^{k} u_i \otimes v_i \otimes w_i$, then the norms $\|u_i\|_2$, $\|v_i\|_2$, and $\|w_i\|_2$ are bounded by $2^{\operatorname{poly}(n)}$.

The assumption in the previous two paragraphs that the factors of A_k and of $\widetilde{A}$ have norm bounded by $2^{\operatorname{poly}(n)}$ is necessary in certain cases, e.g., if $\operatorname{OPT} = 0$ and we are to write down the factors in $\operatorname{poly}(n)$ time. An abridged version of our theorem is as follows.

Theorem 21.1.2 (Combination of Theorem 21.4.1 and 21.4.2, rank-k)**.** *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $\delta > 0$, if $A_k = \sum_{i=1}^{k} u_i \otimes v_i \otimes w_i$ exists and each of $\|u_i\|_2, \|v_i\|_2$, and $\|w_i\|_2$ is bounded by $2^{O(n^\delta)}$, then there is a randomized algorithm running in $O(\operatorname{nnz}(A) + n\operatorname{poly}(k, 1/\epsilon) + 2^{O(k^2/\epsilon)}) \cdot n^\delta$ time in the unit cost* RAM *model with words of size $O(\log n)$ bits[3], which outputs a (factorization of a) rank-k tensor B for which $\|A - B\|_F^2 \leq (1+\epsilon)\|A - A_k\|_F^2 + 2^{-O(n^\delta)}$. Further, we can output a number Z for which $\operatorname{OPT} \leq Z \leq (1+\epsilon)\operatorname{OPT}$ in the same amount of time. When A_k does not exist, if there exists a rank-k tensor $\widetilde{A}$ for which $\|A - \widetilde{A}\|_F^2 \leq \operatorname{OPT} + 2^{-O(n^\delta)}$ and $\widetilde{A} = \sum_{i=1}^{k} u_i \otimes v_i \otimes w_i$ is such that the norms $\|u_i\|_2$, $\|v_i\|_2$, and $\|w_i\|_2$ are bounded by $2^{O(n^\delta)}$, then we can output a (factorization of a) rank-k tensor $\widetilde{A}$ for which $\|A - \widetilde{A}\|_F^2 \leq (1+\epsilon)\operatorname{OPT} + 2^{-O(n^\delta)}$.*

[3]The entries of A are assumed to fit in n^δ words.

Our techniques for proving Theorem 21.1.1 and Theorem 21.1.2 open up avenues for many other problems in linear algebra on tensors. We now define the problems and state our results for them.

There is a long line of research on matrix column subset selection and CUR decomposition [DMM08, BMD09, DR10, BDM11, FEGK13, BW14, WS15, ABF+16, SWZ17] under operator, Frobenius, and entry-wise ℓ_1 norm. It is natural to consider tensor column subset selection or tensor-CURT[4], however most previous works either give error bounds in terms of the tensor flattenings [DMM08], assume the original tensor has certain properties [OST08, FT15, TM17], consider the exact case which assumes the tensor has low rank [CC10], or only fit a high dimensional cross-shape to the tensor rather than to all of its entries [FMMN11]. Such works are not able to provide a $(1+\epsilon)$-approximation guarantee as in the matrix case without assumptions. We consider tensor column, row, and tube subset selection, with the goal being to find three matrices: a subset $C \in \mathbb{R}^{n\times c}$ of columns of A, a subset $R \in \mathbb{R}^{n\times r}$ of rows of A, and a subset $T \in \mathbb{R}^{n\times t}$ of tubes of A, such that there exists a tensor $U \in \mathbb{R}^{c\times r\times t}$ for which

$$\|U(C,R,T) - A\|_\xi \leq \alpha\|A_k - A\|_\xi + \gamma, \tag{21.2}$$

where $\gamma = 0$ if A_k exists and $\gamma = 2^{-\mathrm{poly}(n)}$ otherwise, $\alpha > 1$ is the approximation ratio, ξ is either Frobenius norm or Entry-wise ℓ_1 norm, and $U(C,R,T) = \sum_{i=1}^{c}\sum_{j=1}^{r}\sum_{l=1}^{t} U_{i,j,l}\cdot C_i \otimes R_j \otimes T_l$. In tensor CURT decomposition, we also want to output U.

We provide a (nearly) input sparsity time algorithm for this, together with an alternative input sparsity time algorithm which chooses slightly larger factors C, R, and T.

[4]T denotes the tube which is the column in 3rd dimension of tensor.

To do this, we combine Theorem 21.1.1 with the following theorem which, given a factorization of a rank-k tensor B, obtains C, U, R, and T in terms of it:

Theorem 21.1.3 (Combination of Theorem 21.4.39 and 21.4.40, $\|\|\|_F$-norm, CURT decomposition)**.** *Given a 3rd order tensor $A \in \mathbb{R}^{n\times n\times n}$, let $k \geq 1$, and let $U_B, V_B, W_B \in \mathbb{R}^{n\times k}$ be given. There is an algorithm running in $O(\mathrm{nnz}(A)\log n) + \widetilde{O}(n^2)\,\mathrm{poly}(k, 1/\epsilon)$ time (respectively, $O(\mathrm{nnz}(A)) + n\,\mathrm{poly}(k, 1/\epsilon)$ time) which outputs a subset $C \in \mathbb{R}^{n\times c}$ of columns of A, a subset $R \in \mathbb{R}^{n\times r}$ of rows of A, a subset $T \in \mathbb{R}^{n\times t}$ of tubes of A, together with a tensor $U \in \mathbb{R}^{c\times r\times t}$ with $\mathrm{rank}(U) = k$ such that $c = r = t = O(k/\epsilon)$ (respectively, $c = r = t = O(k\log k + k/\epsilon)$), and $\|U(C, R, T) - A\|_F^2 \leq (1+\epsilon)\|U_B \otimes V_B \otimes W_B - A\|_F^2$ holds with probability at least $9/10$.*

Combining Theorems 21.1.2 and 21.1.3 (with B being a $(1 + O(\epsilon))$-approximation to A) we achieve Equation (21.2) with $\alpha = (1 + \epsilon)$ and $\xi = F$ with the *optimal* number of columns, rows, tubes, and rank of U (we mention our matching lower bound later), though the running time has an $2^{O(k^2/\epsilon)}$ term in it. We note that instead combining Theorem 21.1.1 and Theorem 21.1.3 gives a bicriteria result for CURT without a $2^{O(k^2/\epsilon)}$ term in the running time, though it is suboptimal in the number of columns, rows, tubes, and rank of U.

As a side result worth stating, our analysis improves the best matrix CUR decomposition algorithm under Frobenius norm [BW14], providing the first optimal $\mathrm{nnz}(A)$-time algorithm:

Theorem 21.1.4 (Informal Version of Theorem 21.6.1, Matrix CUR decomposition)**.** *There is an algorithm, which given a matrix $A \in \mathbb{R}^{n\times d}$ and an integer $k \geq 1$, runs in $O(\mathrm{nnz}(A)) + (n + d)\,\mathrm{poly}(k, 1/\epsilon)$ time and outputs three matrices: $C \in \mathbb{R}^{n\times c}$ containing c columns of A,*

$R \in \mathbb{R}^{r \times d}$ *containing* r *rows of* A*, and* $U \in \mathbb{R}^{c \times r}$ *with* $\operatorname{rank}(U) = k$ *for which* $r = c = O(k/\epsilon)$ *and* $\|CUR - A\|_F^2 \leq (1+\epsilon) \min_{\operatorname{rank}-k \ A_k} \|A_k - A\|_F^2$*, holds with probability at least* $9/10$*.*

21.1.2 Our Techniques

Many of our proofs, in particular those for Theorem 21.1.1 and Theorem 21.1.2, are based on what we call an "iterative existential proof", which we then turn into an algorithm in two different ways depending if we are proving Theorem 21.1.1 or Theorem 21.1.2.

Henceforth, we assume A_k exists; otherwise replace A_k with a suitably good tensor $\widetilde{A}$ in what follows. Since $A_k = \sum_{i=1}^{k} U_i^* \otimes V_i^* \otimes W_i^*$[5], we can create three $n \times k$ matrices U^*, V^*, and W^* whose columns are the vectors U_i^*, V_i^*, and W_i^*, respectively. Now we consider the three different flattenings (or unfoldings) of A_k, which express A_k as an $n \times n^2$ matrix. Namely, by thinking of A_k as the sum of outer products, we can write the three flattenings of A_k as $U^* \cdot Z_1$, $V^* \cdot Z_2$, and $W^* \cdot Z_3$, where the rows of Z_1 are $\mathrm{vec}(V_i^* \otimes W_i^*)$ [6] (For simplicity, we write $Z_1 = (V^{*\top} \odot W^{*\top})$. [7]), the rows of Z_2 are $\mathrm{vec}(U_i^* \otimes W_i^*)$, and the rows of Z_3 are $\mathrm{vec}(U_i^* \otimes V_i^*)$, for $i \in [k] \stackrel{\text{def}}{=} \{1, 2, \ldots, k\}$. Letting the three corresponding flattenings of the input tensor A be A_1, A_2, and A_3, by the symmetry of the Frobenius norm, we have $\|A - B\|_F^2 = \|A_1 - U^* Z_1\|_F^2 = \|A_2 - V^* Z_2\|_F^2 = \|A_3 - W^* Z_3\|_F^2$.

Let us consider the hypothetical regression problem $\min_U \|A_1 - U Z_1\|_F^2$. Note that we do not know Z_1, but we will not need to. Let $r = O(k/\epsilon)$, and suppose S_1 is an $n^2 \times r$ matrix of i.i.d. normal random variables with mean 0 and variance $1/r$, denoted $N(0, 1/r)$. Then by standard results for regression (see, e.g., [Woo14b] for a survey), if $\widehat{U}$ is the minimizer to

[5] For simplicity, we define $U \otimes V \otimes W = \sum_{i=1}^{k} U_i \otimes V_i \otimes W_i$, where U_i is the i-th column of U.

[6] $\mathrm{vec}(V_i^* \otimes W_i^*)$ denotes a row vector that has length $n_1 n_2$ where V_i^* has length n_1 and W_i^* has length n_2.

[7] $(V^{*\top} \odot W^{*\top})$ denotes a $k \times n_1 n_2$ matrix where the i-th row is $\mathrm{vec}(V_i^* \otimes W_i^*)$, where length n_1 vector V_i^* is the i-th column of $n_1 \times k$ matrix V^*, and length n_2 vector W_i^* is the i-th column of $n_2 \times k$ matrix W^*, $\forall i \in [k]$.

the smaller regression problem $\widehat{U} = \text{argmin}_U \|UZ_1S_1 - A_1S_1\|_F^2$, then

$$\|A_1 - \widehat{U}Z_1\|_F^2 \leq (1+\epsilon)\text{min}_U\|A_1 - UZ_1\|_F^2. \tag{21.3}$$

Moreover,$\widehat{U} = A_1S_1(Z_1S_1)^\dagger$. Although we do not know know Z_1, this implies $\widehat{U}$ is in the column span of A_1S_1, which we do know, since we can flatten A to compute A_1 and then compute A_1S_1. Thus, this hypothetical regression argument gives us an existential statement - there exists a good rank-k matrix $\widehat{U}$ in the column span of A_1S_1. We could similarly define $\widehat{V} = A_2S_2(Z_2S_2)^\dagger$ and $\widehat{W} = A_3S_3(Z_3S_3)^\dagger$ as solutions to the analogous regression problems for the other two flattenings of A, which are in the column spans of A_2S_2 and A_3S_3, respectively. Given A_1S_1, A_2S_2, and A_3S_3, which we know, we could hope there is a good rank-k tensor in the span of the rank-1 tensors

$$\{(A_1S_1)_a \otimes (A_2S_2)_b \otimes (A_3S_3)_c\}_{a,b,c\in[r]}. \tag{21.4}$$

However, an immediate issue arises. First, note that our hypothetical regression problem guarantees that $\|A_1 - \widehat{U}Z_1\|_F^2 \leq (1+\epsilon)\|A - A_k\|_F^2$, and therefore since the rows of Z_1 are of the special form $\text{vec}(V_i^* \otimes W_i^*)$, we can perform a "retensorization" to create a rank-k tensor $B = \sum_i \widehat{U}_i \otimes V_i^* \otimes W_i^*$ from the matrix $\widehat{U}Z_1$ for which $\|A - B\|_F^2 \leq (1+\epsilon)\|A - A_k\|_F^2$. While we do not know $\widehat{U}$, since it is in the column span of A_1S_1, it implies that B is in the span of the rank-1 tensors $\{(A_1S_1)_a \otimes V_b^* \otimes W_c^*\}_{a\in[r],b,c\in[k]}$. Analogously, we have that there is a good rank-k tensor B in the span of the rank-1 tensors $\{U_a^* \otimes (A_2S_2)_b \otimes W_c^*\}_{a,c\in[k],b\in[r]}$, and a good rank-$k$ tensor B in the span of the rank-1 tensors $\{U_a^* \otimes V_b^* \otimes (A_3S_3)_c\}_{a,b\in[k],c\in[r]}$. However, we do not know U^* or V^*, and it is not clear there is a rank-k tensor B for which *simultaneously* its first factors are in the column span of A_1S_1, its second factors are in the

column span of A_2S_2, and its third factors are in the column span of A_3S_3, i.e., whether there is a good rank-k tensor B in the span of rank-1 tensors in (21.4).

We fix this by an iterative argument. Namely, we first compute A_1S_1, and write $\widehat{U} = A_1S_1(Z_1S_1)^\dagger$. We now redefine Z_2 *with respect to* $\widehat{U}$, so the rows of Z_2 are $\mathrm{vec}(\widehat{U}_i \otimes W_i^*)$ for $i \in [k]$, and consider the regression problem $\min_V \|A_2 - VZ_2\|_F^2$. While we do not know Z_2, if S_2 is an $n^2 \times r$ matrix of i.i.d. Gaussians, we again have the statement that $\widehat{V} = A_2S_2(Z_2S_2)^\dagger$ satisfies

$$\begin{aligned}
\|A_2 - \widehat{V}Z_2\|_F^2 &\leq (1+\epsilon)\min_V \|A_2 - VZ_2\|_F^2 \text{ by the regression guarantee with Gaussians} \\
&\leq (1+\epsilon)\|A_2 - V^*Z_2\|_F^2 \text{ since } V^* \text{ is no better than the minimizer } V \\
&= (1+\epsilon)\|A_1 - \widehat{U}Z_1\|_F^2 \text{ by retensorizing and flattening along a different dimension} \\
&\leq (1+\epsilon)^2\min_U \|A_1 - UZ_1\|_F^2 \text{ by (21.3)} \\
&= (1+\epsilon)^2\|A - A_k\|_F^2 \text{ by definition of } Z_1 \ .
\end{aligned}$$

Now we can retensorize $\widehat{V}Z_2$ to obtain a rank-k tensor B for which $\|A - B\|_F^2 = \|A_2 - \widehat{V}Z_2\|_F^2 \leq (1+\epsilon)^2\|A - A_k\|_F^2$. Note that since the columns of $\widehat{V}$ are in the span of A_2S_2, and the rows of Z_2 are $\mathrm{vec}(\widehat{U}_i \otimes W_i^*)$ for $i \in [k]$, where the columns of $\widehat{U}$ are in the span of A_1S_1, it follows that B is in the span of rank-1 tensors $\{(A_1S_1)_a \otimes (A_2S_2)_b \otimes \widehat{V}_c\}_{a,b\in[r],c\in[k]}$.

Suppose we now redefine Z_3 so that it is now an $r^2 \times n^2$ matrix with rows $\mathrm{vec}((A_1S_1)_a \otimes (A_2S_2)_b)$ for all pairs $a, b \in [r]$, and consider the regression problem $\min_W \|A_3 - WZ_3\|_F^2$. Now observe that since *we know* Z_3, and since we can form A_3 by flattening A, we can solve for $W \in \mathbb{R}^{n \times r^2}$ in polynomial time by solving a regression problem. Retensorizing WZ_3 to a tensor B, it follows that we have found a rank-$r^2 = O(k^2/\epsilon^2)$ tensor B for which

$\|A - B\|_F^2 \leq (1+\epsilon)^2 \|A - A_k\|_F^2 = (1 + O(\epsilon))\|A - A_k\|_F^2$, and the result follows by adjusting ϵ by a constant factor.

To obtain the $\text{nnz}(A) + n\,\text{poly}(k/\epsilon)$ running time guarantee of Theorem 21.1.1, while we can replace S_1 and S_2 with compositions of a sparse CountSketch matrix and a Gaussian matrix (see chapter 2 of [Woo14b] for a survey), enabling us to compute $A_1 S_1$ and $A_2 S_2$ in $\text{nnz}(A) + n\,\text{poly}(k/\epsilon)$ time, we still need to solve the regression problem $\min_W \|A_3 - W Z_3\|_F^2$ quickly, and note that we cannot even write down Z_3 without spending $r^2 n^2$ time. Here we use a different random matrix S_3 called TensorSketch, which was introduced in [Pag13, PP13], but for which we will need the stronger properties of a subspace embedding and approximate matrix product shown to hold for it in [ANW14]. Given the latter properties, we can instead solve the regression problem $\min_W \|A_3 S_3 - W Z_3 S_3\|_F^2$, and importantly $A_3 S_3$ and $Z_3 S_3$ can be computed in $\text{nnz}(A) + n\,\text{poly}(k/\epsilon)$ time. Finally, this small problem can be solved in $n\,\text{poly}(k/\epsilon)$ time.

If we want to output a rank-k solution as in Theorem 21.1.2, then we need to introduce indeterminates at several places in the preceding argument and run a generic polynomial optimization procedure which runs in time exponential in the number of indeterminates. Namely, we write $\widehat{U}$ as $A_1 S_1 X_1$, where X_1 is an $r \times k$ matrix of indeterminates, we write $\widehat{V}$ as $A_2 S_2 X_2$, where X_2 is an $r \times k$ matrix of indeterminates, and we write $\widehat{W}$ as $A_3 S_3 X_3$, where X_3 is an $r \times k$ matrix of indeterminates. When executing the above iterative argument, we let the rows of Z_1 be the vectors $\text{vec}(V_i^* \otimes W_i^*)$, the rows of Z_2 be the vectors $\text{vec}(\widehat{U}_i \otimes W_i^*)$, and the rows of Z_3 be the vectors $\text{vec}(\widehat{U}_i \otimes V_i)$. Then $\widehat{U}$ is a $(1+\epsilon)$-approximate minimizer to $\min_U \|A_1 - U Z_1\|_F$, while $\widehat{V}$ is a $(1+\epsilon)$-approximate minimizer to $\min_V \|A_2 - V Z_2\|_F$, while $\widehat{W}$ is a $(1+\epsilon)$-approximate minimizer to $\min_W \|A_3 - W Z_3\|_F$. Note that by assigning

$X_1 = (Z_1S_1)^\dagger$, $X_2 = (Z_2S_2)^\dagger$, and $X_3 = (Z_3S_3)^\dagger$, it follows that the rank-k tensor $B = \sum_{i=1}^k (A_1S_1X_1)_i \otimes (A_2S_2X_2)_i \otimes (A_3S_3X_3)_i$ satisfies $\|A-B\|_F^2 \leq (1+\epsilon)^3\|A-A_k\|_F^2$, as desired. Note that here the rows of Z_2 are a function of X_1, while the rows of Z_3 are a function of both X_1 and X_2. What is important for us though is that it suffices to minimize the degree-6 polynomial $\sum_{a,b,c\in[n]}(\sum_{i=1}^k (A_1S_1X_1)_{a,i} \cdot (A_2S_2X_2)_{b,i} \cdot (A_3S_3X_3)_{c,i} - A_{a,b,c})^2$, over the $3rk = O(k^2/\epsilon)$ indeterminates X_1, X_2, X_3, since we know there exists an assignment to X_1, X_2, and X_3 providing a $(1 + O(\epsilon))$-approximate solution, and any solution X_1, X_2, and X_3 found by minimizing the above polynomial will be no worse than that solution. This polynomial can be minimized up to additive $2^{-\operatorname{poly}(n)}$ additive error in $\operatorname{poly}(n)$ time [Ren92a, BPR96] assuming the entries of U^*, V^*, and W^* are bounded by $2^{\operatorname{poly}(n)}$, as assumed in Theorem 21.1.2. Similar arguments can be made for obtaining a relative error approximation to the OPT as well as handling the case when A_k does not exist.

To optimize the running time to $\operatorname{nnz}(A)$, we can choose CountSketch matrices T_1, T_2, T_3 of $t = \operatorname{poly}(k, 1/\epsilon) \times n$ dimensions and reapply the above iterative argument. Then it suffices to minimize this small size degree-6 polynomial $\sum_{a,b,c\in[t]}(\sum_{i=1}^k (T_1A_1S_1X_1)_{a,i} \cdot (T_2A_2S_2X_2)_{b,i} \cdot (T_3A_3S_3X_3)_{c,i} - (A(T_1, T_2, T_3))_{a,b,c})^2$, over the $3rk = O(k^2/\epsilon)$ indeterminates X_1, X_2, X_3. Outputting $A_1S_1X_1$, $A_2S_2X_2$, $A_3S_3X_3$ then provides a $(1 + \epsilon)$-approximate solution.

Our iterative existential argument provides a general framework for obtaining low rank approximation results for tensors for many other error measures as well.

21.1.3 Other Low Rank Approximation Algorithms Following Our Framework.

Column, row, tube subset selection, and CURT decomposition. In tensor column, row, tube subset selection, the goal is to find three matrices: a subset C of columns of A, a subset R of rows of A, and a subset T of tubes of A, such that there exists a small tensor U for which $\|U(C,R,T)-A\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}$. We first choose two Gaussian matrices S_1 and S_2 with $s_1 = s_2 = O(k/\epsilon)$ columns, and form a matrix $Z_3' \in \mathbb{R}^{(s_1 s_2)\times n^2}$ with (i,j)-th row equal to the vectorization of $(A_1S_1)_i \otimes (A_2S_2)_j$. Motivated by the regression problem $\min_W \|A_3 - WZ_3'\|_F$, we sample $d_3 = O(s_1 s_2/\epsilon)$ columns from A_3 and let D_3 denote this selection matrix. There are a few ways to do the sampling depending on the tradeoff between the number of columns and running time, which we describe below. Proceeding iteratively, we write down Z_2' by setting its (i,j)-th row to the vectorization of $(A_1S_1)_i \otimes (A_3D_3)_j$. We then sample $d_2 = O(s_1 d_3/\epsilon)$ columns from A_2 and let D_2 denote that selection matrix. Finally, we define Z_1' by setting its (i,j)-th row to be the vectorization of $(A_2D_2)_i \otimes (A_3D_3)_j$. We obtain $C = A_1D_1$, $R = A_2D_2$ and $T = A_3D_3$. For the sampling steps, we can use a generalized matrix column subset selection technique, which extends a column subset selection technique of [BW14] in the context of CUR decompositions to the case when C is not necessarily a subset of the input. This gives $O(\mathrm{nnz}(A)\log n) + \widetilde{O}(n^2)\,\mathrm{poly}(k,1/\epsilon)$ time. Alternatively, we can use a technique we develop called tensor leverage score sampling described below, yielding $O(\mathrm{nnz}(A)) + n\,\mathrm{poly}(k,1/\epsilon)$ time.

A body of work in the matrix case has focused on finding the best possible number of columns and rows of a CUR decomposition, and we can ask the same question for tensors. It turns out that if one is given the factorization $\sum_{i=1}^k (U_B)_i \otimes (V_B)_i \otimes (W_B)_i$ of a rank-k tensor $B \in \mathbb{R}^{n\times n\times n}$ with $U_B, V_B, W_B \in \mathbb{R}^{n\times k}$, then one can find a set C of $O(k/\epsilon)$ columns,

a set R of $O(k/\epsilon)$ rows, and a set T of $O(k/\epsilon)$ tubes of A, together with a rank-k tensor U for which $\|U(C,R,T)-A\|_F^2 \leq (1+\epsilon)\|A-B\|_F^2$. This is based on an iterative argument, where the initial sampling (which needs to be our generalized matrix column subset selection rather than tensor leverage score sampling to achieve optimal bounds) is done with respect to $V_B^\top \odot W_B^\top$, and then an iterative argument is carried out. Since we show a matching lower bound on the number of columns, rows, tubes and rank of U, these parameters are tight. The algorithm is efficient if one is given a rank-k tensor B which is a $(1+O(\epsilon))$-approximation to A; if not then one can use Theorem 21.1.2 and and this step will be exponential time in k. If one just wants $O(k\log k + k/\epsilon)$ columns, rows, and tubes, then one can achieve $O(\text{nnz}(A)) + n\,\text{poly}(k,1/\epsilon)$ time, if one is given B.

Column-row, row-tube, tube-column face subset selection, and CURT decomposition. In tensor column-row, row-tube, tube-column face subset selection, the goal is to find three tensors: a subset $C \in \mathbb{R}^{c\times n\times n}$ of row-tube faces of A, a subset $R \in \mathbb{R}^{n\times r\times n}$ of tube-column faces of A, and a subset $T \in \mathbb{R}^{n\times n\times t}$ of column-row faces of A, such that there exists a tensor $U \in \mathbb{R}^{tn\times cn\times rn}$ with small rank for which $\|U(T_1,C_2,R_3)-A\|_F^2 \leq (1+\epsilon)\,\text{OPT}$, where $T_1 \in \mathbb{R}^{n\times tn}$ denotes the matrix obtained by flattening the tensor T along the first dimension, $C_2 \in \mathbb{R}^{n\times cn}$ denotes the matrix obtained by flattening the tensor C along the second dimension, and $R_3 \in \mathbb{R}^{n\times rn}$ denotes the matrix obtained by flattening the tensor T along the third dimension.

We solve this problem by first choosing two Gaussian matrices S_1 and S_2 with $s_1 = s_2 = O(k/\epsilon)$ columns, and then forming matrix $U_3 \in \mathbb{R}^{n\times s_1 s_2}$ with (i,j)-th column equal to $(A_1S_1)_i$, as well as matrix $V_3 \in \mathbb{R}^{n\times s_1 s_2}$ with (i,j)-th column equal to $(A_2S_2)_j$. Inspired by

the regression problem $\min_{W \in \mathbb{R}^{n \times s_1 s_2}} \|V_3 \cdot (W^\top \odot U_3^\top) - A_2\|_F$, we sample $d_3 = O(s_1 s_2/\epsilon)$ rows from A_2 and let $D_3 \in \mathbb{R}^{n \times n}$ denote this selection matrix. In other words, D_3 selects d_3 tube-column faces from the original tensor A. Thus, we obtain a small regression problem: $\min_W \|D_3 V_3 \cdot (W^\top \odot U_3^\top) - D_3 A_2\|_F$. By retensorizing the objective function, we obtain the problem $\min_W \|U_3 \otimes (D_3 V_3) \otimes W - A(I, D_3, I)\|_F$. Flattening the objective function along the third dimension, we obtain $\min_W \|W \cdot (U_3^\top \odot (D_3 V_3)^\top) - (A(I, D_3, I))_3\|_F$ which has optimal solution $(A(I, D_3, I))_3 (U_3^\top \odot (D_3 V_3)^\top)^\dagger$. Let W' denote $A(I, D_3, I))_3$. In the next step, we fix $W_2 = W'(U_3^\top \odot (D_3 V_3)^\top)^\dagger$ and $U_2 = U_3$, and consider the objective function $\min_V \|U_2 \cdot (V^\top \odot W_2^\top) - A_1\|_F$. Applying a similar argument, we obtain $V' = (A(D_2, I, I))_2$ and $U' = (A(I, I, D_1)_1)$. Let C denote $A(D_2, I, I)$, R denote $A(I, D_3, I)$, and T denote $A(I, I, D_1)$. Overall, this algorithm selects $\mathrm{poly}(k, 1/\epsilon)$ faces from each dimension.

Similar to our column-based CURT decomposition, our face-based CURT decomposition has the property that if one is given the factorization $\sum_{i=1}^k (U_B)_i \otimes (V_B)_i \otimes (W_B)_i$ of a rank-k tensor $B \in \mathbb{R}^{n \times n \times n}$ with $U_B, V_B, W_B \in \mathbb{R}^{n \times k}$ which is a $(1 + O(\epsilon))$-approximation to A, then one can find a set C of $O(k/\epsilon)$ row-tube faces, a set R of $O(k/\epsilon)$ tube-column faces, and a set T of $O(k/\epsilon)$ column-row faces of A, together with a rank-k tensor U for which $\|U(T_1, C_2, R_3) - A\|_F^2 \leq (1 + \epsilon)\,\mathrm{OPT}$.

Tensor multiple regression and tensor leverage score sampling. In the above we need to consider standard problems for matrices in the context of tensors. Suppose we are given a matrix $A \in \mathbb{R}^{n_1 \times n_2 n_3}$ and a matrix $B = (V^\top \odot W^\top) \in \mathbb{R}^{k \times n_2 n_3}$ with rows $(V_i \otimes W_i)$ for an $n_2 \times k$ matrix V and $n_3 \times k$ matrix W. Using TensorSketch [Pag13, PP13, ANW14] one can solve multiple regression $\min_U \|UB - A\|_F$ without forming B in $O(n_2 + n_3)\,\mathrm{poly}(k, 1/\epsilon)$

time, rather than the naïve $O(n_2 n_3)\,\mathrm{poly}(k, 1/\epsilon)$ time. However, this does not immediately help us if we would like to sample columns of such a matrix B proportional to its leverage scores. Even if we apply TensorSketch to compute a $k \times k$ change of basis matrix R in $O(n_2 + n_3)\,\mathrm{poly}(k, \log(n_2 n_3))$ time, for which the leverage scores of B are (up to a constant factor) the squared column norms of $R^{-1}B$, there are still $n_2 n_3$ leverage scores and we cannot write them all down! Nevertheless, we show we can still sample by them by using that the matrix of interest is formed via a tensor product, which can be rewritten as a matrix multiplication which we never need to explicily materialize. In more detail, for the i-th row $e_i R^{-1}$ of R^{-1}, we create a matrix V'^i by scaling each of the columns of $V^\top$ entrywise by the entries of z. The squared norms of $e_i R^{-1} B$ are exactly the squared entries of $(V'^i)W^\top$. We cannot compute this matrix product, but we can first sample a column of it proportional to its squared norm and then sample an entry in that column proportional to its square. To sample a column, we compute $G(V'^i)W^\top$ for a Gaussian matrix G with $O(\log n_3)$ rows by computing $G \cdot V'^i$, then computing $(G \cdot V'^i) \cdot W^\top$, which is $O(n_2 + n_3)\,\mathrm{poly}(k, \log(n_2 n_3))$ total time. After sampling a column, we compute the column exactly and sample a squared entry. We do this for each $i \in [k]$, first sampling an i proportional to $\|GV'^i W^\top\|_F^2$, then running the above scheme on that i. The $\mathrm{poly}(\log n)$ factor in the running time can be replaced by $\mathrm{poly}(k)$ if one wants to avoid a $\mathrm{poly}(\log n)$ dependence in the running time.

Entry-wise ℓ_1 low-rank approximation. We consider the problem of entrywise ℓ_1-low rank approximation of an $n \times n \times n$ tensor A, namely, the problem of finding a rank-k tensor B for which $\|A - B\|_1 \leq \mathrm{poly}(k, \log n)\,\mathrm{OPT}$, where $\mathrm{OPT} = \inf_{\text{rank-}k\ B} \|A - B\|_1$, and where for a tensor A, $\|A\|_1 = \sum_{i,j,k} |A_{i,j,k}|$. Our iterative existential argument can be applied in

much the same way as for the Frobenius norm. We iteratively flatten A along each of its three dimensions, obtaining A_1, A_2, and A_3 as above, and iteratively build a good rank-k solution B of the form $(A_1S_1X_1) \otimes (A_2S_2X_2) \otimes (A_3S_3X_3)$, where now the S_i are matrices of i.i.d. Cauchy random variables or sparse matrices of Cauchy random variables and the X_i are $O(k \log k) \times k$ matrices of indeterminates. For a matrix C and a matrix S of i.i.d. Cauchy random variables with k columns, it is known [SWZ17] that the column span of CS contains a $\text{poly}(k \log n)$-approximate rank-k space with respect to the entrywise ℓ_1-norm for C. In the case of tensors, we must perform an iterative flattening and retensorizing argument to guarantee there exists a tensor B of the form above. Also, if we insist on outputting a rank-k solution as opposed to a bicriteria solution, $\|(A_1S_1X_1) \otimes (A_2S_2X_2) \otimes (A_3S_3X_3) - A\|_1$ is not a polynomial of the X_i, and if we introduce sign variables for the n^3 absolute values, the running time of the polynomial solver will be $2^{\#\text{ of variables}} = 2^{\Omega(n^3)}$. We perform additional dimensionality reduction by Lewis weight sampling [CP15] from the flattenings to reduce the problem size to $\text{poly}(k)$. This small problem still has $\widetilde{O}(k^3)$ sign variables, and to obtain a $2^{\widetilde{O}(k^2)}$ running time we relax the reduced problem to a Frobenius norm problem, mildly increasing the approximation factor by another $\text{poly}(k)$ factor.

Combining the iterative existential argument with techniques in [SWZ17], we also obtain an ℓ_1 CURT decomposition algorithm (which is similar to the Frobenius norm result in Theorem 21.1.3), which can find $\widetilde{O}(k)$ columns, $\widetilde{O}(k)$ rows, $\widetilde{O}(k)$ tubes, and a tensor U. Our algorithm starts from a given factorization of a rank-k tensor $B = U_B \otimes V_B \otimes W_B$ found above. We compute a sampling and rescaling diagonal matrix D_1 according to the Lewis weights of matrix $B_1 = (V_B^\top \odot W_B^\top)$, where D_1 has $\widetilde{O}(k)$ nonzero entries. Then we iteratively construct B_2, D_2, B_3 and D_3. Finally we have $C = A_1D_1$ (selecting $\widetilde{O}(k)$ columns from

end procedure

A), $R = A_2D_2$ (selecting $\widetilde{O}(k)$ rows from A), $T = A_3D_3$ (selecting $\widetilde{O}(k)$ tubes from A) and tensor $U = ((B_1D_1)^\dagger) \otimes ((B_2D_2)^\dagger) \otimes ((B_3D_3)^\dagger)$.

Optimal matrix CUR decomposition. We also improve the $\mathrm{nnz}(A)\log n + (n+d)\,\mathrm{poly}(\log n, k, 1/\epsilon)$ running time of [BW14] for CUR decomposition of $A \in \mathbb{R}^{n\times d}$ to $\mathrm{nnz}(A) + (n+d)\,\mathrm{poly}(k, 1/\epsilon)$, while selecting the optimal number of columns, rows, and a rank-k matrix U. Using [CW13, MM13, NN13a], we find a matrix $\widehat{U}$ with k orthonormal columns in $\mathrm{nnz}(A) + n\,\mathrm{poly}(k/\epsilon)$ time for which $\min_V \|\widehat{U}V - A\|_F^2 \le (1+\epsilon)\|A - A_k\|_F^2$. Let $s_1 = \widetilde{O}(k/\epsilon^2)$ and $S_1 \in \mathbb{R}^{s_1\times n}$ be a sampling/rescaling matrix by the leverage scores of $\widehat{U}$. By strengthening the affine embedding analysis of [CW13] to leverage score sampling (the analysis of

[CW13] gives a weaker analysis for affine embeddings using leverage scores which does not allow approximation in the sketch space to translate to approximation in the original space), with probability at least 0.99, for all X' which satisfy $\|S_1\widehat{U}X' - S_1A\|_F^2 \leq (1+\epsilon')\min_X \|S_1\widehat{U}X - S_1A\|_F^2$, we have $\|\widehat{U}X' - A\|_F^2 \leq (1+\epsilon)\min_X \|\widehat{U}X - A\|_F^2$, where $\epsilon' = 0.0001\epsilon$. Applying our generalized row subset selection procedure, we can find Y, R for which $\|S_1\widehat{U}YR - S_1A\|_F^2 \leq (1+\epsilon')\min_X \|S_1\widehat{U}X - S_1A\|_F^2$, where R contains $O(k/\epsilon') = O(k/\epsilon)$ rescaled rows of S_1A. A key point is that rescaled rows of S_1A are also rescaled rows of A. Then, $\|\widehat{U}YR - A\|_F^2 \leq (1+\epsilon)\min_X \|\widehat{U}X - A\|_F^2$. Finding Y, R can be done in $d\,\mathrm{poly}(s_1/\epsilon) = d\,\mathrm{poly}(k/\epsilon)$ time. Now set $\widehat{V} = YR$. We can choose S_2 to be a sampling/rescaling matrix, and then find C, Z for which $\|CZ\widehat{V}S_2 - AS_2\|_F^2 \leq (1+\epsilon')\min_X \|X\widehat{V}S_2 - AS_2\|_F^2$ in a similar way, where C contains $O(k/\epsilon)$ rescaled columns of AS_2, and thus also of A. We thus have $\|CZYR - A\|_F^2 \leq (1+O(\epsilon))\|A - A_k\|_F^2$.

21.1.4 Comparison to [BCV14]

[BCV14] shows for a third order $n_1 \times n_2 \times n_3$ tensor A how to find a rank-k tensor B for which $\|A - B\|_F^2 \leq 5\,\mathrm{OPT}$ in $\mathrm{poly}(n_1 n_2 n_3)\exp(\mathrm{poly}(k))$ time. They generalize this to q-th order tensors to find a rank-k tensor B for which $\|A - B\|_F^2 = O(q)\,\mathrm{OPT}$ in $\mathrm{poly}(n_1 n_2 \cdots n_q)\exp(\mathrm{poly}(qk))$ time.

In contrast, we obtain a rank-k tensor B for which $\|A - B\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}$ in $\mathrm{nnz}(A) + n \cdot \mathrm{poly}(k/\epsilon) + \exp((k^2/\epsilon)\,\mathrm{poly}(q))$ time for every order q. Thus, we obtain a $(1+\epsilon)$ instead of an $O(q)$ approximation. The $O(q)$ approximation in [BCV14] seems inherent since the authors apply triangle inequality q times, each time losing a constant factor. This seems necessary since their argument is based on the span of the top k principal components in the SVD in each flattening separately containing a good space to project onto for a given mode. In contrast, our iterative existential argument chooses the space to project onto in successive modes *adaptively* as a function of spaces chosen for previous modes, and thus we obtain a $(1+\epsilon)^{O(q)} = (1 + O(\epsilon q))$-approximation, which becomes a $(1+\epsilon)$-approximation after replacing ϵ with ϵ/q. Also, importantly, our algorithm runs in $\mathrm{nnz}(A) + n \cdot \mathrm{poly}(k/\epsilon) + \exp((k^2/\epsilon)\,\mathrm{poly}(q))$ time and there are multiple hurdles we overcome to achieve this, as described in Section 21.1.2 above.

21.1.5 A Roadmap

Roadmap Section 21.2 introduces notation and definitions. Section 21.3 includes several tools. Our Frobenius norm low rank approximation algorithms are in Section 21.4. Section 21.5 extends our results to general q-th order tensors.

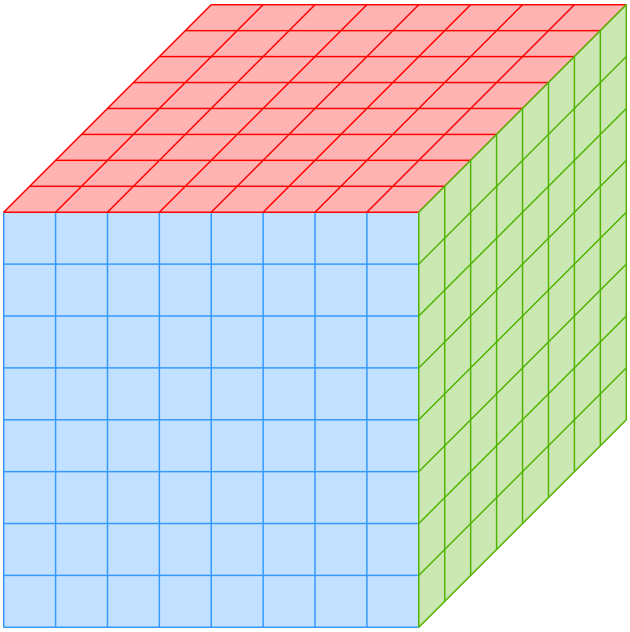

Figure 21.1: A 3rd order tensor with size $8 \times 8 \times 8$.

21.2 Notation

For an $n \in \mathbb{N}_+$, let $[n]$ denote the set $\{1, 2, \cdots, n\}$.

For any function f, we define $\widetilde{O}(f)$ to be $f \cdot \log^{O(1)}(f)$. In addition to $O(\cdot)$ notation, for two functions f, g, we use the shorthand $f \lesssim g$ (resp. $\gtrsim$) to indicate that $f \leq Cg$ (resp. $\geq$) for an absolute constant C. We use $f \eqsim g$ to mean $cf \leq g \leq Cf$ for constants c, C.

For a matrix A, we use $\|A\|_2$ to denote the spectral norm of A. For a tensor A, let $\|A\|$ and $\|A\|_2$ (which we sometimes use interchangeably) denote the spectral norm of tensor A,

$$\|A\| = \sup_{x,y,z \neq 0} \frac{|A(x, y, z)|}{\|x\| \cdot \|y\| \cdot \|z\|}.$$

Let $\|A\|_F$ denote the Frobenius norm of a matrix/tensor A, i.e., $\|A\|_F$ is the square root of

sum of squares of all the entries of A. For $1 \leq p < 2$, we use $\|A\|_p$ to denote the entry-wise ℓ_p-norm of a matrix/tensor A, i.e., $\|A\|_p$ is the p-th root of the sum of p-th powers of the absolute values of the entries of A. $\|A\|_1$ will be an important special case of $\|A\|_p$, which corresponds to the sum of absolute values of all of the entries.

Let $\text{nnz}(A)$ denote the number of nonzero entries of A. Let $\det(A)$ denote the determinant of a square matrix A. Let $A^\top$ denote the transpose of A. Let $A^\dagger$ denote the Moore-Penrose pseudoinverse of A. Let A^{-1} denote the inverse of a full rank square matrix.

For a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, its x-mode fibers are called column fibers ($x = 1$), row fibers ($x = 2$) and tube fibers ($x = 3$). For tensor A, we use $A_{*,j,l}$ to denote its (j,l)-th column, we use $A_{i,*,l}$ to denote its (i,l)-th row, and we use $A_{i,j,*}$ to denote its (i,j)-th tube.

A tensor A is symmetric if and only if for any i, j, k, $A_{i,j,k} = A_{i,k,j} = A_{j,i,k} = A_{j,k,i} = A_{k,i,j} = A_{k,j,i}$.

For a tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, we use $\top$ to denote rotation (3 dimensional transpose) so that $A^\top \in \mathbb{R}^{n_3 \times n_1 \times n_2}$. For a tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$ and matrix $B \in \mathbb{R}^{n_3 \times k}$, we define the tensor-matrix dot product to be $A \cdot B \in \mathbb{R}^{n_1 \times n_2 \times k}$.

We use $\otimes$ to denote outer product, $\circ$ to denote entrywise product, and $\cdot$ to denote dot product. Given two column vectors $u, v \in \mathbb{R}^n$, let $u \otimes v \in \mathbb{R}^{n \times n}$ and $(u \otimes v)_{i,j} = u_i \cdot v_j$, $u^\top v = \sum_{i=1}^n u_i v_i \in \mathbb{R}$ and $(u \circ v)_i = u_i v_i$.

Definition 21.2.1 ($\otimes$ product for vectors)**.** Given q vectors $u_1 \in \mathbb{R}^{n_1}$, $u_2 \in \mathbb{R}^{n_2}$, $\cdots$, $u_q \in \mathbb{R}^{n_q}$, we use $u_1 \otimes u_2 \otimes \cdots \otimes u_q$ to denote an $n_1 \times n_2 \times \cdots \times n_q$ tensor such that, for each $(j_1, j_2, \cdots, j_q) \in [n_1] \times [n_2] \times \cdots \times [n_q]$,

$$(u_1 \otimes u_2 \otimes \cdots \otimes u_q)_{j_1, j_2, \cdots, j_q} = (u_1)_{j_1} (u_2)_{j_2} \cdots (u_q)_{j_q},$$

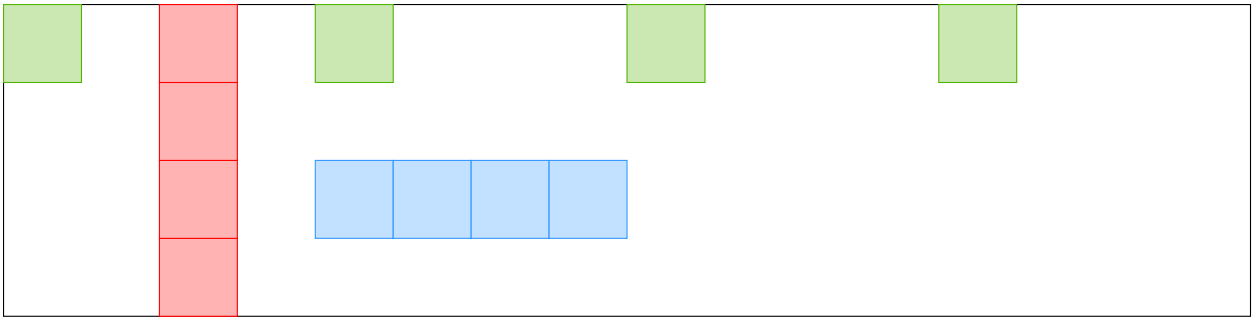

Figure 21.2: Flattening. We flatten a third order $4 \times 4 \times 4$ tensor along the 1st dimension to obtain a 4×16 matrix. The red blocks correspond to a column in the original third order tensor, the blue blocks correspond to a row in the original third order tensor, and the green blocks correspond to a tube in the original third order tensor.

where $(u_i)_{j_i}$ denotes the j_i-th entry of vector u_i.

Definition 21.2.2 (vec(), convert tensor into a vector)**.** Given a tensor $A \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_q}$, let $\text{vec}(A) \in \mathbb{R}^{1 \times \prod_{i=1}^{q} n_i}$ be a row vector, such that the *t-th* entry of $\text{vec}(A)$ is $A_{j_1, j_2, \cdots, j_q}$ where $t = (j_1 - 1) \prod_{i=2}^{q} n_i + (j_2 - 1) \prod_{i=3}^{q} n_i + \cdots + (j_{q-1} - 1) n_q + j_q$.

$$\text{For example if } u = \begin{bmatrix} 1 \\ 2 \end{bmatrix}, v = \begin{bmatrix} 3 \\ 4 \\ 5 \end{bmatrix} \text{ then } \text{vec}(u \otimes v) = \begin{bmatrix} 3 & 4 & 5 & 6 & 8 & 10 \end{bmatrix}.$$

Definition 21.2.3 ($\otimes$ product for matrices)**.** Given q matrices $U_1 \in \mathbb{R}^{n_1 \times k}$, $U_2 \in \mathbb{R}^{n_2 \times k}$, $\cdots$, $U_q \in \mathbb{R}^{n_q \times k}$, we use $U_1 \otimes U_2 \otimes \cdots \otimes U_q$ to denote an $n_1 \times n_2 \times \cdots \times n_q$ tensor which can be written as,

$$U_1 \otimes U_2 \otimes \cdots \otimes U_q = \sum_{i=1}^{k} (U_1)_i \otimes (U_2)_i \otimes \cdots \otimes (U_q)_i \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_q},$$

where $(U_j)_i$ denotes the i-th column of matrix $U_j \in \mathbb{R}^{n_j \times k}$.

Definition 21.2.4 ($\odot$ product for matrices)**.** Given q matrices $U_1 \in \mathbb{R}^{k \times n_1}$, $U_2 \in \mathbb{R}^{k \times n_2}$, $\cdots$, $U_q \in \mathbb{R}^{k \times n_q}$, we use $U_1 \odot U_2 \odot \cdots \odot U_q$ to denote a $k \times \prod_{j=1}^{q} n_j$ matrix where the i-th

row of $U_1 \odot U_2 \odot \cdots \odot U_q$ is the vectorization of $(U_1)^i \otimes (U_2)^i \otimes \cdots \otimes (U_q)^i$, i.e.,

$$U_1 \odot U_2 \odot \cdots \odot U_q = \begin{bmatrix} \mathrm{vec}((U_1)^1 \otimes (U_2)^1 \otimes \cdots \otimes (U_q)^1) \\ \mathrm{vec}((U_1)^2 \otimes (U_2)^2 \otimes \cdots \otimes (U_q)^2) \\ \cdots \\ \mathrm{vec}((U_1)^k \otimes (U_2)^k \otimes \cdots \otimes (U_q)^k) \end{bmatrix} \in \mathbb{R}^{k \times \prod_{j=1}^q n_j}.$$

where $(U_j)^i \in \mathbb{R}^{n_j}$ denotes the i-th row of matrix $U_j \in \mathbb{R}^{k \times n_j}$.

Definition 21.2.5 (Flattening vs unflattening/retensorizing)**.** Suppose we are given three matrices $U \in \mathbb{R}^{n_1 \times k}$, $V \in \mathbb{R}_{n_2 \times k}$, $W \in \mathbb{R}^{n_3 \times k}$. Let tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$ denote $U \otimes V \otimes W$. Let $A_1 \in \mathbb{R}^{n_1 \times n_2 n_3}$ denote a matrix obtained by flattening tensor A along the 1st dimension. Then $A_1 = U \cdot B$, where $B = V^\top \odot W^\top \in \mathbb{R}^{k \times n_2 n_3}$ denotes the matrix for which the i-th row is $\mathrm{vec}(V_i \otimes W_i), \forall i \in [k]$. We let the "flattening" be the operation that obtains A_1 by A. Given $A_1 = U \cdot B$, we can obtain tensor A by unflattening/retensorizing A_1. We let "retensorization" be the operation that obtains A from A_1. Similarly, let $A_2 \in \mathbb{R}^{n_2 \times n_1 n_3}$ denote a matrix obtained by flattening tensor A along the 2nd dimension, so $A_2 = V \cdot C$, where $C = W^\top \odot U^\top \in \mathbb{R}^{k \times n_1 n_3}$ denotes the matrix for which the i-th row is $\mathrm{vec}(W_i \otimes U_i), \forall i \in [k]$. Let $A_3 \in \mathbb{R}^{n_3 \times n_1 n_2}$ denote a matrix obtained by flattening tensor A along the 3rd dimension. Then, $A_3 = W \cdot D$, where $D = U^\top \odot V^\top \in \mathbb{R}^{k \times n_1 n_2}$ denotes the matrix for which the i-th row is $\mathrm{vec}(U_i \otimes V_i), \forall i \in [k]$.

Definition 21.2.6 ($(\cdot, \cdot, \cdot)$ operator for tensors and matrices)**.** Given tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$ and three matrices $B_1 \in \mathbb{R}^{n_1 \times d_1}$, $B_2 \in \mathbb{R}^{n_2 \times d_2}$, $B_3 \in \mathbb{R}^{n_3 \times d_3}$, we define tensors $A(B_1, I, I) \in \mathbb{R}^{d_1 \times n_2 \times n_3}$, $A(I, B_2, I) \in \mathbb{R}^{n_1 \times d_2 \times n_3}$, $A(I, I, B_3) \in \mathbb{R}^{n_1 \times n_2 \times d_3}$, $A(B_1, B_2, I) \in \mathbb{R}^{d_1 \times d_2 \times n_3}$,

$A(B_1, B_2, B_3) \in \mathbb{R}^{d_1 \times d_2 \times d_3}$ as follows,

$$\begin{aligned}
A(B_1, I, I)_{i,j,l} &= \sum_{i'=1}^{n_1} A_{i',j,l}(B_1)_{i',i}, && \forall (i,j,l) \in [d_1] \times [n_2] \times [n_3] \\
A(I, B_2, I)_{i,j,l} &= \sum_{j'=1}^{n_2} A_{i,j',l}(B_2)_{j',j}, && \forall (i,j,l) \in [n_1] \times [d_2] \times [n_3] \\
A(I, I, B_3)_{i,j,l} &= \sum_{l'=1}^{n_3} A_{i,j,l'}(B_3)_{l',l}, && \forall (i,j,l) \in [n_1] \times [n_2] \times [d_3] \\
A(B_1, B_2, I)_{i,j,l} &= \sum_{i'=1}^{n_1} \sum_{j'=1}^{n_2} A_{i',j',l}(B_1)_{i',i}(B_2)_{j',j}, && \forall (i,j,l) \in [d_1] \times [d_2] \times [n_3] \\
A(B_1, B_2, B_3)_{i,j,l} &= \sum_{i'=1}^{n_1} \sum_{j'=1}^{n_2} \sum_{l'=1}^{n_3} A_{i',j',l'}(B_1)_{i',i}(B_2)_{j',j}(B_3)_{l',l}, && \forall (i,j,l) \in [d_1] \times [d_2] \times [d_3]
\end{aligned}$$

Note that $B_1^\top A = A(B_1, I, I)$, $AB_3 = A(I, I, B_3)$ and $B_1^\top A B_3 = A(B_1, I, B_3)$. In our paper, if $\forall i \in [3], B_i$ is either a rectangular matrix or a symmetric matrix, then we sometimes use $A(B_1, B_2, B_3)$ to denote $A(B_1^\top, B_2^\top, B_3^\top)$ for simplicity. Similar to the $(\cdot, \cdot, \cdot)$ operator on 3rd order tensors, we can define the $(\cdot, \cdot, \cdots, \cdot)$ operator on higher order tensors.

For the matrix case, $\min_{\text{rank}-k\ A'} \|A - A'\|_F^2$ always exists. However, this is not true for tensors [DSL08]. For convenience, we redefine the notation of OPT and min.

Definition 21.2.7. Given tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}, k > 0$, if $\min_{\text{rank}-k\ A'} \|A - A'\|_F^2$ does not exist, then we define $\text{OPT} = \inf_{\text{rank}-k\ A'} \|A - A'\|_F^2 + \gamma$ for sufficiently small $\gamma > 0$, which can be an arbitrarily small positive function of n. We let $\min_{\text{rank}-k\ A'} \|A - A'\|_F^2$ be the value of OPT, and we let $\arg\min_{\text{rank}-k\ A'} \|A - A'\|_F^2$ be a rank $-k$ tensor $A_k \in \mathbb{R}^{n_1 \times n_2 \times n_3}$ which satisfies $\|A - A_k\|_F^2 = \text{OPT}$.

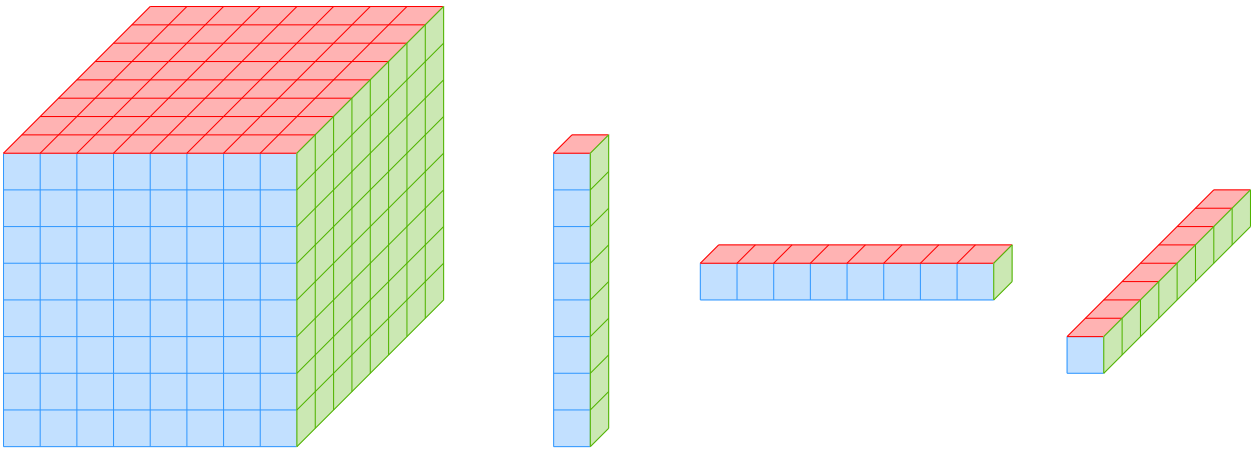

Figure 21.3: A 3rd order tensor contains n^2 columns, n^2 rows, and n^2 tubes.

21.3 Preliminaries

Section 21.3.1 provides the definitions for Subspace Embeddings and Approximate Matrix Product. We introduce the definition for Tensor-CURT decomposition in Section 21.3.2. Section 21.3.3 presents a tool which we call a "polynomial system verifier". Section 21.3.4 introduces a tool which is able to determine the minimum nonzero value of the absolute value of a polynomial evaluated on a set, provided the polynomial is never equal to 0 on that set. Section 21.3.5 shows how to relax an ℓ_p problem to an ℓ_2 problem. We provide definitions for CountSketch and Gaussian transforms in Section 21.3.6. We present Cauchy and p-stable transforms in Section 21.3.7. We introduce leverage scores and Lewis weights in Section 21.3.8 and Section 21.3.9. Finally, we explain an extension of CountSketch, which is called TensorSketch in Section 21.3.10.

21.3.1 Subspace Embeddings and Approximate Matrix Product

Definition 21.3.1 (Subspace Embedding)**.** A $(1 \pm \epsilon)$ ℓ_2-subspace embedding for the column space of an $n \times d$ matrix A is a matrix S for which for all $x \in \mathbb{R}^d$, $\|SAx\|_2^2 = (1 \pm \epsilon)\|Ax\|_2^2$.

Definition 21.3.2 (Approximate Matrix Product)**.** Let $0 < \epsilon < 1$ be a given approximation parameter. Given matrices A and B, where A and B each have n rows, the goal is to output a matrix C so that $\|A^\top B - C\|_F \leq \epsilon \|A\|_F \|B\|_F$. Typically C has the form $A^\top S^\top SB$, for a random matrix S with a small number of rows. See, e.g., Lemma 32 of [CW13] for a number of example matrices S with $O(\epsilon^{-2})$ rows for which this property holds.

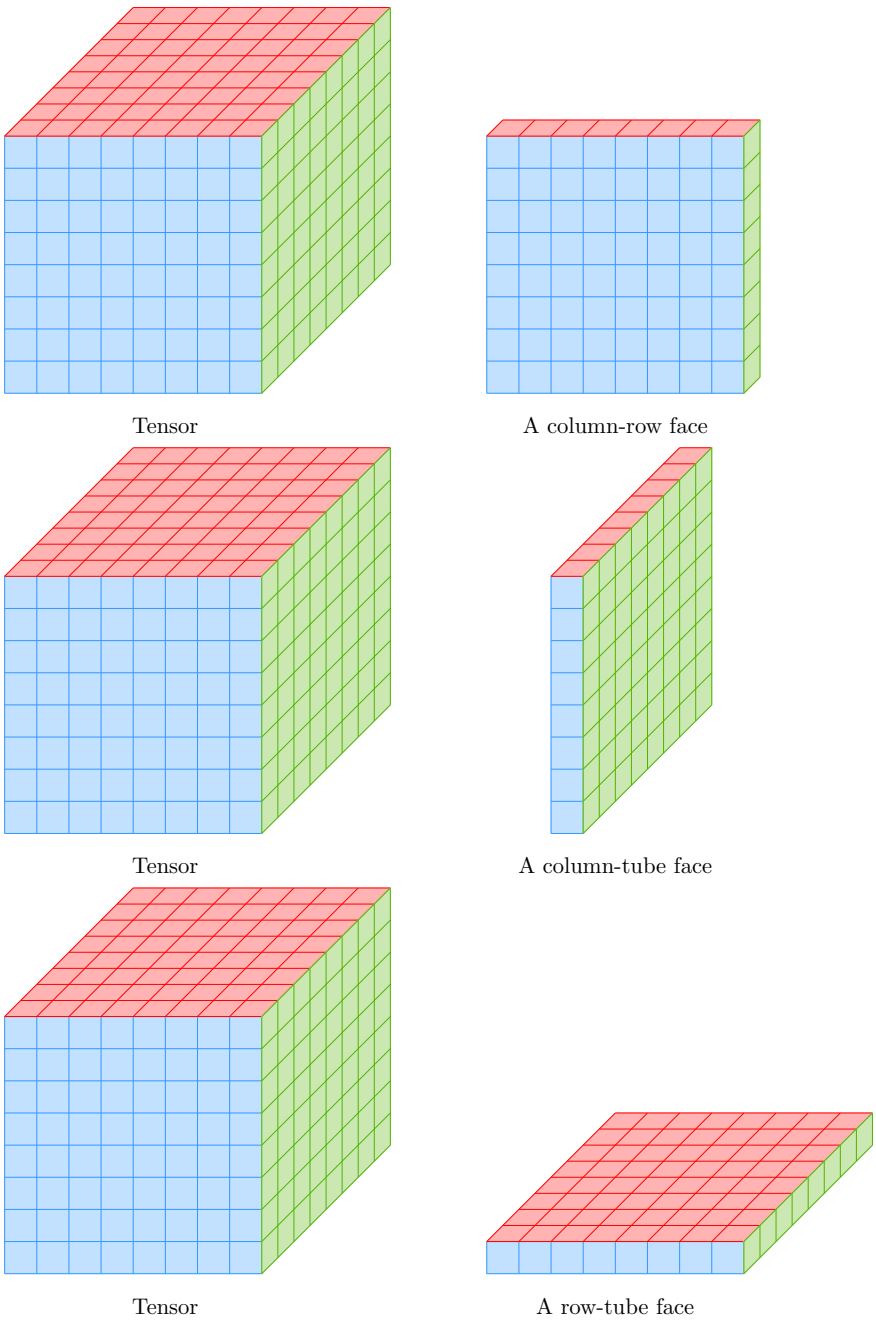

Figure 21.4: A third order tensor has three types of faces: the column-row faces, the column-tube faces, and the row-tube faces

21.3.2 Tensor CURT decomposition

We first review matrix CUR decompositions:

Definition 21.3.3 (Matrix CUR, exact)**.** Given a matrix $A \in \mathbb{R}^{n \times d}$, we choose $C \in \mathbb{R}^{n \times c}$ to be a subset of columns of A and $R \in \mathbb{R}^{r \times n}$ to be a subset of rows of A. If there exists a matrix $U \in \mathbb{R}^{c \times r}$ such that A can be written as,

$$CUR = A,$$

then we say C, U, R is matrix A's CUR decomposition.

Definition 21.3.4 (Matrix CUR, approximate)**.** Given a matrix $A \in \mathbb{R}^{n \times d}$, a parameter $k \geq 1$, an approximation ratio $\alpha > 1$, and a norm $\|\|\|_\xi$, we choose $C \in \mathbb{R}^{n \times c}$ to be a subset of columns of A and $R \in \mathbb{R}^{r \times n}$ to be a subset of rows of A. Then if there exists a matrix $U \in \mathbb{R}^{c \times r}$ such that,

$$\|CUR - A\|_\xi \leq \alpha \min_{\text{rank}-k \ A_k} \|A_k - A\|_\xi,$$

where $\|\|\|_\xi$ can be operator norm, Frobenius norm or Entry-wise ℓ_1 norm, we say that C, U, R is matrix A's approximate CUR decomposition, and sometimes just refer to this as a CUR decomposition.

Definition 21.3.5 ([Bou11])**.** Given matrix $A \in \mathbb{R}^{m \times n}$, integer k, and matrix $C \in \mathbb{R}^{m \times r}$ with $r > k$, we define the matrix $\Pi^\xi_{C,k}(A) \in \mathbb{R}^{m \times n}$ to be the best approximation to A (under the ξ-norm) within the column space of C of rank at most k; so, $\Pi^\xi_{C,k}(A) \in \mathbb{R}^{m \times n}$ minimizes the residual $\|A - \widehat{A}\|_\xi$, over all $\widehat{A} \in \mathbb{R}^{m \times n}$ in the column space of C of rank at most k.

We define the following notion of tensor-CURT decomposition.

Definition 21.3.6 (Tensor CURT, exact)**.** Given a tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, we choose three sets of pair of coordinates $S_1 \subseteq [n_2] \times [n_3], S_2 \subseteq [n_1] \times [n_3], S_3 \subseteq [n_1] \times [n_2]$. We define $c = |S_1|$, $r = |S_2|$ and $t = |S_3|$. Let $C \in \mathbb{R}^{n_1 \times c}$ denote a subset of columns of A, $R \in \mathbb{R}^{n_2 \times r}$ denote a subset of rows of A, and $T \in \mathbb{R}^{n_3 \times t}$ denote a subset of tubes of A. If there exists a tensor $U \in \mathbb{R}^{c \times r \times t}$ such that A can be written as

$$(((U \cdot T^\top)^\top \cdot R^\top)^\top \cdot C^\top)^\top = A,$$

or equivalently,

$$U(C, R, T) = A,$$

or equivalently,

$$\forall (i,j,l) \in [n_1] \times [n_2] \times [n_3], A_{i,j,l} = \sum_{u_1=1}^{c} \sum_{u_2=1}^{r} \sum_{u_3=1}^{t} U_{u_1,u_2,u_3} C_{i,u_1} R_{j,u_2} T_{l,u_3},$$

then we say C, U, R, T is tensor A's CURT decomposition.

Definition 21.3.7 (Tensor CURT, approximate)**.** Given a tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, for some $k \geq 1$, for some approximation $\alpha > 1$, for some norm $\|\|_\xi$, we choose three sets of pair of coordinates $S_1 \subseteq [n_2] \times [n_3], S_2 \subseteq [n_1] \times [n_3], S_3 \subseteq [n_1] \times [n_2]$. We define $c = |S_1|$, $r = |S_2|$ and $t = |S_3|$. Let $C \in \mathbb{R}^{n_1 \times c}$ denote a subset of columns of A, $R \in \mathbb{R}^{n_2 \times r}$ denote a subset of rows of A, and $T \in \mathbb{R}^{n_3 \times t}$ denote a subset of tubes of A. If there exists a tensor $U \in \mathbb{R}^{c \times r \times t}$ such that

$$\|U(C, R, T) - A\|_\xi \leq \alpha \min_{\text{rank}-k \ A_k} \|A_k - A\|_\xi,$$

where $\|\|_\xi$ is operator norm, Frobenius norm or Entry-wise ℓ_1 norm, then we refer to C, U, R, T as an approximate CUR decomposition of A, and sometimes just refer to this as a CURT decomposition of A.

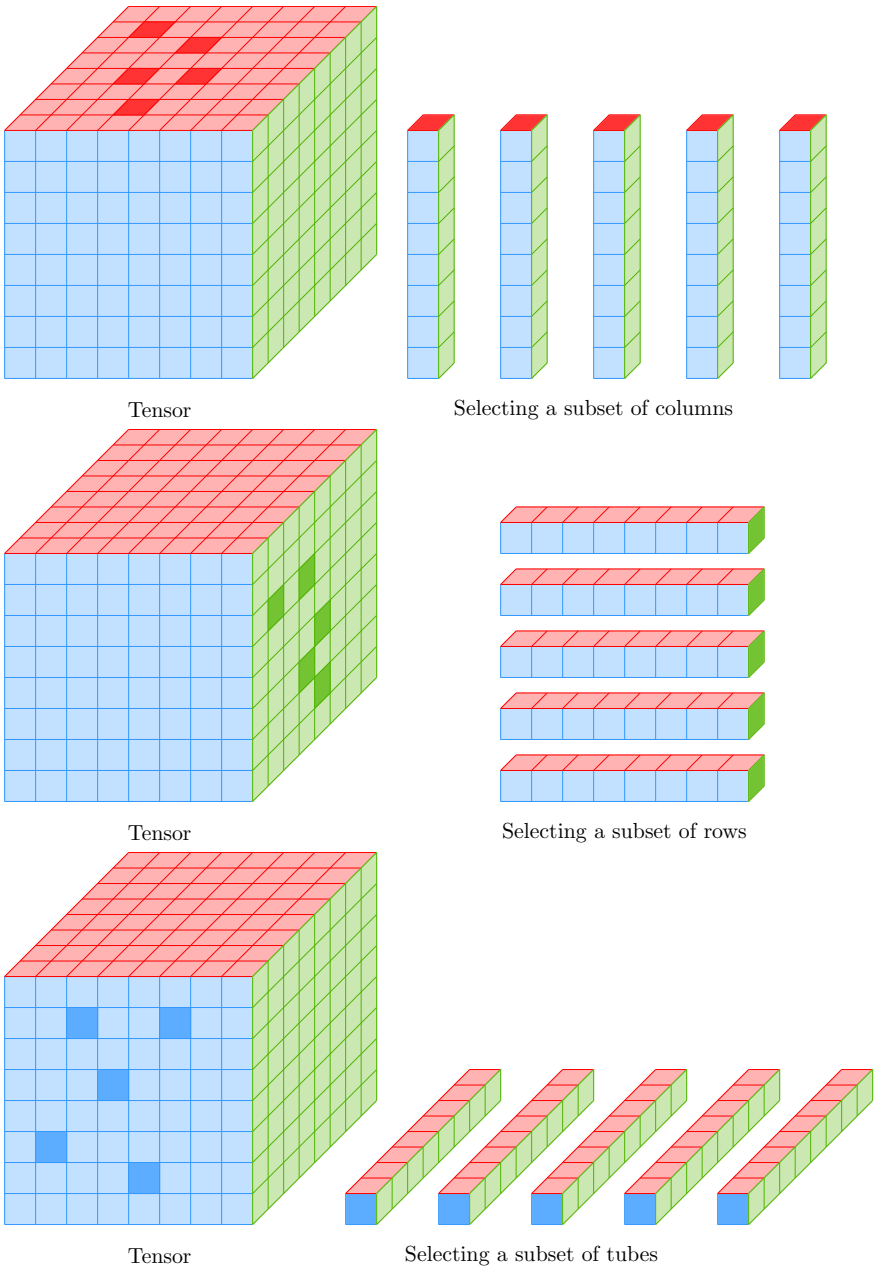

Figure 21.5: Column subset selection, row subset selection and tube subset selection.

Recently, [TM17] studied a very different face-based tensor-CUR decomposition, which selects faces from tensors rather than columns. To achieve their results, [TM17] need to make several incoherence assumptions on the original tensor. Their sample complexity depends on $\log n$, and they only sample two of the three dimensions. We will provide more general face-based tensor CURT decompositions.

Definition 21.3.8 (Tensor (face-based) CURT, exact)**.** Given a tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, we choose three sets of coordinates $S_1 \subseteq [n_1], S_2 \subseteq [n_2], S_3 \subseteq [n_3]$. We define $c = |S_1|$, $r = |S_2|$ and $t = |S_3|$. Let $C \in \mathbb{R}^{c \times n_2 \times n_3}$ denote a subset of row-tube faces of A, $R \in \mathbb{R}^{n_1 \times r \times n_3}$ denote a subset of column-tube faces of A, and $T \in \mathbb{R}^{n_1 \times n_2 \times t}$ denote a subset of column-row faces of A. Let $C_2 \in \mathbb{R}^{n_2 \times cn_3}$ denote the matrix obtained by flattening the tensor C along the second dimension. Let $R_3 \in \mathbb{R}^{n_3 \times rn_1}$ denote the matrix obtained by flattening the tensor R along the third dimension. Let $T_1 \in \mathbb{R}^{n_1 \times tn_2}$ denote the matrix obtained by flattening the tensor T along the first dimension. If there exists a tensor $U \in \mathbb{R}^{tn_2 \times cn_3 \times rn_1}$ such that A can be written as

$$\sum_{i=1}^{tn_2} \sum_{j=1}^{cn_3} \sum_{l=1}^{rn_1} U_{i,j,l} (T_1)_l \otimes (C_2)_i \otimes (R_3)_j = A,$$

$$U(T_1, C_2, R_3) = A,$$

or equivalently,

$$\forall (i', j', l') \in [n_1] \times [n_2] \times [n_3], A_{i,j,l} = \sum_{i=1}^{tn_1} \sum_{j=1}^{cn_3} \sum_{l=1}^{rn_2} U_{i,j,l} (T_1)_{i',i} (C_2)_{j',j} (R_3)_{l',l},$$

then we say C, U, R, T is tensor A's (face-based) CURT decomposition.

Definition 21.3.9 (Tensor (face-based) CURT, approximate)**.** Given a tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, for some $k \geq 1$, for some approximation $\alpha > 1$, for some norm $\|\|\|_\xi$,we choose three sets of coordinates $S_1 \subseteq [n_1], S_2 \subseteq [n_2], S_3 \subseteq [n_3]$. We define $c = |S_1|$, $r = |S_2|$ and $t = |S_3|$. Let $C \in \mathbb{R}^{c \times n_2 \times n_3}$ denote a subset of row-tube faces of A, $R \in \mathbb{R}^{n_1 \times r \times n_3}$ denote a subset of column-tube faces of A, and $T \in \mathbb{R}^{n_1 \times n_2 \times t}$ denote a subset of column-row faces of A. Let $C_2 \in \mathbb{R}^{n_2 \times cn_3}$ denote the matrix obtained by flattening the tensor C along the second dimension. Let $R_3 \in \mathbb{R}^{n_3 \times rn_1}$ denote the matrix obtained by flattening the tensor R along the third dimension. Let $T_1 \in \mathbb{R}^{n_1 \times tn_2}$ denote the matrix obtained by flattening the tensor T along the first dimension. If there exists a tensor $U \in \mathbb{R}^{tn_2 \times cn_3 \times rn_1}$ such that

$$\|U(T_1, C_2, R_3) - A\|_\xi \leq \alpha \min_{\text{rank}-k \ A_k} \|A_k - A\|_\xi,$$

where $\|\|\|_\xi$ is operator norm, Frobenius norm or Entry-wise ℓ_1 norm, then we refer to C, U, R, T as an approximate CUR decomposition of A, and sometimes just refer to this as a (face-based) CURT decomposition of A.

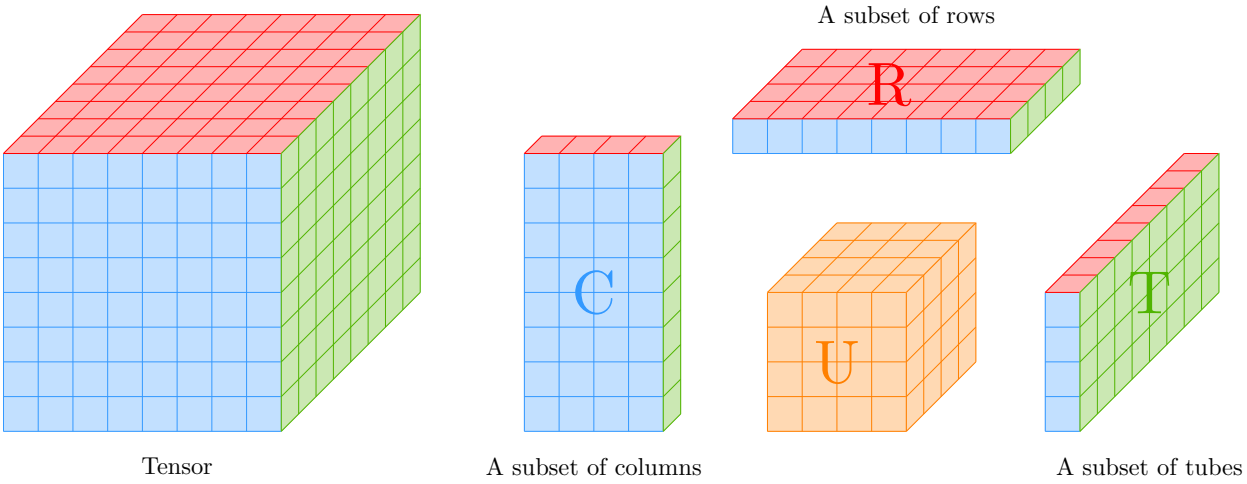

Figure 21.6: An example tensor CURT decomposition.

21.3.3 Polynomial system verifier

We use the polynomial system verifiers independently developed by Renegar [Ren92a, Ren92b] and Basu *et al.* [BPR96].

Theorem 21.3.1 (Decision Problem [Ren92a, Ren92b, BPR96])**.** *Given a real polynomial system $P(x_1, x_2, \cdots, x_v)$ having v variables and m polynomial constraints $f_i(x_1, x_2, \cdots, x_v)\Delta_i 0, \forall i \in [m]$, where Δ_i is any of the "standard relations": $\{>, \geq, =, \neq, \leq, <\}$, let d denote the maximum degree of all the polynomial constraints and let H denote the maximum bitsize of the coefficients of all the polynomial constraints. Then in*

$$(md)^{O(v)} \operatorname{poly}(H),$$

time one can determine if there exists a solution to the polynomial system P.

Recently, this technique has been used to solve a number of low-rank approximation and matrix factorization problems [AGKM12, Mad13, CW15a, BDL16, RSW16, SWZ17].

21.3.4 Lower bound on the cost of a polynomial system

An important result we use is the following lower bound on the minimum value attained by a polynomial restricted to a compact connected component of a basic closed semi-algebraic subset of $\mathbb{R}^v$.

Theorem 21.3.2 ([JPT13]). *Let* $T = \{x \in \mathbb{R}^v | f_1(x) \geq 0, \cdots, f_\ell(x) \geq 0, f_{\ell+1}(x) = 0, \cdots, f_m(x) = 0\}$ *be defined by polynomials* $f_1, \cdots, f_m \in \mathbb{Z}[x_1, \cdots, x_v]$ *with* $n \geq 2$*, degrees bounded by an even integer* d*, and coefficients of absolute value at most* H*, and let* C *be a compact connected (in the topological sense) component of* T*. Let* $g \in \mathbb{Z}[x_1, \cdots, x_v]$ *be a polynomial of degree at most* d *and coefficients of absolute value bounded by* H*. Then, the minimum value that* g *takes over* C *satisfies that if it is not zero, then its absolute value is greater than or equal to*

$$(2^{4-v/2}\widetilde{H}d^v)^{-v2^v d^v},$$

where $\widetilde{H} = \max\{H, 2v + 2m\}$.

While the above theorem involves notions from topology, we shall apply it in an elementary way. Namely, in our setting T will be bounded and so every connected component, which is by definition closed, will also be bounded and therefore compact. As the connected components partition T the theorem will just be applied to give a global minimum value of g on T provided that it is non-zero.

21.3.5 Frobenius norm and ℓ_2 relaxation

Theorem 21.3.3 (Generalized rank-constrained matrix approximations, Theorem 2 in [FT07])**.** *Given matrices $A \in \mathbb{R}^{n\times d}$, $B \in \mathbb{R}^{n\times p}$, and $C \in \mathbb{R}^{q\times d}$, let the SVD of B be $B = U_B \Sigma_B V_B^\top$ and the SVD of C be $C = U_C \Sigma_C V_C^\top$. Then,*

$$B^\dagger (U_B U_B^\top A V_C C_C^\top)_k C^\dagger = \underset{\text{rank}-k \;\; X\in\mathbb{R}^{p\times q}}{\arg\min} \|A - BXC\|_F,$$

where $(U_B U_B^\top A V_C V_C^\top)_k \in \mathbb{R}^{p\times q}$ is of rank at most k and denotes the best rank-k approximation to $U_B U_B^\top A V_C V_C^\top \in \mathbb{R}^{p\times d}$ in Frobenius norm.

Claim 21.3.4 (ℓ_2 relaxation of ℓ_p-regression)**.** *Let $p \in [1, 2)$. For any $A \in \mathbb{R}^{n\times d}$ and $b \in \mathbb{R}^n$, define $x^* = \underset{x\in\mathbb{R}^d}{\arg\min} \|Ax - b\|_p$ and $x' = \underset{x\in\mathbb{R}^d}{\arg\min} \|Ax - b\|_2$. Then,*

$$\|Ax^* - b\|_p \le \|Ax' - b\|_p \le n^{1/p-1/2} \cdot \|Ax^* - b\|_p.$$

Claim 21.3.5 ((Matrix) Frobenius norm relaxation of ℓ_p-low rank approximation)**.** *Let $p \in [1, 2)$ and for any matrix $A \in \mathbb{R}^{n\times d}$, define $A^* = \underset{\text{rank}-k \;\; B\in\mathbb{R}^{n\times d}}{\arg\min} \|B - A\|_p$ and $A' = \underset{\text{rank}-k \;\; B\in\mathbb{R}^{n\times d}}{\arg\min} \|B - A\|_F$. Then*

$$\|A^* - A\|_p \le \|A' - A\|_p \le (nd)^{1/p-1/2} \|A^* - A\|_p.$$

Claim 21.3.6 ((Tensor) Frobenius norm relaxation of ℓ_p-low rank approximation)**.** *Let $p \in [1, 2)$ and for any matrix $A \in \mathbb{R}^{n_1\times n_2\times n_3}$, define*

$$A^* = \underset{\text{rank}-k \;\; B\in\mathbb{R}^{n_1\times n_2\times n_3}}{\arg\min} \|B - A\|_p$$

and

$$A' = \underset{\text{rank}-k \;\; B\in\mathbb{R}^{n_1\times n_2\times n_3}}{\arg\min} \|B - A\|_F.$$

Then

$$\|A^* - A\|_p \leq \|A' - A\|_p \leq (n_1 n_2 n_3)^{1/p-1/2} \|A^* - A\|_p.$$

21.3.6 CountSketch and Gaussian transforms

Definition 21.3.10 (Sparse embedding matrix or CountSketch transform)**.** A CountSketch transform is defined to be $\Pi = \sigma \cdot \Phi D \in \mathbb{R}^{m \times n}$. Here, σ is a scalar, D is an $n \times n$ random diagonal matrix with each diagonal entry independently chosen to be $+1$ or -1 with equal probability, and $\Phi \in \{0,1\}^{m \times n}$ is an $m \times n$ binary matrix with $\Phi_{h(i),i} = 1$ and all remaining entries 0, where $h : [n] \to [m]$ is a random map such that for each $i \in [n]$, $h(i) = j$ with probability $1/m$ for each $j \in [m]$. For any matrix $A \in \mathbb{R}^{n \times d}$, ΠA can be computed in $O(\text{nnz}(A))$ time. For any tensor $A \in \mathbb{R}^{n \times d_1 \times d_2}$, ΠA can be computed in $O(\text{nnz}(A))$ time. Let Π_1, Π_2, Π_3 denote three CountSktech transforms. For any tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, $A(\Pi_1, \Pi_2, \Pi_3)$ can be computed in $O(\text{nnz}(A))$ time.

If the above scalar σ is not specified in the context, we assume the scalar σ to be 1.

Definition 21.3.11 (Gaussian matrix or Gaussian transform)**.** Let $S = \sigma \cdot G \in \mathbb{R}^{m \times n}$ where σ is a scalar, and each entry of $G \in \mathbb{R}^{m \times n}$ is chosen independently from the standard Gaussian distribution. For any matrix $A \in \mathbb{R}^{n \times d}$, SA can be computed in $O(m \cdot \text{nnz}(A))$ time. For any tensor $A \in \mathbb{R}^{n \times d_1 \times d_2}$, SA can be computed in $O(m \cdot \text{nnz}(A))$ time.

If the above scalar σ is not specified in the context, we assume the scalar σ to be $1/\sqrt{m}$. In most places, we can combine CountSketch and Gaussian transforms to achieve the following:

Definition 21.3.12 (CountSketch + Gaussian transform)**.** Let $S' = S\Pi$, where $\Pi \in \mathbb{R}^{t \times n}$ is the CountSketch transform (defined in Definition 21.3.10) and $S \in \mathbb{R}^{m \times t}$ is the Gaussian transform (defined in Definition 21.3.11). For any matrix $A \in \mathbb{R}^{n \times d}$, $S'A$ can be computed in $O(\text{nnz}(A) + dtm^{\omega-2})$ time, where ω is the matrix multiplication exponent.

Lemma 21.3.7 (Affine Embedding - Theorem 39 in [CW13]). *Given matrices $A \in \mathbb{R}^{n\times r}, B \in \mathbb{R}^{n\times d}$, and $\mathrm{rank}(A) = k$, let $m = \mathrm{poly}(k/\epsilon)$, $S \in \mathbb{R}^{m\times n}$ be a sparse embedding matrix (Definition 21.3.10) with scalar $\sigma = 1$. Then with probability at least 0.999, $\forall X \in \mathbb{R}^{r\times d}$, we have*

$$(1-\epsilon)\cdot\|AX-B\|_F^2 \leq \|S(AX-B)\|_F^2 \leq (1+\epsilon)\|AX-B\|_F^2.$$

Lemma 21.3.8 (see, e.g., Lemma 10 in version 1 of [BWZ16][8]). *Let $m = \Omega(k/\epsilon)$, $S = \frac{1}{\sqrt{m}}\cdot G$, where $G \in \mathbb{R}^{m\times n}$ is a random matrix where each entry is an i.i.d Gaussian $N(0,1)$. Then with probability at least 0.998, S satisfies $(1\pm 1/8)$ Subspace Embedding (Definition 21.3.1) for any fixed matrix $C \in \mathbb{R}^{n\times k}$, and it also satisfies $O(\sqrt{\epsilon/k})$ Approximate Matrix Product (Definition 21.3.2) for any fixed matrix A and B which has the same number of rows.*

Lemma 21.3.9 (see, e.g., Lemma 11 in version 1 of [BWZ16]). *Let $m = \Omega(k^2 + k/\epsilon)$, $\Pi \in \mathbb{R}^{m\times n}$, where Π is a sparse embedding matrix (Definition 21.3.10) with scalar $\sigma = 1$, then with probability at least 0.998, S satisfies $(1\pm 1/8)$ Subspace Embedding (Definition 21.3.1) for any fixed matrix $C \in \mathbb{R}^{n\times k}$, and it also satisfies $O(\sqrt{\epsilon/k})$ Approximate Matrix Product (Definition 21.3.2) for any fixed matrix A and B which has the same number of rows.*

Lemma 21.3.10 (see, e.g., Lemma 12 in version 1 of [BWZ16]). *Let $m_2 = \Omega(k^2 + k/\epsilon)$, $\Pi \in \mathbb{R}^{m_2\times n}$, where Π is a sparse embedding matrix (Definition 21.3.10) with scalar $\sigma = 1$. Let $m_1 = \Omega(k/\epsilon)$, $S = \frac{1}{\sqrt{m_1}}\cdot G$, where $G \in \mathbb{R}^{m_1\times m_2}$ is a random matrix where each entry is an i.i.d Gaussian $N(0,1)$. Let $S' = S\Pi$. Then with probability at least 0.99, S' is a $(1\pm 1/3)$ Subspace Embedding (Definition 21.3.1) for any fixed matrix $C \in \mathbb{R}^{n\times k}$, and it also satisfies*

[8] https://arxiv.org/pdf/1504.06729v1.pdf

$O(\sqrt{\epsilon/k})$ *Approximate Matrix Product (Definition 21.3.2) for any fixed matrix A and B which have the same number of rows.*

Theorem 21.3.11 (Theorem 36 in [CW13])**.** *Given $A \in \mathbb{R}^{n\times k}, B \in \mathbb{R}^{n\times d}$, suppose $S \in \mathbb{R}^{m\times n}$ is such that S is a $(1 \pm \frac{1}{\sqrt{2}})$ Subspace Embedding for A, and satisfies $O(\sqrt{\epsilon/k})$ Approximate Matrix Product for matrices A and C where C with n rows, where C depends on A and B. If*

$$\widehat{X} = \arg\min_{X\in\mathbb{R}^{k\times d}} \|SAX - SB\|_F^2,$$

then

$$\|A\widehat{X} - B\|_F^2 \leq (1+\epsilon)\min_{X\in\mathbb{R}^{k\times d}} \|AX - B\|_F^2.$$

21.3.7 Cauchy and p-stable transforms

Definition 21.3.13 (Dense Cauchy transform)**.** Let $S = \sigma \cdot C \in \mathbb{R}^{m \times n}$ where σ is a scalar, and each entry of $C \in \mathbb{R}^{m \times n}$ is chosen independently from the standard Cauchy distribution. For any matrix $A \in \mathbb{R}^{n \times d}$, SA can be computed in $O(m \cdot \text{nnz}(A))$ time.

Definition 21.3.14 (Sparse Cauchy transform)**.** Let $\Pi = \sigma \cdot SC \in \mathbb{R}^{m \times n}$, where σ is a scalar, $S \in \mathbb{R}^{m \times n}$ has each column chosen independently and uniformly from the m standard basis vectors of $\mathbb{R}^m$, and $C \in \mathbb{R}^{n \times n}$ is a diagonal matrix with diagonals chosen independently from the standard Cauchy distribution. For any matrix $A \in \mathbb{R}^{n \times d}$, ΠA can be computed in $O(\text{nnz}(A))$ time. For any tensor $A \in \mathbb{R}^{n \times d_1 \times d_2}$, ΠA can be computed in $O(\text{nnz}(A))$ time. Let $\Pi_1 \in \mathbb{R}^{m_1 \times n_1}, \Pi_2 \in \mathbb{R}^{m_2 \times n_2}, \Pi_3 \in \mathbb{R}^{m_3 \times n_3}$ denote three sparse Cauchy transforms. For any tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, $A(\Pi_1, \Pi_2, \Pi_3) \in \mathbb{R}^{m_1 \times m_2 \times m_3}$ can be computed in $O(\text{nnz}(A))$ time.

Definition 21.3.15 (Dense p-stable transform)**.** Let $p \in (1, 2)$. Let $S = \sigma \cdot C \in \mathbb{R}^{m \times n}$, where σ is a scalar, and each entry of $C \in \mathbb{R}^{m \times n}$ is chosen independently from the standard p-stable distribution. For any matrix $A \in \mathbb{R}^{n \times d}$, SA can be computed in $O(m \, \text{nnz}(A))$ time.

Definition 21.3.16 (Sparse p-stable transform)**.** Let $p \in (1, 2)$. Let $\Pi = \sigma \cdot SC \in \mathbb{R}^{m \times n}$, where σ is a scalar, $S \in \mathbb{R}^{m \times n}$ has each column chosen independently and uniformly from the m standard basis vectors of $\mathbb{R}^m$, and $C \in \mathbb{R}^{n \times n}$ is a diagonal matrix with diagonals chosen independently from the standard p-stable distribution. For any matrix $A \in \mathbb{R}^{n \times d}$, ΠA can be computed in $O(\text{nnz}(A))$ time. For any tensor $A \in \mathbb{R}^{n \times d_1 \times d_2}$, ΠA can be computed in $O(\text{nnz}(A))$ time. Let $\Pi_1 \in \mathbb{R}^{m_1 \times n_1}, \Pi_2 \in \mathbb{R}^{m_2 \times n_2}, \Pi_3 \in \mathbb{R}^{m_3 \times n_3}$ denote three sparse p-stable transforms. For any tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, $A(\Pi_1, \Pi_2, \Pi_3) \in \mathbb{R}^{m_1 \times m_2 \times m_3}$ can be computed in $O(\text{nnz}(A))$ time.

21.3.8 Leverage scores

Definition 21.3.17 (Leverage scores)**.** Let $U \in \mathbb{R}^{n \times k}$ have orthonormal columns, and let $p_i = u_i^2/k$, where $u_i^2 = \|e_i^\top U\|_2^2$ is the i-th leverage score of U.

Definition 21.3.18 (Leverage score sampling)**.** Given $A \in \mathbb{R}^{n \times d}$ with rank k, let $U \in \mathbb{R}^{n \times k}$ be an orthonormal basis of the column space of A, and for each i let p_i be the squared row norm of the i-th row of U, i.e., the i-th leverage score. Let $k \cdot p_i$ denote the i-th leverage score of U scaled by k. Let $\beta > 0$ be a constant and $q = (q_1, \cdots, q_n)$ denote a distribution such that, for each $i \in [n]$, $q_i \geq \beta p_i$. Let s be a parameter. Construct an $n \times s$ sampling matrix B and an $s \times s$ rescaling matrix D as follows. Initially, $B = 0^{n \times s}$ and $D = 0^{s \times s}$. For each column j of B, D, independently, and with replacement, pick a row index $i \in [n]$ with probability q_i, and set $B_{i,j} = 1$ and $D_{j,j} = 1/\sqrt{q_i s}$. We denote this procedure LEVERAGE SCORE SAMPLING according to the matrix A.

21.3.9 Lewis weights

We follow the exposition of Lewis weights from [CP15].

Definition 21.3.19. For a matrix A, let a_i denote the i^{th} row of A, where $a_i (= (A^i)^\top)$ is a column vector. The statistical leverage score of a row a_i is

$$\tau_i(A) \stackrel{\text{def}}{=} a_i^\top (A^\top A)^{-1} a_i = \|(A^\top A)^{-1/2} a_i\|_2^2.$$

For a matrix A and norm p, the ℓ_p Lewis weights w are the unique weights such that for each row i we have

$$w_i = \tau_i(W^{1/2-1/p} A).$$

or equivalently,

$$a_i^\top (A^\top W^{1-2/p} A)^{-1} a_i = w_i^{2/p}.$$

Lemma 21.3.12 (Lemma 2.4 of [CP15] and Lemma 7 of [CLM+15])**.** *Given a matrix $A \in \mathbb{R}^{n \times d}$, $n \geq d$, for any constant $C > 0, 4 > p \geq 1$, there is an algorithm which can compute C-approximate ℓ_p Lewis weights for every row i of A in $O((nnz(A) + d^\omega \log d) \log n)$ time, where $\omega < 2.373$ is the matrix multiplication exponent[Str69, CW87, Wil12].*

Lemma 21.3.13 (Theorem 7.1 of [CP15])**.** *Given matrix $A \in \mathbb{R}^{n \times d}$ ($n \geq d$) with ℓ_p ($4 > p \geq 1$) Lewis weights w, for any set of sampling probabilities p_i, $\sum_i p_i = N$,*

$$p_i \geq f(d, p) w_i,$$

if $S \in \mathbb{R}^{N \times n}$ has each row chosen independently as the i^{th} standard basis vector, multiplied by $1/p_i^{1/p}$, with probability p_i/N. Then, overall with probability at least 0.999,

$$\forall x \in \mathbb{R}^d, \frac{1}{2}\|Ax\|_p^p \leq \|SAx\|_p^p \leq 2\|Ax\|_p^p.$$

Furthermore, if $p = 1$, $N = O(d \log d)$. *If* $1 < p < 2$, $N = O(d \log d \log \log d)$. *If* $2 \leq p < 4$, $N = O(d^{p/2} \log d)$.

Lemma 21.3.14. *Given matrix* $A \in \mathbb{R}^{n \times d}$ $(n \geq d)$, *there is an algorithm to compute a diagonal matrix* $D = SS_1$ *with* N *nonzero entries in* $O(n \operatorname{poly}(d))$ *time such that, with probability at least* 0.999, *for all* $x \in \mathbb{R}^d$

$$\frac{1}{10}\|DAx\|_p^p \leq \|Ax\|_p^p \leq 10\|DAx\|_p^p,$$

where S, S_1 *are two sampling/rescaling matrices. Furthermore, if* $p = 1$, *then* $N = O(d \log d)$. *If* $1 < p < 2$, *then* $N = O(d \log d \log \log d)$. *If* $2 \leq p < 4$, *then* $N = O(d^{p/2} \log d)$.

Given a matrix $A \in \mathbb{R}^{n \times d}$ $(n \geq d)$, by Lemma 21.3.13 and Lemma 21.3.12, we can compute a sampling/rescaling matrix S in $O((nnz(A) + d^\omega \log d) \log n)$ time with $\widetilde{O}(d)$ nonzero entries such that

$$\forall x \in \mathbb{R}^d, \frac{1}{2}\|Ax\|_p^p \leq \|SAx\|_p^p \leq 2\|Ax\|_p^p.$$

Sometimes, $\operatorname{poly}(d)$ is much smaller than $\log n$. In this case, we are also able to compute such a sampling/rescaling matrix S in $n \operatorname{poly}(d)$ time in an alternative way.

To do so, we run one of the input sparsity ℓ_p embedding algorithms (see e.g., [MM13]) to compute a well conditioned basis U of the column span of A in $n \operatorname{poly}(d/\epsilon)$ time. By sampling according to the well conditioned basis (see e.g. [Cla05, DDH+09, Woo14b]), we can compute a sampling/rescaling matrix S_1 such that $(1-\epsilon)\|Ax\|_p^p \leq \|S_1 Ax\|_p^p \leq (1+\epsilon)\|Ax\|_p^p$ where $\epsilon \in (0, 1)$ is an arbitrary constant. Notice that S_1 has $\operatorname{poly}(d/\epsilon)$ nonzero entries, and thus $S_1 A$ has size $\operatorname{poly}(d/\epsilon)$. Next, we apply Lewis weight sampling according to $S_1 A$, and

we obtain a sampling/rescaling matrix S for which

$$\forall x \in \mathbb{R}^d, (1 - \frac{1}{3})\|S_1 Ax\|_p^p \leq \|SS_1 Ax\|_p^p \leq (1 + \frac{1}{3})\|S_1 Ax\|_p^p.$$

This implies that

$$\forall x \in \mathbb{R}^d, \frac{1}{2}\|Ax\|_p^p \leq \|SS_1 Ax\|_p^p \leq 2\|Ax\|_p^p.$$

Note that SS_1 is still a sampling/rescaling matrix according to A, and the number of non-zero entries is $\widetilde{O}(d)$. The total running time is thus $n\,\mathrm{poly}(d/\epsilon)$, as desired.

21.3.10 TensorSketch

Let $\phi(v_1, v_2, \cdots, v_q)$ denote the function that maps q vectors($u_i \in \mathbb{R}^{n_i}$) to the $\prod_{i=1}^{q} n_i$-dimensional vector formed by $v_1 \otimes v_2 \otimes \cdots \otimes u_q$.

We first give the definition of TensorSketch. Similar definitions can be found in previous work [Pag13, PP13, ANW14, WTSA15].

Definition 21.3.20 (TensorSketch [Pag13])**.** Given q points $v_1, v_2, \cdots, v_q$ where for each $i \in [q], v_i \in \mathbb{R}^{n_i}$, let m be the target dimension. The TensorSketch transform is specified using q 3-wise independent hash functions, $h_1, \cdots, h_q$, where for each $i \in [q]$, $h_i : [n_i] \to [m]$, as well as q 4-wise independent sign functions $s_1, \cdots, s_q$, where for each $i \in [q]$, $s_i : [n_i] \to \{-1, +1\}$.

TensorSketch applied to $v_1, \cdots, v_q$ is then CountSketch applied to $\phi(v_1, \cdots, v_q)$ with hash function $H : [\prod_{i=1}^{q} n_i] \to [m]$ and sign functions $S : [\prod_{i=1}^{q} n_i] \to \{-1, +1\}$ defined as follows:

$$H(i_1, \cdots, i_q) = h_1(i_1) + h_2(s_2) + \cdots + h_q(i_q) \pmod{m},$$

and

$$S(i_1, \cdots, i_q) = s_1(i_1) \cdot s_2(i_2) \cdot \cdots \cdot s_q(i_q).$$

Using the Fast Fourier Transform, TensorSketch$(v_1, \cdots, v_q)$ can be computed in $O(\sum_{i=1}^{q}(\text{nnz}(v_i) + m \log m))$ time.

Note that Theorem 1 in [ANW14] only defines $\phi(v) = v \otimes v \otimes \cdots \otimes v$. Here we state a stronger version of Theorem 1 than in [ANW14], though the proofs are identical; a formal derivation can be found in [DW17].

Theorem 21.3.15 (Generalized version of Theorem 1 in [ANW14]). *Let S be the $(\prod_{i=1}^{q} n_i) \times m$ matrix such that* TensorSketch *$(v_1, v_2, \cdots, v_q)$ is $\phi(v_1, v_2, \cdots, v_q)S$ for a randomly selected* TensorSketch. *The matrix S satisfies the following two properties.*

Property I (Approximate Matrix Product). Let A and B be matrices with $\prod_{i=1}^{q} n_i$ rows. For $m \geq (2 + 3^q)/(\epsilon^2 \delta)$, we have

$$\Pr[\|A^\top S S^\top B - A^\top B\|_F^2 \leq \epsilon^2 \|A\|_F^2 \|B\|_F^2] \geq 1 - \delta.$$

Property II (Subspace Embedding). Consider a fixed k-dimensional subspace V. If $m \geq k^2(2+3^q)/(\epsilon^2\delta)$, then with probability at least $1-\delta$, $\|xS\|_2 = (1 \pm \epsilon)\|x\|_2$ simultaneously for all $x \in V$.

21.4 Frobenius Norm for Arbitrary Tensors

Section 21.4.1 presents a Frobenius norm tensor low-rank approximation algorithm with $(1+\epsilon)$-approximation ratio. Section 21.4.2 introduces a tool which is able to reduce the size of the objective function from n^3 to $\text{poly}(k, 1/\epsilon)$. Section 21.4.3 introduces a new problem called tensor multiple regression. Section 21.4.4 presents several bicriteria algorithms. Section 21.4.5 introduces a powerful tool which we call generalized matrix row subset selection. Section 21.4.6 presents an algorithm that is able to select a batch of columns, rows and tubes from a given tensor, and those samples are also able to form a low-rank solution. Section 21.4.7 presents several useful tools for tensor problems, and also two $(1+\epsilon)$-approximation CURT decomposition algorithms: one has the optimal sample complexity, and the other has the optimal running time. Section 21.4.9 shows how to solve the problem if the size of the objective function is small. Section 21.5 extends several techniques from 3rd order tensors to general q-th order tensors, for any $q \geq 3$. Finally, in Section 21.6 we also provide a new matrix CUR decomposition algorithm, which is faster than [BW14].

For simplicity of presentation, we assume A_k exists in theorems (e.g., Theorem 21.4.1) which concern outputting a rank-k solution, as well as the theorems (e.g., Theorem 21.4.7, Theorem 21.4.8, Theorem 21.4.13) which concern outputting a bicriteria solution (the output rank is larger than k). For each of the bicriteria theorems, we can obtain a more detailed version when A_k does not exist, like Theorem 21.1.1 in Section 21.1 (by instead considering a tensor sufficiently close to A_k in objective function value). Note that the theorems for column, row, tube subset selection Theorem 21.4.20 and Theorem 21.4.21 also belong to this first category. In the second category, for each of the rank-k theorems we can obtain a more detailed version handling all cases, even when A_k does not exist, like Theorem 21.1.2

in Section 21.1 (by instead considering a tensor sufficiently close to A_k in objective function value).

Several other tensor results or tools (e.g., Theorem 21.4.4, Lemma 21.4.3, Theorem 21.4.39, Theorem 21.4.40, Theorem 21.4.14, Theorem 21.5.1) that we build in this section do not belong to the above two categories. It means those results do not depend on whether A_k exists or not and whether OPT is zero or not.

21.4.1 $(1+\epsilon)$-approximate low-rank approximation

Algorithm 21.2 Frobenius Norm Low-rank Approximation

procedure FLowRankApprox(A, n, k, ϵ) ▷ Theorem 21.4.1

  Choose sketching matrices $S_1 \in \mathbb{R}^{n^2 \times s_1}$, $S_2 \in \mathbb{R}^{n^2 \times s_2}$, $S_3 \in \mathbb{R}^{n^2 \times s_3}$. ▷ Definition 21.3.12
  Compute $A_i S_i, \forall i \in [3]$.
  $Y_1, Y_2, Y_3, C \leftarrow$FInputSparsityReduction$(A, A_1S_1, A_2S_2, A_3S_3, n, s_1, s_2, s_3, k, \epsilon)$. ▷ Algorithm 21.3
  Create variables for $X_i \in \mathbb{R}^{s_i \times k}, \forall i \in [3]$.
  Run polynomial system verifier for $\|(Y_1X_1) \otimes (Y_2X_2) \otimes (Y_3X_3) - C\|_F^2$.
  return $A_1S_1X_1$, $A_2S_2X_2$, and $A_3S_3X_3$.
end procedure

Theorem 21.4.1. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1, \epsilon \in (0,1)$, there exists an algorithm which takes $O(\mathrm{nnz}(A)) + n\,\mathrm{poly}(k, 1/\epsilon) + 2^{O(k^2/\epsilon)}$ time and outputs three matrices $U \in \mathbb{R}^{n \times k}$, $V \in \mathbb{R}^{n \times k}$, $W \in \mathbb{R}^{n \times k}$ such that*

$$\left\| \sum_{i=1}^{k} U_i \otimes V_i \otimes W_i - A \right\|_F^2 \leq (1+\epsilon) \min_{\mathrm{rank}-k\ A_k} \|A_k - A\|_F^2$$

holds with probability $9/10$.

Proof. Given any tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, we define three matrices $A_1 \in \mathbb{R}^{n_1 \times n_2 n_3}, A_2 \in \mathbb{R}^{n_2 \times n_3 n_1}, A_3 \in \mathbb{R}^{n_3 \times n_1 n_2}$ such that, for any $i \in [n_1], j \in [n_2], l \in [n_3]$,

$$A_{i,j,l} = (A_1)_{i,(j-1)\cdot n_3 + l} = (A_2)_{j,(l-1)\cdot n_1 + i} = (A_3)_{l,(i-1)\cdot n_2 + j}.$$

We define OPT as

$$\mathrm{OPT} = \min_{\mathrm{rank}-k\ A'} \|A' - A\|_F^2.$$

Suppose the optimal $A_k = U^* \otimes V^* \otimes W^*$. We fix $V^* \in \mathbb{R}^{n\times k}$ and $W^* \in \mathbb{R}^{n\times k}$. We use $V_1^*, V_2^*, \cdots, V_k^*$ to denote the columns of V^* and $W_1^*, W_2^*, \cdots, W_k^*$ to denote the columns of W^*.

We consider the following optimization problem,

$$\min_{U_1,\cdots,U_k\in\mathbb{R}^n} \left\| \sum_{i=1}^k U_i \otimes V_i^* \otimes W_i^* - A \right\|_F^2,$$

which is equivalent to

$$\min_{U_1,\cdots,U_k\in\mathbb{R}^n} \left\| \begin{bmatrix} U_1 & U_2 & \cdots & U_k \end{bmatrix} \begin{bmatrix} V_1^* \otimes W_1^* \\ V_2^* \otimes W_2^* \\ \cdots \\ V_k^* \otimes W_k^* \end{bmatrix} - A \right\|_F^2.$$

We use matrix Z_1 to denote $\begin{bmatrix} \mathrm{vec}(V_1^* \otimes W_1^*) \\ \mathrm{vec}(V_2^* \otimes W_2^*) \\ \cdots \\ \mathrm{vec}(V_k^* \otimes W_k^*) \end{bmatrix} \in \mathbb{R}^{k\times n^2}$ and matrix U to denote $\begin{bmatrix} U_1 & U_2 & \cdots & U_k \end{bmatrix}$. Then we can obtain the following equivalent objective function,

$$\min_{U\in\mathbb{R}^{n\times k}} \|UZ_1 - A_1\|_F^2.$$

Notice that $\min_{U\in\mathbb{R}^{n\times k}} \|UZ_1 - A_1\|_F^2 = \mathrm{OPT}$, since $A_k = U^* Z_1$.

Let $S_1^\top \in \mathbb{R}^{s_1\times n^2}$ be a sketching matrix defined in Definition 21.3.12, where $s_1 = O(k/\epsilon)$. We obtain the following optimization problem,

$$\min_{U\in\mathbb{R}^{n\times k}} \|UZ_1S_1 - A_1S_1\|_F^2.$$

Let $\widehat{U} \in \mathbb{R}^{n\times k}$ denote the optimal solution to the above optimization problem. Then $\widehat{U} = A_1S_1(Z_1S_1)^\dagger$. By Lemma 21.3.10 and Theorem 21.3.11, we have

$$\|\widehat{U}Z_1 - A_1\|_F^2 \leq (1+\epsilon) \min_{U \in \mathbb{R}^{n \times k}} \|UZ_1 - A_1\|_F^2 = (1+\epsilon)\,\mathrm{OPT},$$

which implies

$$\left\| \sum_{i=1}^{k} \widehat{U}_i \otimes V_i^* \otimes W_i^* - A \right\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}\,.$$

To write down $\widehat{U}_1, \cdots, \widehat{U}_k$, we use the given matrix A_1, and we create $s_1 \times k$ variables for matrix $(Z_1 S_1)^\dagger$.

As our second step, we fix $\widehat{U} \in \mathbb{R}^{n \times k}$ and $W^* \in \mathbb{R}^{n \times k}$, and we convert tensor A into matrix A_2. Let matrix Z_2 denote $\begin{bmatrix} \mathrm{vec}(\widehat{U}_1 \otimes W_1^*) \\ \mathrm{vec}(\widehat{U}_2 \otimes W_2^*) \\ \cdots \\ \mathrm{vec}(\widehat{U}_k \otimes W_k^*) \end{bmatrix}$. We consider the following objective function,

$$\min_{V \in \mathbb{R}^{n \times k}} \|VZ_2 - A_2\|_F^2,$$

for which the optimal cost is at most $(1+\epsilon)\,\mathrm{OPT}$.

Let $S_2^\top \in \mathbb{R}^{s_2 \times n^2}$ be a sketching matrix defined in Definition 21.3.12, where $s_2 = O(k/\epsilon)$. We sketch S_2 on the right of the objective function to obtain the new objective function,

$$\min_{V \in \mathbb{R}^{n \times k}} \|VZ_2S_2 - A_2S_2\|_F^2.$$

Let $\widehat{V} \in \mathbb{R}^{n \times k}$ denote the optimal solution of the above problem. Then $\widehat{V} = A_2S_2(Z_2S_2)^\dagger$. By Lemma 21.3.10 and Theorem 21.3.11, we have,

$$\|\widehat{V}Z_2 - A_2\|_F^2 \leq (1+\epsilon) \min_{V \in \mathbb{R}^{n \times k}} \|VZ_2 - A_2\|_F^2 \leq (1+\epsilon)^2\,\mathrm{OPT},$$

which implies

$$\left\|\sum_{i=1}^{k} \widehat{U}_i \otimes \widehat{V}_i \otimes W_i^* - A\right\|_F^2 \leq (1+\epsilon)^2 \operatorname{OPT}.$$

To write down $\widehat{V}_1, \cdots, \widehat{V}_k$, we need to use the given matrix $A_2 \in \mathbb{R}^{n^2 \times n}$, and we need to create $s_2 \times k$ variables for matrix $(Z_2 S_2)^\dagger$.

As our third step, we fix the matrices $\widehat{U} \in \mathbb{R}^{n \times k}$ and $\widehat{V} \in \mathbb{R}^{n \times k}$. We convert tensor $A \in \mathbb{R}^{n \times n \times n}$ into matrix $A_3 \in \mathbb{R}^{n^2 \times n}$. Let matrix Z_3 denote $\begin{bmatrix} \operatorname{vec}(\widehat{U}_1 \otimes \widehat{V}_1) \\ \operatorname{vec}(\widehat{U}_2 \otimes \widehat{V}_2) \\ \cdots \\ \operatorname{vec}(\widehat{U}_k \otimes \widehat{V}_k) \end{bmatrix}$. We consider the following objective function,

$$\min_{W \in \mathbb{R}^{n \times k}} \|W Z_3 - A_3\|_F^2,$$

which has optimal cost at most $(1+\epsilon)^2 \operatorname{OPT}$.

Let $S_3^\top \in \mathbb{R}^{s_3 \times n^2}$ be a sketching matrix defined in Definition 21.3.12, where $s_3 = O(k/\epsilon)$. We sketch S_3 on the right of the objective function to obtain a new objective function,

$$\min_{W \in \mathbb{R}^{n \times k}} \|W Z_3 S_3 - A_3 S_3\|_F^2.$$

Let $\widehat{W} \in \mathbb{R}^{n \times k}$ denote the optimal solution of the above problem. Then $\widehat{W} = A_3 S_3 (Z_3 S_3)^\dagger$. By Lemma 21.3.10 and Theorem 21.3.11, we have,

$$\|\widehat{W} Z_3 - A_3\|_F^2 \leq (1+\epsilon) \min_{W \in \mathbb{R}^{n \times k}} \|W Z_3 - A_3\|_F^2 \leq (1+\epsilon)^3 \operatorname{OPT}.$$

Thus, we have

$$\min_{X_1, X_2, X_3} \left\|\sum_{i=1}^{k} (A_1 S_1 X_1)_i \otimes (A_2 S_2 X_2)_i \otimes (A_3 S_3 X_3)_i - A\right\|_F^2 \leq (1+\epsilon)^3 \operatorname{OPT}.$$

Let $V_1 = A_1 S_1, V_2 = A_2 S_2, V_3 = A_3 S_3$, we then apply Lemma 21.4.3, and we obtain $\widehat{V}_1, \widehat{V}_2, \widehat{V}_3, C$. We then apply Theorem 21.4.44. Correctness follows by rescaling ϵ by a constant factor.

Running time. Due to Definition 21.3.12, the running time of line 4 is $O(\mathrm{nnz}(A)) + n\,\mathrm{poly}(k)$. The running time of line 5 is shown by Lemma 21.4.3, and the running time of line 7 is shown by Theorem 21.4.44. □

Theorem 21.4.2. *Suppose we are given a 3rd order $n \times n \times n$ tensor A such that each entry can be written using n^δ bits, where $\delta > 0$ is a given, value which can be arbitrarily small (e.g., we could have n^δ being $O(\log n)$). Define $\mathrm{OPT} = \inf_{\mathrm{rank}-k\ A_k} \|A_k - A\|_F^2$. For any $k \geq 1$, and for any $0 < \epsilon < 1$, define $n^{\delta'} = O(n^\delta 2^{O(k^2/\epsilon)})$. (I) If $\mathrm{OPT} > 0$, and there exists a rank-k $A_k = U^* \otimes V^* \otimes W^*$ tensor, with size $n \times n \times n$, such that $\|A_k - A\|_F^2 = \mathrm{OPT}$, and $\max(\|U^*\|_F, \|V^*\|_F, \|W^*\|_F) \leq 2^{O(n^{\delta'})}$, then there exists an algorithm that takes $(\mathrm{nnz}(A) + n\,\mathrm{poly}(k, 1/\epsilon) + 2^{O(k^2/\epsilon)})n^\delta$ time in the unit cost* RAM *model with word size $O(\log n)$ bits*[9] *and outputs three $n \times k$ matrices U, V, W such that*

$$\|U \otimes V \otimes W - A\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT} \tag{21.5}$$

holds with probability $9/10$, and each entry of each of U, V, W fits in $n^{\delta'}$ bits.

(II) *If $\mathrm{OPT} > 0$, and A_k does not exist, and there exist three $n \times k$ matrices U', V', W' for which $\max(\|U'\|_F, \|V'\|_F, \|W'\|_F) \leq 2^{O(n^{\delta'})}$ and $\|U' \otimes V' \otimes W' - A\|_F^2 \leq (1 + \epsilon/2)\,\mathrm{OPT}$, then we can find U, V, W such that (21.5) holds.*

[9] The entries of A are assumed to fit in n^δ words.

(III) *If* $\mathrm{OPT} = 0$ *and* A_k *does exist, and there exists a solution* U^*, V^*, W^* *such that each entry can be written by* $n^{\delta'}$ *bits, then we can obtain* (21.5).

(IV) *If* $\mathrm{OPT} = 0$*, and there exist three* $n \times k$ *matrices* U, V, W *such that*

$$\max(\|U\|_F, \|V\|_F, \|W\|_F) \leq 2^{O(n^{\delta'})}$$

and

$$\|U \otimes V \otimes W - A\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT} + 2^{-\Omega(n^{\delta'})} = 2^{-\Omega(n^{\delta'})}, \tag{21.6}$$

then we can output U, V, W *such that* (21.6) *holds.*

Further if A_k *exists, we can output a number* Z *for which* $\mathrm{OPT} \leq Z \leq (1+\epsilon)\,\mathrm{OPT}$*. For all the cases above, the algorithm runs in the same time as (I) and succeeds with probability at least* $9/10$*.*

Proof. This follows by the discussion in Section 21.1, Theorem 21.4.1 and Theorem 21.4.44 in Section 21.4.9.

Part (I) Suppose $\delta > 0$ and $A_k = U^* \otimes V^* \otimes W^*$ exists and each of $\|U^*\|_F$, $\|V^*\|_F$, and $\|W^*\|_F$ is bounded by $2^{O(n^{\delta'})}$. We assume the computation model is the unit cost RAM model with words of size $O(\log n)$ bits, and allow each number of the input tensor A to be written using n^{δ} bits. For the case when OPT is nonzero, using the proof of Theorem 21.4.1 and Theorems 21.4.44, 21.3.2, there exists a lower bound on the cost OPT, which is at least $2^{-O(n^{\delta})2^{O(k^2/\epsilon)}}$. We can round each entry of matrices U^*, V^*, W^* to be an integer expressed using $O(n^{\delta'})$ bits to obtain U', V', W'. Using the triangle inequality and our lower bound on OPT, it follows that U', V', W' provide a $(1+\epsilon)$-approximation.

Thus, applying Theorem 21.4.1 by fixing U', V', W' and using Theorem 21.4.44 at the end, we can output three matrices U, V, W, where each entry can be written using $n^{\delta'}$ bits, so that we satisfy $\|U \otimes V \otimes W - A\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}$.

For the running time, since each entry of the input is bounded by n^{δ} bits, due to Theorem 21.4.1, we need $(\mathrm{nnz}(A) + n\,\mathrm{poly}(k/\epsilon)) \cdot n^{\delta}$ time to reduce the size of the problem to $\mathrm{poly}(k/\epsilon)$ size (with each number represented using $O(n^{\delta})$ bits). According to Theorem 21.4.44, the running time of using a polynomial system verifier to get the solution is $2^{O(k^2/\epsilon)} n^{O(\delta')} = 2^{O(k^2/\epsilon)} n^{O(\delta)}$ time. Thus the total running time is $(\mathrm{nnz}(A) + n\,\mathrm{poly}(k/\epsilon))n^{\delta} + 2^{O(k^2/\epsilon)} \cdot n^{O(\delta)}$.

Part (II) is similar to Part (I). Part (III) is trivial to prove since there exists a solution which can be written down in the bit model, so we obtain a $(1+\epsilon)$-approximation. Part (IV) is also very similar to Part (II).

□

21.4.2 Input sparsity reduction

Algorithm 21.3 Reducing the Size of the Objective Function from poly(n) to poly(k)

procedure FInputSparsityReduction$(A, V_1, V_2, V_3, n, b_1, b_2, b_3, k, \epsilon)$ ▷ Lemma 21.4.3
  $c_1 \leftarrow c_2 \leftarrow c_3 \leftarrow \text{poly}(k, 1/\epsilon)$.
  Choose sparse embedding matrices $T_1 \in \mathbb{R}^{c_1 \times n}$, $T_2 \in \mathbb{R}^{c_2 \times n}$, $T_3 \in \mathbb{R}^{c_3 \times n}$. ▷ Definition 21.3.10
  $\widehat{V}_i \leftarrow T_i V_i \in \mathbb{R}^{c_i \times b_i}, \forall i \in [3]$.
  $C \leftarrow A(T_1, T_2, T_3) \in \mathbb{R}^{c_1 \times c_2 \times c_3}$.
  return $\widehat{V}_1$, $\widehat{V}_2$, $\widehat{V}_3$ and C.
end procedure

Lemma 21.4.3. *Let* $\text{poly}(k, 1/\epsilon) \geq b_1 b_2 b_3 \geq k$. *Given a tensor* $A \in \mathbb{R}^{n \times n \times n}$ *and three matrices* $V_1 \in \mathbb{R}^{n \times b_1}$, $V_2 \in \mathbb{R}^{n \times b_2}$, *and* $V_3 \in \mathbb{R}^{n \times b_3}$, *there exists an algorithm that takes* $O(\text{nnz}(A) + \text{nnz}(V_1) + \text{nnz}(V_2) + \text{nnz}(V_3)) = O(\text{nnz}(A) + n\,\text{poly}(k/\epsilon))$ *time and outputs a tensor* $C \in \mathbb{R}^{c_1 \times c_2 \times c_3}$ *and three matrices* $\widehat{V}_1 \in \mathbb{R}^{c_1 \times b_1}$, $\widehat{V}_2 \in \mathbb{R}^{c_2 \times b_2}$ *and* $\widehat{V}_3 \in \mathbb{R}^{c_3 \times b_3}$ *with* $c_1 = c_2 = c_3 = \text{poly}(k, 1/\epsilon)$, *such that with probability at least* 0.99, *for all* $\alpha > 0, X_1, X_1' \in \mathbb{R}^{b_1 \times k}, X_2, X_2' \in \mathbb{R}^{b_2 \times k}, X_3, X_3' \in \mathbb{R}^{b_3 \times k}$ *satisfy that,*

$$\left\| \sum_{i=1}^k (\widehat{V}_1 X_1')_i \otimes (\widehat{V}_2 X_2')_i \otimes (\widehat{V}_3 X_3')_i - C \right\|_F^2 \leq \alpha \left\| \sum_{i=1}^k (\widehat{V}_1 X_1)_i \otimes (\widehat{V}_2 X_2)_i \otimes (\widehat{V}_3 X_3)_i - C \right\|_F^2,$$

then,

$$\left\| \sum_{i=1}^k (V_1 X_1')_i \otimes (V_2 X_2')_i \otimes (V_3 X_3')_i - A \right\|_F^2 \leq (1+\epsilon)\alpha \left\| \sum_{i=1}^k (V_1 X_1)_i \otimes (V_2 X_2)_i \otimes (V_3 X_3)_i - A \right\|_F^2.$$

Proof. Let $X_1 \in \mathbb{R}^{b_1 \times k}, X_2 \in \mathbb{R}^{b_2 \times k}, X_3 \in \mathbb{R}^{b_3 \times k}$. First, we define $Z_1 = ((V_2 X_2)^\top \odot (V_3 X_3)^\top) \in \mathbb{R}^{k \times n^2}$. (Note that, for each $i \in [k]$, the i-th row of matrix Z_1 is $\text{vec}((V_2 X_2)_i \otimes (V_3 X_3)_i)$.) Then, by flattening we have

$$\left\| \sum_{i=1}^k (V_1 X_1)_i \otimes (V_2 X_2)_i \otimes (V_3 X_3)_i - A \right\|_F^2 = \|V_1 X_1 \cdot Z_1 - A_1\|_F^2.$$

We choose a sparse embedding matrix (Definition 21.3.10) $T_1 \in \mathbb{R}^{c_1 \times n}$ with $c_1 = \text{poly}(k, 1/\epsilon)$ rows. Since V_1 has $b_1 \leq \text{poly}(k/\epsilon)$ columns, according to Lemma 21.3.7 with probability 0.999, for all $X_1 \in \mathbb{R}^{b_1 \times k}, Z \in \mathbb{R}^{k \times n^2}$,

$$(1-\epsilon)\|V_1 X_1 Z - A_1\|_F^2 \leq \|T_1 V_1 X_1 Z - T_1 A_1\|_F^2 \leq (1+\epsilon)\|V_1 X_1 Z - A_1\|_F^2.$$

Therefore, we have

$$\|T_1 V_1 X_1 \cdot Z_1 - T_1 A_1\|_F^2 = (1 \pm \epsilon) \left\| \sum_{i=1}^k (V_1 X_1)_i \otimes (V_2 X_2)_i \otimes (V_3 X_3)_i - A \right\|_F^2.$$

Second, we unflatten matrix $T_1 A_1 \in \mathbb{R}^{c_1 \times n^2}$ to obtain a tensor $A' \in \mathbb{R}^{c_1 \times n \times n}$. Then we flatten A' along the second direction to obtain $A_2 \in \mathbb{R}^{n \times c_1 n}$. We define $Z_2 = (T_1 V_1 X_1)^\top \odot (V_3 X_3)^\top \in \mathbb{R}^{k \times c_1 n}$. Then, by flattening,

$$\begin{aligned} \|V_2 X_2 \cdot Z_2 - A_2\|_F^2 &= \|T_1 V_1 X_1 \cdot Z_1 - T_1 A_1\|_F^2 \\ &= (1 \pm \epsilon) \left\| \sum_{i=1}^k (V_1 X_1)_i \otimes (V_2 X_2)_i \otimes (V_3 X_3)_i - A \right\|_F^2. \end{aligned}$$

We choose a sparse embedding matrix (Definition 21.3.10) $T_2 \in \mathbb{R}^{c_2 \times n}$ with $c_2 = \text{poly}(k, 1/\epsilon)$ rows. Then according to Lemma 21.3.7 with probability 0.999, for all $X_2 \in \mathbb{R}^{b_2 \times k}$, $Z \in \mathbb{R}^{k \times c_1 n}$,

$$(1-\epsilon)\|V_2 X_2 Z - A_2\|_F^2 \leq \|T_2 V_2 X_2 Z - T_2 A_2\|_F^2 \leq (1+\epsilon)\|V_2 X_2 Z - A_2\|_F^2.$$

Therefore, we have

$$\begin{aligned} \|T_2 V_2 X_2 \cdot Z_2 - T_2 A_2\|_F^2 &= (1 \pm \epsilon)\|V_2 X_2 \cdot Z_2 - A_2\|_F^2 \\ &= (1 \pm \epsilon)^2 \left\| \sum_{i=1}^k (V_1 X_1)_i \otimes (V_2 X_2)_i \otimes (V_3 X_3)_i - A \right\|_F^2. \end{aligned}$$

Third, we unflatten matrix $T_2A_2 \in \mathbb{R}^{c_2 \times c_1 n}$ to obtain a tensor $A''(= A(T_1, T_2, I)) \in \mathbb{R}^{c_1 \times c_2 \times n}$. Then we flatten tensor A'' along the last direction (the third direction) to obtain matrix $A_3 \in \mathbb{R}^{n \times c_1 c_2}$. We define $Z_3 = (T_1V_1X_1)^\top \odot (T_2V_2X_2)^\top \in \mathbb{R}^{k \times c_1 c_2}$. Then, by flattening, we have

$$\begin{aligned}\|V_3X_3 \cdot Z_3 - A_3\|_F^2 = & \|T_2V_2X_2 \cdot Z_2 - T_2A_2\|_F^2 \\ = & (1 \pm \epsilon)^2 \left\| \sum_{i=1}^k (V_1X_1)_i \otimes (V_2X_2)_i \otimes (V_3X_3)_i - A \right\|_F^2.\end{aligned}$$

We choose a sparse embedding matrix (Definition 21.3.10) $T_3 \in \mathbb{R}^{c_3 \times n}$ with $c_3 = \mathrm{poly}(k, 1/\epsilon)$ rows. Then according to Lemma 21.3.7 with probability 0.999, for all $X_3 \in \mathbb{R}^{b_3 \times k}$, $Z \in \mathbb{R}^{k \times c_1 c_2}$,

$$(1-\epsilon)\|V_3X_3Z - A_3\|_F^2 \leq \|T_3V_3X_3Z - T_3A_3\|_F^2 \leq (1+\epsilon)\|V_3X_3Z - A_3\|_F^2.$$

Therefore, we have

$$\|T_3V_3X_3 \cdot Z_3 - T_3A_3\|_F^2 = (1 \pm \epsilon)^3 \left\| \sum_{i=1}^k (V_1X_1)_i \otimes (V_2X_2)_i \otimes (V_3X_3)_i - A \right\|_F^2.$$

Note that

$$\|T_3V_3X_3 \cdot Z_3 - T_3A_3\|_F^2 = \left\| \sum_{i=1}^k (T_1V_1X_1)_i \otimes (T_2V_2X_2)_i \otimes (T_3V_3X_3)_i - A(T_1, T_2, T_3) \right\|_F^2,$$

and thus, we have $\forall X_1 \in \mathbb{R}^{b_1 \times k}, X_2 \in \mathbb{R}^{b_2 \times k}, X_3 \in \mathbb{R}^{b_3 \times k}$

$$\begin{aligned}& \left\| \sum_{i=1}^k (T_1V_1X_1)_i \otimes (T_2V_2X_2)_i \otimes (T_3V_3X_3)_i - A(T_1, T_2, T_3) \right\|_F^2 \\ = & (1 \pm \epsilon)^3 \left\| \sum_{i=1}^k (V_1X_1)_i \otimes (V_2X_2)_i \otimes (V_3X_3)_i - A \right\|_F^2.\end{aligned}$$

Let $\widehat{V}_i$ denote $T_i V_i$, for each $i \in [3]$. Let $C \in \mathbb{R}^{c_1 \times c_2 \times c_3}$ denote $A(T_1, T_2, T_3)$. For $\alpha > 1$, if

$$\left\| \sum_{i=1}^k (\widehat{V}_1 X_1')_i \otimes (\widehat{V}_2 X_2')_i \otimes (\widehat{V}_3 X_3')_i - C \right\|_F^2 \leq \alpha \left\| \sum_{i=1}^k (\widehat{V}_1 X_1)_i \otimes (\widehat{V}_2 X_2)_i \otimes (\widehat{V}_3 X_3)_i - C \right\|_F^2,$$

then

$$\begin{aligned}
& \left\| \sum_{i=1}^k (V_1 X_1')_i \otimes (V_2 X_2')_i \otimes (V_3 X_3')_i - C \right\|_F^2 \\
\leq & \frac{1}{(1-\epsilon)^3} \left\| \sum_{i=1}^k (\widehat{V}_1 X_1')_i \otimes (\widehat{V}_2 X_2')_i \otimes (\widehat{V}_3 X_3')_i - C \right\|_F^2 \\
\leq & \frac{1}{(1-\epsilon)^3} \alpha \left\| \sum_{i=1}^k (\widehat{V}_1 X_1)_i \otimes (\widehat{V}_2 X_2)_i \otimes (\widehat{V}_3 X_3)_i - C \right\|_F^2 \\
\leq & \frac{(1+\epsilon)^3}{(1-\epsilon)^3} \alpha \left\| \sum_{i=1}^k (V_1 X_1)_i \otimes (V_2 X_2)_i \otimes (V_3 X_3)_i - C \right\|_F^2
\end{aligned}$$

By rescaling ϵ by a constant, we complete the proof of correctness.

Running time. According to Section 21.3.6, for each $i \in [3]$, $T_i V_i$ can be computed in $O(\mathrm{nnz}(V_i))$ time, and $A(T_1, T_2, T_3)$ can be computed in $O(\mathrm{nnz}(A))$ time.

By the analysis above, the proof is complete. □

21.4.3 Tensor multiple regression

Algorithm 21.4 Frobenius Norm Tensor Multiple Regression

procedure FTensorMultipleRegression(A, U, V, d, n, k) ▷ Theorem 21.4.4
  $s \leftarrow O(k^2 + k/\epsilon)$.
  Choose $S \in \mathbb{R}^{n^2 \times s}$ to be a TensorSketch. ▷ Definition 21.3.20
  Compute $A \cdot S$.
  Compute $B \cdot S$. ▷ $B = U^\top \odot V^\top$
  $W \leftarrow (AS)(BS)^\dagger$
  return W.
end procedure

Theorem 21.4.4. *Given matrices $A \in \mathbb{R}^{d \times n^2}$, $U, V \in \mathbb{R}^{n \times k}$, let $B \in \mathbb{R}^{k \times n^2}$ denote $U^\top \odot V^\top$. There exists an algorithm that takes $O(\mathrm{nnz}(A) + \mathrm{nnz}(U) + \mathrm{nnz}(V) + d\,\mathrm{poly}(k, 1/\epsilon))$ time and outputs a matrix $W' \in \mathbb{R}^{d \times k}$ such that,*

$$\|W'B - A\|_F^2 \leq (1+\epsilon) \min_{W \in \mathbb{R}^{d \times k}} \|WB - A\|_F^2.$$

Proof. We choose a TensorSketch (Definition 21.3.20) $S \in \mathbb{R}^{n^2 \times s}$ to reduce the problem to a smaller problem,

$$\min_{W \in \mathbb{R}^{d \times k}} \|WBS - AS\|_F^2.$$

Let W' denote the optimal solution to the above problem. Following a similar proof to that in Section 21.4.7.3, if S is a $(1 \pm 1/2)$-subspace embedding and satisfies $\sqrt{\epsilon/k}$-approximate matrix product, then W' provides a $(1+\epsilon)$-approximation to the original problem. By Theorem 21.3.15, we have $s = O(k^2 + k/\epsilon)$.

Running time. According to Definition 21.3.20, BS can be computed in $O(\text{nnz}(U) + \text{nnz}(V)) + \text{poly}(k/\epsilon)$ time. Notice that each row of S has exactly 1 nonzero entry, thus AS can be computed in $O(\text{nnz}(A))$ time. Since $BS \in \mathbb{R}^{k \times s}$ and $AS \in \mathbb{R}^{d \times s}$, $\min_{W \in \mathbb{R}^{d \times k}} \|WBS - AS\|_F^2$ can be solved in $d\,\text{poly}(sk) = d\,\text{poly}(k/\epsilon)$ time. □

21.4.4 Bicriteria algorithms

21.4.4.1 Solving a small regression problem

Lemma 21.4.5. *Given tensor $A \in \mathbb{R}^{n\times n\times n}$ and three matrices $U \in \mathbb{R}^{n\times s_1}, V \in \mathbb{R}^{n\times s_2}$ and $W \in \mathbb{R}^{n\times s_3}$, there exists an algorithm that takes $O(\mathrm{nnz}(A) + n\,\mathrm{poly}(s_1, s_2, s_3, 1/\epsilon))$ time and outputs $\alpha' \in \mathbb{R}^{s_1\times s_2\times s_3}$ such that*

$$\left\| \sum_{i=1}^{s_1}\sum_{j=1}^{s_2}\sum_{l=1}^{s_3} \alpha'_{i,j,l} \cdot U_i \otimes V_j \otimes W_l - A \right\|_F^2$$
$$\leq (1+\epsilon) \min_{\alpha\in\mathbb{R}^{s_1\times s_2\times s_3}} \left\| \sum_{i=1}^{s_1}\sum_{j=1}^{s_2}\sum_{l=1}^{s_3} \alpha_{i,j,l} \cdot U_i \otimes V_j \otimes W_l - A \right\|_F^2.$$

holds with probability at least .99.

Proof. We define $\widetilde{b} \in \mathbb{R}^{n^3}$ to be the vector where the $i+(j-1)n+(l-1)n^2$-th entry of $\widetilde{b}$ is $A_{i,j,l}$. We define $\widetilde{A} \in \mathbb{R}^{n^3\times s_1 s_2 s_3}$ to be the matrix where the $(i+(j-1)n+(l-1)n^2, i'+(j'-1)s_2+(l'-1)s_2s_3)$ entry is $U_{i',i} \cdot V_{j',j} \cdot W_{l',l}$. This problem is equivalent to a linear regression problem,

$$\min_{x\in\mathbb{R}^{s_1 s_2 s_3}} \|\widetilde{A}x - \widetilde{b}\|_2^2,$$

where $\widetilde{A} \in \mathbb{R}^{n^3\times s_1 s_2 s_3}, \widetilde{b} \in \mathbb{R}^{n^3}$. Thus, it can be solved fairly quickly using recent work [CW13, MM13, NN13a]. However, the running time of this naïvely is $\Omega(n^3)$, since we have to write down each entry of $\widetilde{A}$. In the next few paragraphs, we show how to improve the running time to $\mathrm{nnz}(A) + n\,\mathrm{poly}(s_1, s_2, s_3)$.

Since $\alpha \in \mathbb{R}^{s_1\times s_2\times s_3}$, α can be always written as $\alpha = X_1 \otimes X_2 \otimes X_3$, where $X_1 \in$

$\mathbb{R}^{s_1 \times s_1 s_2 s_3}, X_2 \in \mathbb{R}^{s_2 \times s_1 s_2 s_3}, X_3 \in \mathbb{R}^{s_3 \times s_1 s_2 s_3}$, we have

$$\begin{aligned}
&\min_{\alpha \in \mathbb{R}^{s_1 \times s_2 \times s_3}} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} \alpha_{i,j,l} \cdot U_i \otimes V_j \otimes W_l - A \right\|_F^2 \\
= &\min_{\substack{X_1 \in \mathbb{R}^{s_1 \times s_1 s_2 s_3} \\ X_2 \in \mathbb{R}^{s_2 \times s_1 s_2 s_3} \\ X_3 \in \mathbb{R}^{s_3 \times s_1 s_2 s_3}}} \|(UX_1) \otimes (VX_2) \otimes (WX_3) - A\|_F^2 .
\end{aligned}$$

By Lemma 21.4.3, we can reduce the problem size $n \times n \times n$ to a smaller problem that has size $t_1 \times t_2 \times t_3$,

$$\min_{X_1, X_2, X_3} \left\| \sum_{i=1}^{s_1 s_2 s_3} (T_1 U X_1)_i \otimes (T_2 V X_2)_i \otimes (T_3 W X_3)_i - A(T_1, T_2, T_3) \right\|_F^2$$

where $T_1 \in \mathbb{R}^{t_1 \times n}$, $T_2 \in \mathbb{R}^{t_2 \times n}$, $T_3 \in \mathbb{R}^{t_3 \times n}, t_1 = t_2 = t_3 = \mathrm{poly}(s_1 s_2 s_3 / \epsilon)$. Notice that

$$\begin{aligned}
&\min_{X_1, X_2, X_3} \left\| \sum_{i=1}^{s_1 s_2 s_3} (T_1 U X_1)_i \otimes (T_2 V X_2)_i \otimes (T_3 W X_3)_i - A(T_1, T_2, T_3) \right\|_F^2 \\
= &\min_{\alpha \in \mathbb{R}^{s_1 \times s_2 \times s_3}} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} \alpha_{i,j,l} \cdot (T_1 U)_i \otimes (T_2 V)_j \otimes (T_3 W)_l - A(T_1, T_2, T_3) \right\|_F^2 .
\end{aligned}$$

Let

$$\alpha' = \arg\min_{\alpha \in \mathbb{R}^{s_1 \times s_2 \times s_3}} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} \alpha_{i,j,l} \cdot (T_1 U)_i \otimes (T_2 V)_j \otimes (T_3 W)_l - A(T_1, T_2, T_3) \right\|_F^2 ,$$

then we have

$$\begin{aligned}
&\left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} \alpha'_{i,j,l} \cdot U_i \otimes V_j \otimes W_l - A \right\|_F^2 \\
\leq &(1+\epsilon) \min_{\alpha \in \mathbb{R}^{s_1 \times s_2 \times s_3}} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} \alpha_{i,j,l} \cdot U_i \otimes V_j \otimes W_l - A \right\|_F^2 .
\end{aligned}$$

Again, according to Lemma 21.4.3, the total running time is then $O(\text{nnz}(A)+n\,\text{poly}(s_1,s_2,s_3,1/\epsilon))$.

□

Lemma 21.4.6. *Given tensor $A \in \mathbb{R}^{n\times n\times n}$, and two matrices $U \in \mathbb{R}^{n\times s}, V \in \mathbb{R}^{n\times s}$ with $\text{rank}(U) = r_1, \text{rank}(V) = r_2$, let $T_1 \in \mathbb{R}^{t_1\times n}, T_2 \in \mathbb{R}^{t_2\times n}$ be two sparse embedding matrices (Definition 21.3.10) with $t_1 = \text{poly}(r_1/\epsilon), t_2 = \text{poly}(r_2/\epsilon)$. Then with probability at least 0.99, $\forall X \in \mathbb{R}^{n\times s}$,*

$$(1-\epsilon)\|U\otimes V\otimes X - A\|_F^2 \leq \|T_1U\otimes T_2V\otimes X - A(T_1,T_2,I)\|_F^2 \leq (1+\epsilon)\|U\otimes V\otimes X - A\|_F^2.$$

Proof. Let $X \in \mathbb{R}^{n\times s}$. We define $Z_1 = (V^\top \odot X^\top) \in \mathbb{R}^{s\times n^2}$. We choose a sparse embedding matrix (Definition 21.3.10) $T_1 \in \mathbb{R}^{t_1\times n}$ with $t_1 = \text{poly}(r_1/\epsilon)$ rows. According to Lemma 21.3.7 with probability 0.999, for all $Z \in \mathbb{R}^{s\times n^2}$,

$$(1-\epsilon)\|UZ - A_1\|_F^2 \leq \|T_1UZ - T_1A_1\|_F^2 \leq (1+\epsilon)\|T_1UZ - A_1\|_F^2.$$

It means that

$$(1-\epsilon)\|UZ_1 - A_1\|_F^2 \leq \|T_1UZ_1 - T_1A_1\|_F^2 \leq (1+\epsilon)\|T_1UZ_1 - A_1\|_F^2.$$

Second, we unflatten matrix $T_1A_1 \in \mathbb{R}^{t_1\times n^2}$ to obtain a tensor $A' \in \mathbb{R}^{t_1\times n\times n}$. Then we flatten A' along the second direction to obtain $A'_2 \in \mathbb{R}^{n\times t_1 n}$. We define $Z_2 = ((T_1U)^\top \odot X^\top) \in \mathbb{R}^{s\times t_1 n}$. Then, by flattening,

$$\|V\cdot Z_2 - A'_2\|_F^2 = \|T_1U\cdot Z_1 - T_1A_1\|_F^2 = (1\pm\epsilon)\|U\otimes V\otimes X - A\|_F^2.$$

We choose a sparse embedding matrix (Definition 21.3.10) $T_2 \in \mathbb{R}^{t_2\times n}$ with $t_2 = \text{poly}(r_2/\epsilon)$ rows. Then according to Lemma 21.3.7 with probability 0.999, for all $Z \in \mathbb{R}^{s\times t_1 n}$,

$$(1-\epsilon)\|VZ - A'_2\|_F^2 \leq \|T_2VZ - T_2A'_2\|_F^2 \leq (1+\epsilon)\|VZ - A'_2\|_F^2.$$

Thus,

$$\|T_2V \cdot Z_2 - T_2A_2'\|_F^2 = (1 \pm \epsilon)^2\|U \otimes V \otimes X - A\|_F^2.$$

After rescaling ϵ by a constant, with probability at least 0.99, $\forall X \in \mathbb{R}^{n \times s}$,

$$(1-\epsilon)\|U \otimes V \otimes X - A\|_F^2 \leq \|T_1U \otimes T_2V \otimes X - A(T_1, T_2, I)\|_F^2 \leq (1+\epsilon)\|U \otimes V \otimes X - A\|_F^2.$$

□

21.4.4.2 Algorithm I

We start with a slightly unoptimized bicriteria low rank approximation algorithm.

Algorithm 21.5 Frobenius Norm Bicriteria Low Rank Approximation Algorithm, rank-$O(k^3/\epsilon^3)$

procedure FTensorLowRankBicriteriaCubicRank(A, n, k) ▷ Theorem 21.4.7
  $s_1 \leftarrow s_2 \leftarrow s_3 \leftarrow O(k/\epsilon)$.
  $t_1 \leftarrow t_2 \leftarrow t_3 \leftarrow \text{poly}(k/\epsilon)$.
  Choose $S_i \in \mathbb{R}^{n^2 \times s_i}$ to be a Sketching matrix, $\forall i \in [3]$. ▷ Definition 21.3.12
  Choose $T_i \in \mathbb{R}^{t_i \times n}$ to be a Sketching matrix, $\forall i \in [3]$. ▷ Definition 21.3.10
  Compute $U \leftarrow T_1 \cdot (A_1 \cdot S_1)$, $V \leftarrow T_2 \cdot (A_2 \cdot S_2)$, $W \leftarrow T_3 \cdot (A_3 \cdot S_3)$.
  Compute $C \leftarrow A(T_1, T_2, T_3)$.
  $X \leftarrow$FTensorRegression$(C, U, V, W, t_1, s_1, t_2, s_2, t_3, s_3)$. ▷ Linear regression
  return $X(A_1S_1, A_2S_2, A_3S_3)$.
end procedure

Theorem 21.4.7. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1, \epsilon \in (0,1)$, let $r = O(k^3/\epsilon^3)$. There exists an algorithm that takes $O(\text{nnz}(A) + n\,\text{poly}(k, 1/\epsilon))$ time and outputs three matrices $U \in \mathbb{R}^{n \times r}, V \in \mathbb{R}^{n \times r}$, $W \in \mathbb{R}^{n \times r}$ such that*

$$\left\| \sum_{i=1}^{r} U_i \otimes V_i \otimes W_i - A \right\|_F^2 \leq (1+\epsilon) \min_{\text{rank}-k\ A_k} \|A_k - A\|_F^2$$

holds with probability 9/10.

Proof. At the end of Theorem 21.4.1, we need to run a polynomial system verifier. This is why we obtain exponential in k running time. Instead of running the polynomial system verifier, we can use Lemma 21.4.5. This reduces the running time to be polynomial in all parameters: $n, k, 1/\epsilon$. However, the output tensor has rank $(k/\epsilon)^3$ (Here we mean that we do not obtain a better decomposition than $(k/\epsilon)^3$ components). According to Section 21.3.6, for each i, $A_i S_i$ can be computed in $O(\mathrm{nnz}(A)) + n\,\mathrm{poly}(k/\epsilon)$ time. Then $T_i(A_i S_i)$ can be computed in $n\,\mathrm{poly}(k, 1/\epsilon)$ time and $A(T_1, T_2, T_3)$ also can be computed in $O(\mathrm{nnz}(A))$ time. The running time for the regression is $\mathrm{poly}(k/\epsilon)$. □

Now we present an optimized bicriteria algorithm.

Theorem 21.4.8. *Given a 3rd order tensor $A \in \mathbb{R}^{n\times n\times n}$, for any $k \geq 1, \epsilon \in (0,1)$, let $r = O(k^2/\epsilon^2)$. There exists an algorithm that takes $O(\mathrm{nnz}(A) + n\,\mathrm{poly}(k, 1/\epsilon))$ time and outputs three matrices $U \in \mathbb{R}^{n\times r}, V \in \mathbb{R}^{n\times r}$, $W \in \mathbb{R}^{n\times r}$ such that*

$$\left\| \sum_{i=1}^{r} U_i \otimes V_i \otimes W_i - A \right\|_F^2 \leq (1+\epsilon) \min_{\mathrm{rank}-k\ A_k} \|A_k - A\|_F^2$$

holds with probability 9/10.

Note that there are two different ways to implement algorithm FTensorLowRankBicriteriaQuadraticRank. We present the proofs for both of them here.

Approach I.

Proof. Let $\mathrm{OPT} = \min_{\mathrm{rank}-k\ A_k} \|A_k - A\|_F^2$. According to Theorem 21.4.1, we know that there exists a sketching matrix $S_3 \in \mathbb{R}^{n^2\times s_3}$ where $s_3 = O(k/\epsilon)$, such that

$$\min_{X_1\in\mathbb{R}^{s_1\times k}, X_2\in\mathbb{R}^{s_2\times k}, X_3\in\mathbb{R}^{s_3\times k}} \left\| \sum_{l=1}^{k} (A_1 S_1 X_1)_l \otimes (A_2 S_2 X_2)_l \otimes (A_3 S_3 X_3)_l - A \right\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}$$

Algorithm 21.6 Frobenius Norm Low Rank Approximation Algorithm, rank-$O(k^2/\epsilon^2)$

procedure FTensorLowRankBicriteriaQuadraticRank(A, n, k) ▷ Theorem 21.4.8
  $s_1 \leftarrow s_2 \leftarrow O(k/\epsilon)$.
  Choose $S_i \in \mathbb{R}^{n^2 \times s_i}$ to be a sketching matrix, $\forall i \in [3]$. ▷ Definition 21.3.12
  Compute $A_1 \cdot S_1$, $A_2 \cdot S_2$.
  Form $\widehat{U}$ by using $A_1 S_1$ according to Equation (21.9).
  Form $\widehat{V}$ by using $A_2 S_2$ according to Equation (21.10).
  $\widehat{W} \leftarrow$FTensorMultipleRegression$(A, \widehat{U}, \widehat{V}, n, n, s_1 s_2)$. ▷ Algorithm 21.4
  return $\widehat{U}, \widehat{V}, \widehat{W}$.
end procedure
procedure FTensorLowRankBicriteriaQuadraticRank(A, n, k) ▷ Theorem 21.4.8
  $s_1 \leftarrow s_2 \leftarrow O(k/\epsilon)$.
  $t_1 \leftarrow t_2 \leftarrow \mathrm{poly}(k/\epsilon)$.
  Choose $S_i \in \mathbb{R}^{n^2 \times s_i}$ to be a Sketching matrix, $\forall i \in [2]$. ▷ Definition 21.3.12
  Choose $T_i \in \mathbb{R}^{t_i \times n}$ to be a Sketching matrix, $\forall i \in [2]$. ▷ Definition 21.3.10
  Form $\widehat{U}$ by using $A_1 S_1$ according to Equation (21.9).
  Form $\widehat{V}$ by using $A_2 S_2$ according to Equation (21.10).
  Compute $C \leftarrow A(T_1, T_2, I)$. ▷ $C \in \mathbb{R}^{t_1 \times t_2 \times n}$
  Compute $B \leftarrow (T_1 \widehat{U})^\top \odot (T_2 \widehat{V})^\top$.
  $\widehat{W} \leftarrow \arg\min_{X \in \mathbb{R}^{n \times s_1 s_2}} \|XB - C_3\|_F^2$.
  return $\widehat{U}, \widehat{V}, \widehat{W}$.
end procedure

Now we fix an l and we have:

$$\begin{aligned}
&(A_1 S_1 X_1)_l \otimes (A_2 S_2 X_2)_l \otimes (A_3 S_3 X_3)_l \\
=&\left(\sum_{i=1}^{s_1} (A_1 S_1)_i (X_1)_{i,l}\right) \otimes \left(\sum_{j=1}^{s_2} (A_2 S_2)_j (X_2)_{j,l}\right) \otimes (A_3 S_3 X_3)_l \\
=&\sum_{i=1}^{s_1} \sum_{j=1}^{s_2} (A_1 S_1)_i \otimes (A_2 S_2)_j \otimes (A_3 S_3 X_3)_l (X_1)_{i,l} (X_2)_{j,l}
\end{aligned}$$

Thus, we have

$$\min_{X_1,X_2,X_3} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} (A_1S_1)_i \otimes (A_2S_2)_j \otimes \left(\sum_{l=1}^{k} (A_3S_3X_3)_l (X_1)_{i,l} (X_2)_{j,l} \right) - A \right\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}\,. \tag{21.7}$$

We use matrices $A_1S_1 \in \mathbb{R}^{n\times s_1}$ and $A_2S_2 \in \mathbb{R}^{n\times s_2}$ to construct a matrix $B \in \mathbb{R}^{s_1s_2\times n^2}$ in the following way: each row of B is the vector corresponding to the matrix generated by the $\otimes$ product between one column vector in A_1S_1 and the other column vector in A_2S_2, i.e.,

$$B^{i+(j-1)s_1} = \mathrm{vec}((A_1S_1)_i \otimes (A_2S_2)_j), \forall i \in [s_1], j \in [s_2], \tag{21.8}$$

where $(A_1S_1)_i$ denotes the i-th column of A_1S_1 and $(A_2S_2)_j$ denote the j-th column of A_2S_2.

We create matrix $\widehat{U} \in \mathbb{R}^{n\times s_1s_2}$ by copying matrix A_1S_1 s_2 times, i.e.,

$$\widehat{U} = \begin{bmatrix} A_1S_1 & A_1S_1 & \cdots & A_1S_1 \end{bmatrix}. \tag{21.9}$$

We create matrix $\widehat{V} \in \mathbb{R}^{n\times s_1s_2}$ by copying the i-th column of A_2S_2 a total of s_1 times, into columns $(i-1)s_1, \cdots, is_1$ of $\widehat{V}$, for each $i \in [s_2]$, i.e.,

$$\widehat{V} = \begin{bmatrix} (A_2S_2)_1 & \cdots & (A_2S_2)_1 & (A_2S_2)_2 & \cdots & (A_2S_2)_2 & \cdots & (A_2S_2)_{s_2} & \cdots & (A_2S_2)_{s_2} \end{bmatrix}. \tag{21.10}$$

Thus, we can use $\widehat{U}$ and $\widehat{V}$ to represent B,

$$B = (\widehat{U}^\top \odot \widehat{V}^\top) \in \mathbb{R}^{s_1s_2\times n^2}.$$

According to Equation (21.7), we have:

$$\min_{W\in\mathbb{R}^{n\times s_1s_2}} \|WB - A_3\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}\,.$$

Next, we want to find matrix $W \in \mathbb{R}^{n \times s_1 s_2}$ by solving the following optimization problem,

$$\min_{W \in \mathbb{R}^{n \times s_1 s_2}} \|WB - A_3\|_F^2.$$

Note that B has size $s_1 s_2 \times n^2$. Naïvely writing down B already requires $\Omega(n^2)$ time. In order to achieve nearly linear time in n, we cannot write down B. We choose $S_3 \in \mathbb{R}^{n_1 n_2 \times s_3}$ to be a TensorSketch (Definition 21.3.20). In order to solve multiple regression, we need to set $s_3 = O((s_1 s_2)^2 + (s_1 s_2)/\epsilon)$. Let $\widehat{W}$ denote the optimal solution to $\|WBS_3 - A_3 S_3\|_F^2$. Then $\widehat{W} = (A_3 S_3)(BS_3)^\dagger$. Since each row of S_3 has exactly 1 nonzero entry, $A_3 S_3$ can be computed in $O(\mathrm{nnz}(A))$ time. Since $B = (\widehat{U}^\top \odot \widehat{V}^\top)$, according to Definition 21.3.20, BS_3 can be computed in $n \,\mathrm{poly}(s_1 s_2/\epsilon) = n \,\mathrm{poly}(k/\epsilon)$ time. By Theorem 21.4.4, we have

$$\|\widehat{W}B - A_3\|_F^2 \leq (1+\epsilon) \min_{W \in \mathbb{R}^{n \times s_1 s_2}} \|WB - A_3\|_F^2.$$

Thus, we have

$$\|\widehat{U} \otimes \widehat{V} \otimes \widehat{W} - A\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}\,.$$

According to Definition 21.3.12, $A_1 S_1, A_2 S_2$ can be computed in $O(\mathrm{nnz}(A) + \mathrm{poly}(k/\epsilon))$ time. Te total running time is thus $O(\mathrm{nnz}(A) + \mathrm{poly}(k/\epsilon))$. □

Approach II.

Proof. Let $\mathrm{OPT} = \min_{\mathrm{rank}-k\ A_k} \|A_k - A\|_F^2$. Choose sketching matrices (Definition 21.3.12) $S_1 \in \mathbb{R}^{n^2 \times s_1}$, $S_2 \in \mathbb{R}^{n^2 \times s_2}$, $S_3 \in \mathbb{R}^{n^2 \times s_3}$, and sketching matrices (Definition 21.3.10) $T_1 \in \mathbb{R}^{t_1 \times n}$ and

$T_2 \in \mathbb{R}^{t_2 \times n}$ with $s_1 = s_2 = s_3 = O(k/\epsilon), t_1 = t_2 = \mathrm{poly}(k/\epsilon)$. We create matrix $\widehat{U} \in \mathbb{R}^{n \times s_1 s_2}$ by copying matrix $A_1 S_1$ s_2 times, i.e.,

$$\widehat{U} = \begin{bmatrix} A_1 S_1 & A_1 S_1 & \cdots & A_1 S_1 \end{bmatrix}.$$

We create matrix $\widehat{V} \in \mathbb{R}^{n \times s_1 s_2}$ by copying the i-th column of $A_2 S_2$ a total of s_1 times, into columns $(i-1)s_1, \cdots, is_1$ of $\widehat{V}$, for each $i \in [s_2]$, i.e.,

$$\widehat{V} = \begin{bmatrix} (A_2 S_2)_1 & \cdots & (A_2 S_2)_1 & (A_2 S_2)_2 & \cdots & (A_2 S_2)_2 & \cdots & (A_2 S_2)_{s_2} & \cdots & (A_2 S_2)_{s_2} \end{bmatrix}.$$

As we proved in Approach I, we have

$$\min_{X \in \mathbb{R}^{n \times s_1 s_2}} \|\widehat{U} \otimes \widehat{V} \otimes X - A\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}\,.$$

Let $B = ((T_1 \widehat{U})^\top \odot (T_2 \widehat{V})^\top) \in \mathbb{R}^{s_1 s_2 \times t_1 t_2}$, and flatten $A(T_1, T_2, I)$ along the third direction to obtain $C_3 \in \mathbb{R}^{n \times t_1 t_2}$. Let

$$\widehat{W} = \arg\min_{X \in \mathbb{R}^{n \times s_1 s_2}} \|T_1 \widehat{U} \otimes T_2 \widehat{V} \otimes X - A(T_1, T_2, I)\|_F^2 = \arg\min_{X \in \mathbb{R}^{n \times s_1 s_2}} \|XB - C_3\|_F^2.$$

Let

$$W^* = \arg\min_{X \in \mathbb{R}^{n \times s_1 s_2}} \|\widehat{U} \otimes \widehat{V} \otimes X - A\|_F^2.$$

According to Lemma 21.4.6,

$$\begin{aligned}
& \|\widehat{U} \otimes \widehat{V} \otimes \widehat{W} - A\|_F^2 \\
\leq & \frac{1}{1-\epsilon} \|T_1 \widehat{U} \otimes T_2 \widehat{V} \otimes \widehat{W} - A(T_1, T_2, I)\|_F^2 \\
\leq & \frac{1}{1-\epsilon} \|T_1 \widehat{U} \otimes T_2 \widehat{V} \otimes W^* - A(T_1, T_2, I)\|_F^2 \\
\leq & \frac{1+\epsilon}{1-\epsilon} \|\widehat{U} \otimes \widehat{V} \otimes W^* - A\|_F^2 \\
\leq & \frac{(1+\epsilon)^2}{1-\epsilon}\,\mathrm{OPT}\,.
\end{aligned}$$

According to Definition 21.3.12, A_1S_1, A_2S_2 can be computed in $O(\text{nnz}(A)+\text{poly}(k/\epsilon))$ time. The total running time is thus $O(\text{nnz}(A)+\text{poly}(k/\epsilon))$. Since T_1, T_2 are sparse embedding matrices, $T_1\widehat{U}, T_2\widehat{V}$ can be computed in $O(\text{nnz}(A)+\text{poly}(k/\epsilon))$ time. The total running time is in $O(\text{nnz}(A)+\text{poly}(k/\epsilon))$. □

Theorem 21.4.9. *Given a 3rd order tensor $A \in \mathbb{R}^{n\times n\times n}$, for any $k \geq 1$ and any $0 < \epsilon < 1$, if A_k exists then there is a randomized algorithm running in $\text{nnz}(A) + n \cdot \text{poly}(k/\epsilon)$ time which outputs a rank-$O(k^2/\epsilon^2)$ tensor B for which $\|A - B\|_F^2 \leq (1+\epsilon)\|A - A_k\|_F^2$. If A_k does not exist, then the algorithm outputs a rank-$O(k^2/\epsilon^2)$ tensor B for which $\|A - B\|_F^2 \leq (1+\epsilon)\,\text{OPT} + \gamma$, where γ is an arbitrarily small positive function of n. In both cases, the algorithm succeeds with probability at least $9/10$.*

Proof. If A_k exists, then the proof directly follows the proof of Theorem 21.4.1 and Theorem 21.4.8. If A_k does not exist, then for any $\gamma > 0$, there exist $U^* \in \mathbb{R}^{n\times k}, V^* \in \mathbb{R}^{n\times k}, W^* \in \mathbb{R}^{n\times k}$ such that

$$\|U^* \otimes V^* \otimes W^* - A\|_F^2 \leq \inf_{\text{rank}-k\ A'} \|A - A'\|_F^2 + \frac{1}{10}\gamma.$$

Then we just regard $U^* \otimes V^* \otimes W^*$ as the "best" rank k approximation to A, and follow the same argument as in the proof of Theorem 21.4.1 and the proof of Theorem 21.4.8. We can finally output a tensor $B \in \mathbb{R}^{n\times n\times n}$ with rank-$O(k^2/\epsilon^2)$ such that

$$\begin{aligned}
\|B - A\|_F^2 \leq\ & (1+\epsilon)\|U^* \otimes V^* \otimes W^* - A\|_F^2 \\
\leq\ & (1+\epsilon)\left(\inf_{\text{rank}-k\ A'} \|A - A'\|_F^2 + \frac{1}{10}\gamma\right) \\
\leq\ & (1+\epsilon)\inf_{\text{rank}-k\ A'} \|A - A'\|_F^2 + \gamma
\end{aligned}$$

where the first inequality follows by the proof of Theorem 21.4.1 and the proof of theorem 21.4.8. The second inequality follows by our choice of U^*, V^*, W^*. The third inequality follows since $1 + \epsilon < 2$ and $\gamma > 0$. □

21.4.4.3 poly(k)-approximation to multiple regression

Lemma 21.4.10 ((1.4) and (1.9) in [RV09]). *Let $s \geq k$. Let $U \in \mathbb{R}^{n \times k}$ denote a matrix that has orthonormal columns, and $S \in \mathbb{R}^{s \times n}$ denote an i.i.d. $N(0, 1/s)$ Gaussian matrix. Then SU is also an $s \times k$ i.i.d. Gaussian matrix with each entry draw from $N(0, 1/s)$, and furthermore, we have with arbitrarily large constant probability,*

$$\sigma_{\max}(SU) = O(1) \text{ and } \sigma_{\min}(SU) = \Omega(1/\sqrt{s}).$$

Proof. Note that $\sqrt{s} - \sqrt{k-1} = \frac{s-k-1}{\sqrt{s}+\sqrt{k-1}} = \Omega(1/\sqrt{s})$. □

Lemma 21.4.11. *Given matrices $A \in \mathbb{R}^{n \times k}$, $B \in \mathbb{R}^{n \times d}$, let $S \in \mathbb{R}^{s \times n}$ denote a standard Gaussian $N(0, 1)$ matrix with $s = k$. Let $X^* = \min_{X \in \mathbb{R}^{k \times d}} \|AX - B\|_F$. Let $X' = \min_{X \in \mathbb{R}^{k \times d}} \|SAX - SB\|_F$. Then, we have that*

$$\|AX' - B\|_F \leq O(\sqrt{k}) \|AX^* - B\|_F,$$

holds with probability at least 0.99.

Proof. Let $X^* \in \mathbb{R}^{k \times d}$ denote the optimal solution such that

$$\|AX^* - B\|_F = \min_{X \in \mathbb{R}^{k \times d}} \|AX - B\|_F.$$

Consider a standard Gaussian matrix $S \in \mathbb{R}^{k \times n}$ scaled by $1/\sqrt{k}$ with exactly k rows. Then for any $X \in \mathbb{R}^{k \times d}$, by the triangle inequality, we have

$$\|SAX - SB\|_F \leq \|SAX - SAX^*\|_F + \|SAX^* - SB\|_F,$$

and

$$\|SAX - SB\|_F \geq \|SAX - SAX^*\|_F - \|SAX^* - SB\|_F.$$

We first show how to bound $\|SAX - SAX^*\|_F$, and then show how to bound $\|SAX^* - SB\|_F$.

Note that Lemma 21.4.10 implies the following result,

Claim 21.4.12. *For any $X \in \mathbb{R}^{k \times d}$, with probability 0.999, we have*

$$\frac{1}{\sqrt{k}}\|AX - AX^*\|_F \lesssim \|SAX - SAX^*\|_F \lesssim \|AX - AX^*\|_F.$$

Proof. First, we can write $A = UR \in \mathbb{R}^{n \times k}$ where $U \in \mathbb{R}^{n \times k}$ has orthonormal columns and $R \in \mathbb{R}^{k \times k}$. It gives,

$$\|SAX - SAX^*\|_F = \|SU(RX - RX^*)\|_F.$$

Second, applying Lemma 21.4.10 to $SU \in \mathbb{R}^{s \times k}$ completes the proof. □

Using Markov's inequality, for any fixed matrix $AX^* - B$, choosing a Gaussian matrix S, we have that

$$\|SAX^* - SB\|_F^2 = O(\|AX^* - B\|_F^2)$$

holds with probability at least 0.999. This is equivalent to

$$\|SAX^* - SB\|_F = O(\|AX^* - B\|_F), \tag{21.11}$$

holding with probability at least 0.999.

Let $X' = \arg\min_{X \in \mathbb{R}^{k \times d}} \|SAX - SB\|_F$. Putting it all together, we have

$$\begin{aligned}
&\|AX' - B\|_F \\
\leq\ & \|AX' - AX^*\|_F + \|AX^* - B\|_F && \text{by triangle inequality} \\
\leq\ & O(\sqrt{k})\|SAX' - SAX^*\|_F + \|AX^* - B\|_F && \text{by Claim 21.4.12} \\
\leq\ & O(\sqrt{k})\|SAX' - SB\|_F + O(\sqrt{k})\|SAX^* - SB\|_F + \|AX^* - B\|_F && \text{by triangle inequality} \\
\leq\ & O(\sqrt{k})\|SAX^* - SB\|_F + O(\sqrt{k})\|SAX^* - SB\|_F + \|AX^* - B\|_F && \text{by definition of } X' \\
\leq\ & O(\sqrt{k})\|AX^* - B\|_F. && \text{by Equation (21.11)}
\end{aligned}$$

□

21.4.4.4 Algorithm II

Theorem 21.4.13. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$, let $r = k^2$. There exists an algorithm which takes $O(\mathrm{nnz}(A)k) + n\,\mathrm{poly}(k)$ time and outputs three matrices $U, V, W \in \mathbb{R}^{n \times r}$ such that,*

$$\left\| \sum_{i=1}^{r} U_i \otimes V_i \otimes W_i - A \right\|_F \leq \mathrm{poly}(k) \min_{\mathrm{rank}-k\ A'} \|A' - A\|_F$$

holds with probability 9/10.

Proof. Let $\mathrm{OPT} = \min_{\mathrm{rank}-k\ A'} \|A' - A\|_F$, we fix $V^* \in \mathbb{R}^{n \times k}, W^* \in \mathbb{R}^{n \times k}$ to be the optimal solution of the original problem. We use $Z_1 = (V^{*\top} \odot W^{*\top}) \in \mathbb{R}^{k \times n^2}$ to denote the matrix where the i-th row is the vectorization of $V_i^* \otimes W_i^*$. Let $A_1 \in \mathbb{R}^{n \times n^2}$ denote the matrix

obtained by flattening tensor $A \in \mathbb{R}^{n \times n \times n}$ along the first direction. Then, we have

$$\min_U \|UZ_1 - A_1\|_F \leq \mathrm{OPT}\,.$$

Choosing an $N(0, 1/k)$ Gaussian sketching matrix $S_1 \in \mathbb{R}^{n^2 \times s_1}$ with $s_1 = k$, we can obtain the smaller problem,

$$\min_{U \in \mathbb{R}^{n \times k}} \|UZ_1S_1 - A_1S_1\|_F.$$

Define $\widehat{U} = A_1S_1(Z_1S_1)^\dagger$. Define $\alpha = O(\sqrt{k})$. By Lemma 21.4.11, we have

$$\|\widehat{U}Z_1 - A_1\|_F \leq \alpha\,\mathrm{OPT}\,.$$

Second, we fix $\widehat{U}$ and W^*. Define Z_2, A_2 similarly as above. Choosing an $N(0, 1/k)$ Gaussian sketching matrix $S_2 \in \mathbb{R}^{n^2 \times s_2}$ with $s_2 = k$, we can obtain another smaller problem,

$$\min_{V \in \mathbb{R}^{n \times k}} \|VZ_2S_2 - A_2S_2\|_F.$$

Define $\widehat{V} = A_2S_2(Z_2S_2)^\dagger$. By Lemma 21.4.11 again, we have

$$\|\widehat{V}Z_2 - A_2\|_F \leq \alpha^2\,\mathrm{OPT}\,.$$

Thus, we now have

$$\min_{X_1, X_2, W} \|A_1S_1X_1 \otimes A_2S_2X_2 \otimes W - A\|_F \leq \alpha^2\,\mathrm{OPT}$$

We use a similar idea as in the proof of Theorem 21.4.8. We create matrix $\widetilde{U} \in \mathbb{R}^{n \times s_1s_2}$ by copying matrix A_1S_1 s_2 times, i.e.,

$$\widetilde{U} = \begin{bmatrix} A_1S_1 & A_1S_1 & \cdots & A_1S_1 \end{bmatrix}.$$

We create matrix $\widetilde{V} \in \mathbb{R}^{n \times s_1 s_2}$ by copying the i-th column of $A_2 S_2$ a total of s_1 times, into columns $(i-1)s_1, \cdots, is_1$ of $\widetilde{V}$, for each $i \in [s_2]$, i.e.,

$$\widetilde{V} = \begin{bmatrix} (A_2S_2)_1 & \cdots & (A_2S_2)_1 & (A_2S_2)_2 & \cdots & (A_2S_2)_2 & \cdots & (A_2S_2)_{s_2} & \cdots & (A_2S_2)_{s_2} \end{bmatrix}.$$

We have

$$\min_{X \in \mathbb{R}^{n \times s_1 s_2}} \|\widetilde{U} \otimes \widetilde{V} \otimes X - A\|_F \leq \alpha^2 \operatorname{OPT}.$$

Choose $T_i \in \mathbb{R}^{t_i \times n}$ to be a sparse embedding matrix (Definition 21.3.10) with $t_i = \operatorname{poly}(k/\epsilon)$, for each $i \in [2]$. By applying Lemma 21.4.6, we have, if W' satisfies,

$$\|T_1\widetilde{U} \otimes T_2\widetilde{V} \otimes W' - A(T_1, T_2, I)\|_F = \min_{X \in \mathbb{R}^{n \times s_1 s_2}} \|T_1\widetilde{U} \otimes T_2\widetilde{V} \otimes X - A(T_1, T_2, I)\|_F$$

then,

$$\|\widetilde{U} \otimes \widetilde{V} \otimes W' - A\|_F \leq (1+\epsilon) \min_{X \in \mathbb{R}^{n \times s_1 s_2}} \|\widetilde{U} \otimes \widetilde{V} \otimes X - A\|_F \leq (1+\epsilon)\alpha^2 \operatorname{OPT}.$$

Thus, we only need to solve

$$\min_{X \in \mathbb{R}^{n \times s_1 s_2}} \|T_1\widetilde{U} \otimes T_2\widetilde{V} \otimes X - A(T_1, T_2, I)\|_F.$$

which is similar to the proof of Theorem 21.4.8. Therefore, we complete the proof of correctness. For the running time, A_1S_1, A_2S_2 can be computed in $O(\operatorname{nnz}(A)k)$ time, $T_1\widetilde{U}, T_2\widetilde{V}$ can be computed in $n \operatorname{poly}(k)$ time. The final regression problem can be computed in $n \operatorname{poly}(k)$ running time. □

21.4.5 Generalized matrix row subset selection

Note that in this section, the notation $\Pi_{C,k}^{\xi}$ is given in Definition 21.3.5.

Algorithm 21.7 Generalized Matrix Row Subset Selection: Constructing R with $r = O(k + k/\epsilon)$ Rows and a rank-k $U \in \mathbb{R}^{k \times r}$

  return R, U.
end procedure

Theorem 21.4.14. *Given matrices $A \in \mathbb{R}^{n \times m}$ and $C \in \mathbb{R}^{n \times k}$, there exists an algorithm which takes $O(\mathrm{nnz}(A) \log n) + (m+n)\,\mathrm{poly}(k, 1/\epsilon)$ time and outputs a diagonal matrix $D \in \mathbb{R}^{n \times n}$ with $d = O(k/\epsilon)$ nonzeros (or equivalently a matrix R that contains $d = O(k/\epsilon)$ rescaled*

rows of A) and a matrix $U \in \mathbb{R}^{k\times d}$ such that

$$\|CUDA - A\|_F^2 \leq (1+\epsilon) \min_{X\in\mathbb{R}^{k\times m}} \|CX - A\|_F^2$$

holds with probability .99.

Proof. This follows by combining Lemma 21.4.17 and 21.4.18. Let U, R denote the output of procedure GeneralizedMatrixRowSubsetSelection,

$$\begin{aligned}\|A - CUR\|_F^2 &\leq (1+\epsilon)\|A - Z_2 Z_2^\top A R^\dagger R\|_F^2 \\ &\leq (1+\epsilon)(1+60\epsilon)\|A - \Pi_{C,k}^F(A)\|_F^2 \\ &\leq (1+130\epsilon)\|A - \Pi_{C,k}^F(A)\|_F^2.\end{aligned}$$

Because R is a subset of rows of A and R has size $O(k/\epsilon) \times m$, there must exist a diagonal matrix $D \in \mathbb{R}^{n\times n}$ with $O(k/\epsilon)$ nonzeros such that $R = DA$. This completes the proof. □

Corollary 21.4.15 (A slightly different version of Theorem 21.4.14, faster running time, and small input matrix)**.** *Given matrices $A \in \mathbb{R}^{n\times m}$ and $C \in \mathbb{R}^{n\times k}$, if $\min(m,n) = \mathrm{poly}(k, 1/\epsilon)$, then there exists an algorithm which takes $O(\mathrm{nnz}(A)) + (m+n)\,\mathrm{poly}(k, 1/\epsilon)$ time and outputs a diagonal matrix $D \in \mathbb{R}^{n\times n}$ with $d = O(k/\epsilon)$ nonzeros (or equivalently a matrix R that contains $d = O(k/\epsilon)$ rescaled rows of A) and a matrix $U \in \mathbb{R}^{k\times d}$ such that*

$$\|CUDA - A\|_F^2 \leq (1+\epsilon) \min_{X\in\mathbb{R}^{k\times m}} \|CX - A\|_F^2$$

holds with probability .99.

Proof. The $\log n$ factor comes from the adaptive sampling where we need to choose a Gaussian matrix with $O(\log n)$ rows and compute SA. If A has $\mathrm{poly}(k, 1/\epsilon)$ columns, it is sufficient

to choose S to be a CountSketch matrix with $\text{poly}(k, 1/\epsilon)$ rows. Then, we do not need a $\log n$ factor in the running time. If S has $\text{poly}(k, 1/\epsilon)$ rows, then we no longer need the matrix S. □

Claim 21.4.16. *Given matrices $A \in \mathbb{R}^{m\times n}$ and $C \in \mathbb{R}^{m\times c}$, let $Y \in \mathbb{R}^{m\times c}, \Phi \in \mathbb{R}^{c\times c}$ and $\Delta \in \mathbb{R}^{c\times k}$ denote the output of procedure* ApproxSubspaceSVD(A, C, k, ϵ). *Then with probability .99, we have,*

$$\|A - Y\Delta\Delta^\top Y^\top A\|_F^2 \leq (1 + 30\epsilon)\|A - \Pi_{C,k}^F(A)\|_F^2.$$

Proof. This follows by Lemma 3.12 in [BW14]. □

Lemma 21.4.17. *The matrices R and Z_2 in procedure* GeneralizedMatrixRowSubsetSelection *(Algorithm 21.7) satisfy with probability at least $0.17 - 2/n$,*

$$\|A - Z_2 Z_2^\top A R^\dagger R\|_F^2 \leq \|A - \Pi_{C,k}^F(A)\|_F^2 + 60\epsilon\|A - \Pi_{C,k}^F(A)\|_F^2.$$

Proof. We can show,

$$\begin{aligned}
&\|A - Z_2 Z_2^\top A\|_F^2 + \frac{30\epsilon}{4820}\|A - AR_1^\dagger R_1\|_F^2 \\
=\ &\|A - BB^\dagger A\|_F^2 + \frac{30\epsilon}{4820}\|A - AR_1^\dagger R_1\|_F^2 \\
\leq\ &\|A - BB^\dagger A\|_F^2 + 30\epsilon\|A - A_k\|_F^2 \\
\leq\ &\|A - Y\Delta\Delta^\top Y A\|_F^2 + 30\epsilon\|A - \Pi_{C,k}^F(A)\|_F^2 \\
\leq\ &(1 + 30\epsilon)\|A - \Pi_{C,k}^F(A)\|_F^2 + 30\epsilon\|A - \Pi_{C,k}^F(A)\|_F^2,
\end{aligned}$$

where the first step follows by the fact that $Z_2 Z_2^\top = Z_2 D D^{-1} Z_2^\top = (Z_2 D)(Z_2 D)^\dagger = BB^\dagger$, the second step follows by $\|A - AR_1^\dagger R_1\|_F^2 \leq 4820\|A - A_k\|_F^2$, the third step follows by $B = Y\Delta$ and $B^\dagger = (Y\Delta)^\dagger = \Delta^\dagger Y^\dagger = \Delta^\top Y^\top$, and the last step follows by Claim 21.4.16. □

Lemma 21.4.18. *The matrices C, U and R in procedure* GeneralizedMatrixRowSubsetSelection *(Algorithm 21.7) satisfy that*

$$\|A - CUR\|_F^2 \leq (1+\epsilon)\|A - Z_2 Z_2^\top A R^\dagger R\|_F^2$$

with probability at least .99.

Proof. Let U_R, Σ_R, V_R denote the SVD of R. Then $V_R V_R^\top = R^\dagger R$.

We define Y^* to be the optimal solution of

$$\min_{X \in \mathbb{R}^{k \times r}} \|WAV_R V_R^\top - WC\Phi^{-1}\Delta D^{-1} Y R\|_F^2.$$

We define $\widehat{X}^*$ to be $Y^* R \in \mathbb{R}^{k \times n}$, which is also equivalent to defining $\widehat{X}^*$ to be the optimal solution of

$$\min_{X \in \mathbb{R}^{k \times n}} \|WAV_R V_R^\top - WC\Phi^{-1}\Delta D^{-1} X\|_F^2.$$

Furthermore, it implies $\widehat{X}^* = (WC\Phi^{-1}\Delta D^{-1})^\dagger WAV_R V_R^\dagger$.

We also define X^* to be the optimal solution of

$$\min_{X \in \mathbb{R}^{k \times n}} \|AV_R V_R^\dagger - C\Phi^{-1}\Delta D^{-1} X\|_F^2,$$

which implies that,

$$X^* = (C\Phi^{-1}\Delta D^{-1})^\dagger AV_R V_R^\top = Z_2^\top AV_R V_R^\top.$$

Now, we start to prove an upper bound on $\|A - CUR\|_F^2$,

$$\begin{aligned}
\|A - CUR\|_F^2 &= \|A - C\Phi^{-1}\Delta D^{-1}Y^*R\|_F^2 && \text{by definition of } U \\
&= \|A - C\Phi^{-1}\Delta D^{-1}\widehat{X}^*\|_F^2 && \text{by } \widehat{X}^* = Y^*R \\
&= \|AV_RV_R^\top - C\Phi^{-1}\Delta D^{-1}\widehat{X}^* + A - AV_RV_R^\top\|_F^2 \\
&= \underbrace{\|AV_RV_R^\top - C\Phi^{-1}\Delta D^{-1}\widehat{X}^*\|_F^2}_{\alpha} + \underbrace{\|A - AV_RV_R^\top\|_F^2}_{\beta}, && (21.12)
\end{aligned}$$

where the last step follows by $\widehat{X}^* = MV_R^\top$, $A - AV_RV_R^\top = A(I - V_RV_R^\top)$ and the Pythagorean theorem. We show how to upper bound the term α,

$$\begin{aligned}
\alpha &\leq (1+\epsilon)\|AV_RV_R^\top - C\Phi^{-1}\Delta D^{-1}X^*\|_F^2 && \text{by Lemma 21.4.19} \\
&= \epsilon\|AV_RV_R^\top - C\Phi^{-1}\Delta D^{-1}X^*\|_F^2 + \|AV_RV_R^\top - C\Phi^{-1}\Delta D^{-1}X^*\|_F^2 \\
&= \epsilon\|AV_RV_R^\top - C\Phi^{-1}\Delta D^{-1}X^*\|_F^2 + \|AV_RV_R^\top - C\Phi^{-1}\Delta D^{-1}(Z_2^\top AR^\dagger R)\|_F^2. && (21.13)
\end{aligned}$$

By the Pythagorean theorem and the definition of Z_2 (which means $Z_2 = C\Phi^{-1}\Delta D^{-1}$), we have,

$$\begin{aligned}
&\|AV_RV_R^\top - C\Phi^{-1}\Delta D^{-1}(Z_2^\top AR^\dagger R)\|_F^2 + \beta \\
&= \|AV_RV_R^\top - C\Phi^{-1}\Delta D^{-1}(Z_2^\top AR^\dagger R)\|_F^2 + \|A - AV_RV_R^\top\|_F^2 \\
&= \|A - C\Phi^{-1}\Delta D^{-1}(Z_2^\top AR^\dagger R)\|_F^2 \\
&= \|A - Z_2Z_2^\top AR^\dagger R\|_F^2. && (21.14)
\end{aligned}$$

Combining Equations (21.12), (21.13) and (21.14) together, we obtain,

$$\|A - CUR\|_F^2 \leq \epsilon\|AV_RV_R^\top - C\Phi^{-1}\Delta D^{-1}X^*\|_F^2 + \|A - Z_2Z_2^\top AR^\dagger R\|_F^2.$$

We want to show $\|AV_RV_R^\top - C\Phi^{-1}\Delta D^{-1}X^*\|_F^2 \leq \|A - Z_2Z_2^\top AR^\dagger R\|_F^2$,

$$\begin{aligned}
&\|AV_RV_R^\top - C\Phi^{-1}\Delta D^{-1}X^*\|_F^2 \\
&= \|AV_RV_R^\top - C\Phi^{-1}\Delta D^{-1}Z_2^\top AV_RV_R^\top\|_F^2 && \text{by } X^* = Z_2^\top AV_RV_R^\top \\
&\leq \|A - C\Phi^{-1}\Delta D^{-1}Z_2^\top A\|_F^2 && \text{by properties of projections} \\
&\leq \|A - C\Phi^{-1}\Delta D^{-1}Z_2^\top AR^\dagger R\|_F^2 && \text{by properties of projections} \\
&= \|A - Z_2Z_2^\top AR^\dagger R\|_F^2. && \text{by } Z_2 = C\Phi^{-1}\Delta D^{-1}
\end{aligned}$$

This completes the proof. □

Lemma 21.4.19 ([CW13])**.** *Let $A \in \mathbb{R}^{n\times d}$ have rank ρ and $B \in \mathbb{R}^{n\times r}$. Let $W \in \mathbb{R}^{r\times n}$ be a randomly chosen sparse subspace embedding with $r = \Omega(\rho^2\epsilon^{-2})$. Let $\widehat{X}^* = \arg\min_{X\in\mathbb{R}^{d\times r}} \|WAX - WB\|_F^2$ and let $X^* = \arg\min_{X\in\mathbb{R}^{d\times r}} \|AX - B\|_F^2$. Then with probability at least .99,*

$$\|A\widetilde{X}^* - B\|_F^2 \leq (1+\epsilon)\|AX^* - B\|_F^2.$$

end procedure

We provide two bicriteria CURT results in this Section. We first present a warm-up result. That result (Theorem 21.4.20) does not output tensor U and only guarantees that there is a rank-poly(k/ϵ) tensor U. Then we show the second result (Theorem 21.4.21), our second result is able to output tensor U. The U has rank poly(k/ϵ), but not k.

Theorem 21.4.20. *Given a 3rd order tensor $A \in \mathbb{R}^{n\times n\times n}$, for any $k \geq 1$, there exists an algorithm which takes $O(\mathrm{nnz}(A)) + n\,\mathrm{poly}(k, 1/\epsilon)$ time and outputs three matrices: $C \in \mathbb{R}^{n\times c}$, a subset of columns of A, $R \in \mathbb{R}^{n\times r}$ a subset of rows of A, and $T \in \mathbb{R}^{n\times t}$, a subset of tubes*

of A where $c = r = t = \text{poly}(k, 1/\epsilon)$, and there exists a tensor $U \in \mathbb{R}^{c \times r \times t}$ such that

$$\|(((U \cdot T^\top)^\top \cdot R^\top)^\top \cdot C^\top)^\top - A\|_F^2 \leq (1+\epsilon) \min_{\text{rank}-k \ A_k} \|A_k - A\|_F^2,$$

or equivalently,

$$\left\| \sum_{i=1}^{c} \sum_{j=1}^{r} \sum_{l=1}^{t} U_{i,j,l} \cdot C_i \otimes R_j \otimes T_l - A \right\|_F^2 \leq (1+\epsilon) \min_{\text{rank}-k \ A_k} \|A_k - A\|_F^2$$

holds with probability $9/10$.

Proof. We mainly analyze Algorithm 21.8 and it is easy to extend to Algorithm 21.9.

We fix $V^* \in \mathbb{R}^{n \times k}$ and $W^* \in \mathbb{R}^{n \times k}$. We define $Z_1 \in \mathbb{R}^{k \times n^2}$ where the i-th row of Z_1 is the vector $V_i \otimes W_i$. Choose sketching (Gaussian) matrix $S_1 \in \mathbb{R}^{n^2 \times s_1}$ (Definition 21.3.12), and let $\widehat{U} = A_1 S_1 (Z_1 S_1)^\dagger \in \mathbb{R}^{n \times k}$. Following a similar argument as in the previous theorem, we have

$$\|\widehat{U} Z_1 - A_1\|_F^2 \leq (1+\epsilon) \, \text{OPT} \, .$$

We fix $\widehat{U}$ and W^*. We define $Z_2 \in \mathbb{R}^{k \times n^2}$ where the i-th row of Z_2 is the vector $\widehat{U}_i \otimes W_i^*$. Choose sketching (Gaussian) matrix $S_2 \in \mathbb{R}^{n^2 \times s_2}$ (Definition 21.3.12), and let $\widehat{V} = A_2 S_2 (Z_2 S_2)^\dagger \in \mathbb{R}^{n \times k}$. Following a similar argument as in the previous theorem, we have

$$\|\widehat{V} Z_2 - A_2\|_F^2 \leq (1+\epsilon)^2 \, \text{OPT} \, .$$

We fix $\widehat{U}$ and $\widehat{V}$. Note that $\widehat{U} = A_1 S_1 (Z_1 S_1)^\dagger$ and $\widehat{V} = A_2 S_2 (Z_2 S_2)^\dagger$. We define $Z_3 \in \mathbb{R}^{k \times n^2}$ such that the i-th row of Z_3 is the vector $\widehat{U}_i \otimes \widehat{V}_i$. Let $z_3 = s_1 \cdot s_2$. We define

$Z_3' \in \mathbb{R}^{z_3 \times n^2}$ such that, $\forall i \in [s_1], \forall j \in [s_2]$, the $i + (j-1)s_1$-th row of Z_3' is the vector $(A_1 S_1)_i \otimes (A_2 S_2)_j$. We consider the following objective function,

$$\min_{W \in \mathbb{R}^{n \times k}, X \in \mathbb{R}^{k \times z_3}} \|WXZ_3' - A_3\|_F^2 \leq \min_{W \in \mathbb{R}^{n \times k}} \|WZ_3 - A_3\|_F^2 \leq (1+\epsilon)^2 \, \mathrm{OPT} \, .$$

Using Theorem 21.4.14, we can find a diagonal matrix $D_3 \in \mathbb{R}^{n^2 \times n^2}$ with $d_3 = O(z_3/\epsilon) = O(k^2/\epsilon^3)$ nonzero entries such that

$$\min_{X \in \mathbb{R}^{d_3 \times z_3}} \|A_3 D_3 X Z_3' - A_3\|_F^2 \leq (1+\epsilon)^3 \, \mathrm{OPT} \, .$$

In the following, we abuse notation and let $A_3 D_3 \in \mathbb{R}^{n \times d_3}$ by deleting zero columns. Let W' denote $A_3 D_3 \in \mathbb{R}^{n \times d_3}$. Then,

$$\min_{X \in \mathbb{R}^{d_3 \times z_3}} \|W' X Z_3' - A_3\|_F^2 \leq (1+\epsilon)^3 \, \mathrm{OPT} \, .$$

We fix $\widehat{U}$ and W'. Let $z_2 = s_1 \cdot d_3$. We define $Z_2' \in \mathbb{R}^{z_2 \times n^2}$ such that, $\forall i \in [s_1], \forall j \in [d_3]$, the $i + (j-1)s_1$-th row of Z_2' is the vector $(A_1 S_1)_i \otimes (A_3 D_3)_j$.

Using Theorem 21.4.14, we can find a diagonal matrix $D_2 \in \mathbb{R}^{n^2 \times n^2}$ with $d_2 = O(z_2/\epsilon) = O(s_1 d_3/\epsilon) = O(k^3/\epsilon^5)$ nonzero entries such that

$$\min_{X \in \mathbb{R}^{d_2 \times z_2}} \|A_2 D_2 X Z_2' - A_2\|_F^2 \leq (1+\epsilon)^4 \, \mathrm{OPT} \, .$$

Let V' denote $A_2 D_2$. Then,

$$\min_{X \in \mathbb{R}^{d_2 \times z_2}} \|V' X Z_2' - A_2\|_F^2 \leq (1+\epsilon)^4 \, \mathrm{OPT} \, .$$

We fix V' and W'. Let $z_1 = d_2 \cdot d_3$. We define $Z_1' \in \mathbb{R}^{z_1 \times n^2}$ such that, $\forall i \in [d_2], \forall j \in [d_3]$, the $i + (j-1)s_1$-th row of Z_1' is the vector $(A_2 D_2)_i \otimes (A_3 D_3)_j$.

Using Theorem 21.4.14, we can find a diagonal matrix $D_1 \in \mathbb{R}^{n^2 \times n^2}$ with $d_1 = O(z_1/\epsilon) = O(d_2 d_3/\epsilon) = O(k^5/\epsilon^9)$ nonzero entries such that

$$\min_{X \in \mathbb{R}^{d_1 \times z_1}} \|A_1 D_1 X Z_1' - A_1\|_F^2 \leq (1+\epsilon)^5 \operatorname{OPT}.$$

Let U' denote $A_1 D_1$. Then,

$$\min_{X \in \mathbb{R}^{d_1 \times z_1}} \|U' X Z_1' - A_1\|_F^2 \leq (1+\epsilon)^5 \operatorname{OPT}.$$

Putting U', V', W' all together, we complete the proof.

All the above analysis gives the running time $O(\operatorname{nnz}(A)) \log n + n^2 \operatorname{poly}(\log n, k, 1/\epsilon)$. To improve the running time, we need to use Algorithm 21.9, the similar analysis will go through, the running time will be improved to $O(\operatorname{nnz}(A) + n \operatorname{poly}(k, 1/\epsilon))$, but the sample complexity of c, r, k will be slightly worse (poly log factors). □

Theorem 21.4.21. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$, there exists an algorithm which takes $O(\operatorname{nnz}(A) + n \operatorname{poly}(k, 1/\epsilon))$ time and outputs three matrices: $C \in \mathbb{R}^{n \times c}$, a subset of columns of A, $R \in \mathbb{R}^{n \times r}$ a subset of rows of A, and $T \in \mathbb{R}^{n \times t}$, a subset of tubes of A, together with a tensor $U \in \mathbb{R}^{c \times r \times t}$ with $\operatorname{rank}(U) = k'$ where $c = r = t = \operatorname{poly}(k, 1/\epsilon)$ and $k' = \operatorname{poly}(k, 1/\epsilon)$ such that*

$$\|U(C, R, T) - A\|_F^2 \leq (1+\epsilon) \min_{\operatorname{rank}-k \ A_k} \|A_k - A\|_F^2,$$

or equivalently,

$$\left\| \sum_{i=1}^{c} \sum_{j=1}^{r} \sum_{l=1}^{t} U_{i,j,l} \cdot C_i \otimes R_j \otimes T_l - A \right\|_F^2 \leq (1+\epsilon) \min_{\operatorname{rank}-k \ A_k} \|A_k - A\|_F^2$$

holds with probability $9/10$.

Proof. The proof follows by combining Theorem 21.1.1 and Theorem 21.1.3 directly. □

21.4.7 CURT decomposition, $(1+\epsilon)$-approximation

21.4.7.1 Properties of leverage score sampling and BSS sampling

Notice that, the BSS algorithm is a deterministic procedure developed in [BSS12] for selecting rows from a matrix $A \in \mathbb{R}^{n \times d}$ (with $\|A\|_2 \leq 1$ and $\|A\|_F^2 \leq k$) using a selection matrix S so that

$$\|A^\top S^\top S A - A^\top A\|_2 \leq \epsilon.$$

The algorithm runs in $\text{poly}(n, d, 1/\epsilon)$ time. Using the ideas from [BW14] and [CEM+15], we are able to reduce the number of nonzero entries from $O(\epsilon^{-2}k \log k)$ to $O(\epsilon^{-2}k)$, and also improve the running time to input sparsity.

Lemma 21.4.22 (Leverage score preserves subspace embedding - Theorem 2.11 in [Woo14b])**.** *Given a* rank-k *matrix* $A \in \mathbb{R}^{n \times d}$*, via leverage score sampling, we can obtain a diagonal matrix* D *with* m *nonzero entries such that, letting* $B = DA$*, if* $m = O(\epsilon^{-2}k \log k)$*, then, with probability at least* 0.999*, for all* $x \in \mathbb{R}^d$*,*

$$(1 - \epsilon)\|Ax\|_2 \leq \|Bx\|_2 \leq (1 + \epsilon)\|Ax\|_2$$

Lemma 21.4.23. *Given a* rank-k *matrix* $A \in \mathbb{R}^{n \times d}$*, there exists an algorithm that runs in* $O(\text{nnz}(A) + n \,\text{poly}(k, 1/\epsilon))$ *time and outputs a matrix* B *containing* $O(\epsilon^{-2}k \log k)$ *re-weighted rows of* A*, such that with probability at least* 0.999*, for all* $x \in \mathbb{R}^d$*,*

$$(1 - \epsilon)\|Ax\|_2 \leq \|Bx\|_2 \leq (1 + \epsilon)\|Ax\|_2$$

Proof. We choose a sparse embedding matrix (Definition 21.3.10) $\Pi \in \mathbb{R}^{d \times s}$ with $s = \text{poly}(k/\epsilon)$. With probability at least 0.999, $\Pi^\top$ is a subspace embedding of $A^\top$. Thus, $\text{rank}(A\Pi) = \text{rank}(A)$. Also, the leverage scores of $A\Pi$ are the same as those of A. Thus, we can compute the leverage scores of $A\Pi$. The running time of computing $A\Pi$ is $O(\text{nnz}(A))$. Thus the total running time is $O(\text{nnz}(A) + n \,\text{poly}(k, 1/\epsilon))$. □

Lemma 21.4.24. *Let* B *denote a matrix which contains* $O(\epsilon^{-2}k \log k)$ *rows of* $A \in \mathbb{R}^{n \times d}$*. Choosing* Π *to be a sparse subspace embedding matrix of size* $d \times O(\epsilon^{-6}(k \log k)^2)$*, with probability at least* 0.999*,*

$$\|B\Pi\Pi^\top B^\top - BB^\top\|_2 \leq \epsilon\|B\|_2^2.$$

Combining Lemma 21.4.23, 21.4.24 and the BSS algorithm, we obtain:

Lemma 21.4.25. *Given a* rank-k *matrix* $A \in \mathbb{R}^{n \times d}$*, there exists an algorithm that runs in* $O(\mathrm{nnz}(A) + n\,\mathrm{poly}(k, 1/\epsilon))$ *time and outputs a sampling and rescaling diagonal matrix* S *that selects* $O(\epsilon^{-2}k)$ *re-weighted rows of* A*, such that, with probability at least* 0.999*,*

$$\|A^\top S^\top SA - A^\top A\|_2 \leq \epsilon \|A\|_2^2.$$

or equivalently, for all $x \in \mathbb{R}^d$*,*

$$(1-\epsilon)\|Ax\|_2 \leq \|SAx\|_2 \leq (1+\epsilon)\|Ax\|_2.$$

Proof. Using Lemma 21.4.23, we can obtain B. Then we apply a sparse subspace embedding matrix Π on the right of B. At the end, we run the BSS algorithm on $B\Pi$ and we are able to output $O(\epsilon^{-2}k)$ re-weighted rows of $B\Pi$. Using these rows, we are able to determine $O(\epsilon^{-2}k)$ re-weighted rows of A. □

21.4.7.2 Row sampling for linear regression

Theorem 21.4.26 (Theorem 5 in [CNW15])**.** *We are given* $A \in \mathbb{R}^{n \times d}$ *with* $\|A\|_2^2 \leq 1$ *and* $\|A\|_F^2 \leq k$*, and an* $\epsilon \in (0, 1)$*. There exists a diagonal matrix* S *with* $O(k/\epsilon^2)$ *nonzero entries such that*

$$\|(SA)^\top SA - A^\top A\|_2 \leq \epsilon.$$

Corollary 21.4.27. *Given a rank-*k *matrix* $A \in \mathbb{R}^{n \times d}$*, vector* $b \in \mathbb{R}^n$*, and parameter* $\epsilon > 0$*, let* $U \in \mathbb{R}^{n \times (k+1)}$ *denote an orthonormal basis of* $[A, b]$*. Let* $S \in \mathbb{R}^{n \times n}$ *denote a sampling and rescaling diagonal matrix according to Leverage score sampling and sparse BSS sampling of*

U with m nonzero entries. If $m = O(k)$, then S is a $(1 \pm 1/2)$ subspace embedding for U; if $m = O(k/\epsilon)$, then S satisfies $\sqrt{\epsilon}$-operator norm approximate matrix product for U.

Proof. This follows by Lemma 21.4.22, Lemma 21.4.24 and Theorem 21.4.26. □

Lemma 21.4.28 ([NW14])**.** *Given $A \in \mathbb{R}^{n \times d}$ and $b \in \mathbb{R}^n$, let $S \in \mathbb{R}^{n \times n}$ denote a sampling and rescaling diagonal matrix. Let x^* denote $\arg\min_x \|Ax - b\|_2^2$ and x' denote $\arg\min_x \|SAx - Sb\|_2^2$. If S is a $(1 \pm 1/2)$ subspace embedding for the column span of A, and ϵ' $(=\sqrt{\epsilon})$-operator norm approximate matrix product for U adjoined with $b - Ax^*$, then, with probability at least .999,*

$$\|Ax' - b\|_2^2 \leq (1 + \epsilon)\|Ax^* - b\|_2^2.$$

Proof. We define $\text{OPT} = \min_x \|Ax - b\|_2$. We define $x' = \arg\min_x \|SAx - Sb\|_2^2$ and $x^* = \arg\min_x \|Ax - b\|_2^2$. Let $w = b - Ax^*$. Let U denote an orthonormal basis of A. We can write $Ax' - Ax^* = U\beta$. Then, we have,

$$\begin{aligned}
\|Ax' - b\|_2^2 &= \|Ax' - Ax^* + AA^\dagger b - b\|_2^2 && \text{by } x^* = A^\dagger b \\
&= \|U\beta + (UU^\top - I)b\|_2^2 \\
&= \|Ax^* - Ax'\|_2^2 + \|Ax^* - b\|_2^2 && \text{by Pythagorean Theorem} \\
&= \|U\beta\|_2^2 + \text{OPT}^2 \\
&= \|\beta\|_2^2 + \text{OPT}^2 \,.
\end{aligned}$$

If S is a $(1 \pm 1/2)$ subspace embedding for U, then we can show

$$
\begin{aligned}
&\|\beta\|_2 - \|U^\top S^\top SU\beta\|_2 \\
&\leq \|\beta - U^\top S^\top SU\beta\|_2 && \text{by triangle inequality} \\
&= \|(I - U^\top S^\top SU)\beta\|_2 \\
&\leq \|I - U^\top S^\top SU\|_2 \cdot \|\beta\|_2 \\
&\leq \frac{1}{2}\|\beta\|_2.
\end{aligned}
$$

Thus, we obtain

$$\|U^\top S^\top SU\beta\|_2 \geq \|\beta\|_2/2.$$

Next, we can show

$$
\begin{aligned}
\|U^\top S^\top SU\beta\|_2 &= \|U^\top S^\top S(Ax' - Ax^*)\|_2^2 \\
&= \|U^\top S^\top S(A(SA)^\dagger Sb - Ax^*)\|_2 && \text{by } x' = (SA)^\dagger Sb \\
&= \|U^\top S^\top S(b - Ax^*)\|_2 && \text{by } SA(SA)^\dagger = I \\
&= \|U^\top S^\top Sw\|_2. && \text{by } w = b - Ax^*
\end{aligned}
$$

We define $U' = \begin{bmatrix} U & w/\|w\|_2 \end{bmatrix}$. We define X and y to satisfy $U = U'X$ and $w = U'y$. Then,

we have

$$\begin{aligned}
&\|U^\top S^\top S w\|_2 \\
&= \|U^\top S^\top S w - U^\top w\|_2 && \text{by } U^\top w = 0 \\
&= \|X^\top U'^\top S^\top S U' y - X^\top U'^\top U' y\|_2 \\
&= \|X^\top (U'^\top S^\top S U' - I) y\|_2 \\
&\le \|X\|_2 \cdot \|U'^\top S^\top S U' - I\|_2 \cdot \|y\|_2 \\
&\le \epsilon' \|X\|_2 \|y\|_2 \\
&= \epsilon' \|U\|_2 \|w\|_2 \\
&= \epsilon' \operatorname{OPT}, && \text{by } \|U\|_2 = 1 \text{ and } \|w\|_2 = \operatorname{OPT}
\end{aligned}$$

where the fifth inequality follows since S satisfies ϵ'-operator norm approximate matrix product for the column span of U adjoined with w.

Putting it all together, we have

$$\begin{aligned}
\|Ax' - b\|_2^2 &= \|Ax^* - b\|_2^2 + \|Ax^* - Ax'\|_2^2 \\
&= \operatorname{OPT}^2 + \|\beta\|_2^2 \\
&\le \operatorname{OPT}^2 + 4\|U^\top S^\top S w\|_2^2 \\
&\le \operatorname{OPT}^2 + 4(\epsilon' \operatorname{OPT})^2 \\
&\le (1+\epsilon) \operatorname{OPT}^2 . && \text{by } \epsilon' = \frac{1}{2}\sqrt{\epsilon}.
\end{aligned}$$

Finally, note that S satisfies ϵ'-operator norm approximate matrix product for U adjoined with w if it is a $(1 \pm \epsilon')$-subspace embedding for U adjoined with w, which holds using BSS sampling by Theorem 5 of [CNW15] with $O(d/\epsilon)$ samples. □

21.4.7.3 Leverage scores for multiple regression

Lemma 21.4.29 (see, e.g., Lemma 32 in [CW13] among other places)**.** *Given matrix $A \in \mathbb{R}^{n \times d}$ with orthonormal columns, and parameter $\epsilon > 0$, if $S \in \mathbb{R}^{n \times n}$ is a sampling and rescaling diagonal matrix according to the leverage scores of A where the number of nonzero entries is $t = O(1/\epsilon^2)$, then, for any $B \in \mathbb{R}^{n \times m}$, we have*

$$\|A^\top S^\top S B - A^\top B\|_F^2 < \epsilon^2 \|A\|_F^2 \|B\|_F^2,$$

holds with probability at least 0.9999*.*

Corollary 21.4.30. *Given matrix $A \in \mathbb{R}^{n \times d}$ with orthonormal columns, and parameter $\epsilon > 0$, if $S \in \mathbb{R}^{n \times n}$ is a sampling and rescaling diagonal matrix according to the leverage scores of A with m nonzero entries, then if $m = O(d \log d)$, then S is a $(1 \pm 1/2)$ subspace embedding for A. If $m = O(d/\epsilon)$, then S satisfies $\sqrt{\epsilon/d}$-Frobenius norm approximate matrix product for A.*

Proof. This follows by Lemma 21.4.22 and Lemma 21.4.29. □

Lemma 21.4.31 ([NW14])**.** *Given $A \in \mathbb{R}^{n \times d}$ and $B \in \mathbb{R}^{n \times m}$, let $S \in \mathbb{R}^{n \times n}$ denote a sampling and rescaling matrix according to A. Let X^* denote $\arg\min_X \|AX - B\|_F^2$ and X' denote $\arg\min_X \|SAX - SB\|_F^2$. Let U denote an orthonormal basis for A. If S is a $(1 \pm 1/2)$ subspace embedding for U, and satisfies $\epsilon' (= \sqrt{\epsilon/d})$-Frobenius norm approximate matrix product for U, then, we have that*

$$\|AX' - B\|_F^2 \leq (1 + \epsilon)\|AX^* - B\|_F^2$$

holds with probability at least 0.999*.*

Proof. We define $\mathrm{OPT} = \min_X \|AX - B\|_F$. Let $A = U\Sigma V^\top$ denote the SVD of A. Since A has rank k, U and V have k columns. We can write $A(X' - X^*) = U\beta$. Then, we have

$$\begin{aligned}
\|AX' - B\|_F^2 &= \|AX' - AX^* + AA^\dagger B - B\|_F^2 && \text{by } X^* = A^\dagger B \\
&= \|U\beta + (UU^\top - I)B\|_F^2 \\
&= \|AX^* - AX'\|_F^2 + \|AX^* - B\|_F^2 && \text{by Pythagorean Theorem} \\
&= \|U\beta\|_F^2 + \mathrm{OPT}^2 \\
&= \|\beta\|_F^2 + \mathrm{OPT}^2 \,. && (21.15)
\end{aligned}$$

If S is a $(1 \pm 1/2)$ subspace embedding for U, then we can show,

$$\begin{aligned}
&\|\beta\|_F - \|U^\top S^\top SU\beta\|_F \\
\leq\ &\|\beta - U^\top S^\top SU\beta\|_F && \text{by triangle inequality} \\
=\ &\|(I - U^\top S^\top SU)\beta\|_F \\
\leq\ &\|(I - U^\top S^\top SU)\|_2 \cdot \|\beta\|_F && \text{by } \|AB\|_F \leq \|A\|_2 \|B\|_F \\
\leq\ &\frac{1}{2}\|\beta\|_F. && \text{by } \|(I - U^\top S^\top SU)\|_2 \leq 1/2
\end{aligned}$$

Thus, we obtain

$$\|U^\top S^\top SU\beta\|_F \geq \|\beta\|_F/2. \tag{21.16}$$

Next, we can show

$$\begin{aligned}
\|U^\top S^\top SU\beta\|_F &= \|U^\top S^\top S(AX' - AX^*)\|_F \\
&= \|U^\top S^\top S(A(SA)^\dagger Sb - AX^*)\|_F && \text{by } X' = (SA)^\dagger SB \\
&= \|U^\top S^\top S(B - AX^*)\|_F. && \text{by } SA(SA)^\dagger = I
\end{aligned}$$

Then, we can show

$$\begin{aligned}\|U^\top S^\top S(B - AX^*)\|_F &\leq \epsilon' \|U^\top\|_F \|B - AX^*\|_F \\ &= \epsilon' \sqrt{d}\, \mathrm{OPT}, \end{aligned} \tag{21.17}$$

where the first step follows from Lemma 21.4.29, the second step follows from $\|U\|_F = \sqrt{d}$ and $\|B - AX^*\|_F = \mathrm{OPT}$.

Putting it all together, we have

$$\begin{aligned}\|AX' - B\|_F^2 &= \|AX^* - B\|_F^2 + \|AX^* - AX'\|_F^2 \\ &= \mathrm{OPT}^2 + \|\beta\|_F^2 && \text{by Equation (21.15)} \\ &\leq \mathrm{OPT}^2 + 4\|U^\top S^\top S w\|_F^2 && \text{by Equation (21.16)} \\ &\leq \mathrm{OPT}^2 + 4(\epsilon' \sqrt{d}\, \mathrm{OPT})^2 && \text{by Equation (21.17)} \\ &\leq (1+\epsilon)\, \mathrm{OPT}^2 . && \text{by } \epsilon' = \frac{1}{2}\sqrt{\epsilon/d} \end{aligned}$$

□

21.4.7.4 Sampling columns according to leverage scores implicitly, improving polynomial running time to nearly linear running time

This section explains an algorithm that is able to sample from the leverage scores from the $\odot$ product of two matrices U, V without explicitly writing down $U \odot V$. To build this algorithm we combine TensorSketch, some ideas from [DMIMW12] and some ideas from [AKO11, MW10]. Finally, we are able to improve the running time of sampling columns according to leverage scores from $\Omega(n^2)$ to $\widetilde{O}(n)$. Given two matrices $U, V \in \mathbb{R}^{k \times n}$, we define $A \in \mathbb{R}^{k \times n_1 n_2}$ to be the matrix where the i-th row of A is the vectorization of $U^i \otimes V^i$, $\forall i \in [k]$.

Naïvely, in order to sample $O(\mathrm{poly}(k, 1/\epsilon))$ rows from $A^\top$ according to leverage scores, we need to write down n^2 leverage scores. This approach will take at least $\Omega(n^2)$ running time. In the rest of this section, we will explain how to do it in $O(n \cdot \mathrm{poly}(\log n, k, 1/\epsilon))$ time. In Section 21.5.1, we will explain how to extend this idea from 3rd order tensors to general q-th order tensors and remove the $\mathrm{poly}(\log n)$ factor from running time, i.e., obtain $O(n \cdot \mathrm{poly}(k, 1/\epsilon))$ time.

Lemma 21.4.32. *Given two matrices $U \in \mathbb{R}^{k \times n_1}$ and $V \in \mathbb{R}^{k \times n_2}$, there exists an algorithm that takes $O((n_1 + n_2) \cdot \mathrm{poly}(\log(n_1 n_2), k) \cdot R_{\mathrm{samples}})$ time and samples R_{samples} columns of $U \odot V \in \mathbb{R}^{k \times n_1 n_2}$ according to the leverage scores of $R^{-1}(U \odot V)$, where R is the R of a QR factorization.*

Proof. We choose $\Pi \in \mathbb{R}^{n_1 n_2 \times s_1}$ to be a TensorSketch. Then, according to Section 21.3.10, we can compute R^{-1} in $n \cdot \mathrm{poly}(\log n, k, 1/\epsilon)$ time, where R is the R in a QR-factorization. We want to sample columns from $U \odot V$ according to the square of the ℓ_2-norms of each column of $R^{-1}(U \odot V)$. However, explicitly writing down the matrix $R^{-1}(U \odot V)$ takes $k n_1 n_2$ time, and the number of columns is already $n_1 n_2$. The goal is to sample columns from $R^{-1}(U \odot V)$ without explicitly computing the square of the ℓ_2-norm of each column.

The first simple observation is that the following two sampling procedures are equivalent in terms of the column samples of a matrix that they take. (1) We sample a single entry from the matrix $R^{-1}(U \odot V)$ proportional to its squared value. (2) We sample a column from the matrix $R^{-1}(U \odot V)$ proportional to its squared ℓ_2-norm. Let the (i, j_1, j_2)-th entry denote the entry in the i-th row and the $(j_1 - 1)n_2 + j_2$-th column. We can show, for a

particular column $(j_1-1)n_2+j_2$,

$$\begin{aligned}
&\Pr[\text{sample an entry from the } (j_1-1)n_2+j_2 \text{ th column of a matrix}] \\
=& \sum_{i=1}^{k} \Pr[\text{sample the } (i,j_1,j_2)\text{-th entry of matrix}] \\
=& \sum_{i=1}^{k} \frac{|(R^{-1}(U\odot V))_{i,(j_1-1)n_2+j_2}|^2}{\|R^{-1}(U\odot V)\|_F^2} \\
=& \frac{\|(R^{-1}(U\odot V))_{(j_1-1)n_2+j_2}\|^2}{\|R^{-1}(U\odot V)\|_F^2} \\
=& \Pr[\text{sample the } (j_1-1)n_2+j_2 \text{ th column of matrix}]. \qquad (21.18)
\end{aligned}$$

Thus, it is sufficient to show how to sample a single entry from matrix $R^{-1}(U\odot V)$ proportional to its squared value without writing down all of the entries of a $k\times n_1n_2$ matrix.

We choose a Gaussian matrix $G_1\in\mathbb{R}^{g_1\times k}$ with $g_1=O(\epsilon^{-2}\log(n_1n_2))$. By Claim 21.4.33 we can reduce the length of each column vector of matrix $R^{-1}U\odot V$ from k to g_1 while preserving the squared ℓ_2-norm of all columns simultaneously. Thus, we obtain a new matrix $GR^{-1}(U\odot V)\in\mathbb{R}^{g_1\times n_1n_2}$, and sampling from this new matrix is equivalent to sampling from the original matrix $R^{-1}(U\odot V)$.

In the following paragraphs, we explain a sampling procedure (also described in Procedure FastTensorLeverageScore in Algorithm 21.10) which contains three sampling steps. The first step is sampling i from $[g_1]$, the second step is sampling j_2 from $[n_2]$, and the last step is sampling j_1 from $[n_1]$.

For each $j_1\in[n_1]$, let U_{j_1} denote the j_1-th column of U. For each $i\in[g_1]$, let G_1^i denote the i-th row of matrix $G_1\in\mathbb{R}^{g_1\times k}$, let $U'^i\in\mathbb{R}^{k\times n_1}$ denote a matrix where the j_1-th column is $(G^iR^{-1})^\top\circ U_{j_1}\in\mathbb{R}^k, \forall j\in[n_1]$. Then, using Claim 21.4.37, we have that $(G^iR^{-1})\cdot(U\odot V)\in$

$\mathbb{R}^{n_1 n_2}$ is a row vector where the entry in the $(j_1-1)n_2+j_2$-th coordinate is the entry in the j_1-th row and j_2-th column of matrix $(U'^{i\top}V) \in \mathbb{R}^{n_1 \times n_2}$. Further, the squared ℓ_2-norm of vector $(G^i R^{-1}) \cdot (U \odot V)$ is equal to the squared Frobenius norm of matrix $(U'^{i\top}V)$. Thus, sampling i proportional to the squared ℓ_2-norm of vector $(G^i R^{-1}) \cdot (U \odot V)$ is equivalent to sampling i proportional to the squared Frobenius norm of matrix $(U'^{i\top}V)$. Naïvely, computing the Frobenius norm of an $n_1 \times n_2$ matrix requires $O(n_1 n_2)$ time. However, we can choose a Gaussian matrix $G_{2,i} \in \mathbb{R}^{g_2 \times n_1}$ to sample according to the value $\|(G_{2,i}U'^{i\top})V\|_F^2$, which can be computed in $O((n_1+n_2)g_2 k)$ time. By claim 21.4.35, $\|(G_{2,i}U'^{i\top})V\|_F^2 \approx \|(U'^{i\top})V\|_F^2$ with high probability. So far, we have finished the first step of the sampling procedure.

For the second step of the sampling procedure, we need to sample j_2 from $[n_2]$. To do that, we need to compute the squared ℓ_2-norm of each column of $U'^{i\top}V \in \mathbb{R}^{n_1 \times n_2}$. This can be done by choosing another Gaussian matrix $G_{3,i} \in \mathbb{R}^{g_3 \times n_1}$. For all $j_2 \in [n_2]$, by Claim 21.4.36, we have $\|G_{3,i}U'^{i\top}V_{j_2}\|_2^2 \approx \|U'^{i\top}V_{j_2}\|_2^2$. Also, for $j_2 \in [n_2]$, $\|G_{3,i}U'^{i\top}V_{j_2}\|_2^2$ can be computed in nearly linear in n_1+n_2 time.

For the third step of the sampling procedure, we need to sample j_1 from $[n_1]$. Since we already have i and j_2 from the previous two steps, we can directly compute $|(U'^{i\top})^{j_1}V_{j_2}|^2$, for all j_1. This only takes $O(n_1 k)$ time.

Overall, the running time is $O((n_1+n_2)\cdot \mathrm{poly}(\log(n_1 n_2), k, 1/\epsilon))$. Because our estimates are accurate enough, our sampling probabilities are also good approximations to the leverage score sampling probabilities. Putting it all together, we complete the proof. □

Claim 21.4.33. *Given matrix $R^{-1}(U \odot V) \in \mathbb{R}^{k \times n_1 n_2}$, let $G_1 \in \mathbb{R}^{g_1 \times k}$ denote a Gaussian matrix with $g_1 = (\epsilon^{-2}\log(n_1 n_2))$. Then with probability at least $1 - 1/\mathrm{poly}(n_1 n_2)$, we have:*

for all $j \in [n_1 n_2]$,

$$(1-\epsilon)\|R^{-1}(U \odot V)_j\|_2^2 \leq \|G_1 R^{-1}(U \odot V)_j\|_2^2 \leq (1+\epsilon)\|R^{-1}(U \odot V)_j\|_2^2.$$

Proof. This follows by the Johnson-Lindenstrauss Lemma. □

Claim 21.4.34. *For a fixed* $i \in [g_1]$, *let* $G_{2,i} \in \mathbb{R}^{g_2 \times n_1}$ *denote a Gaussian matrix with* $g_2 = O(\epsilon^{-2}\log(n_1 n_2))$. *Then with probability at least* $1 - 1/\operatorname{poly}(n_1 n_2)$, *we have: for all* $j_2 \in [n_2]$,

$$(1-\epsilon)\|U'^{i\top} V_{j_2}\|_2^2 \leq \|(G_{2,i} U'^{i\top}) V_{j_2}\|_2 \leq (1+\epsilon)\|U'^{i\top} V_{j_2}\|_2^2.$$

By taking the union bound over all $i \in [g_1]$, we obtain a stronger claim,

Claim 21.4.35. *With probability at least* $1 - 1/\operatorname{poly}(n_1 n_2)$, *we have : for all* $i \in [g_1]$, *for all* $j_2 \in [n_2]$,

$$(1-\epsilon)\|U'^{i\top} V_{j_2}\|_2^2 \leq \|(G_{2,i} U'^{i\top}) V_{j_2}\|_2 \leq (1+\epsilon)\|U'^{i\top} V_{j_2}\|_2^2.$$

Similarly, if we choose $G_{3,i}$ to be a Gaussian matrix, we can obtain the same result as for $G_{2,i}$:

Claim 21.4.36. *With probability at least* $1 - 1/\operatorname{poly}(n_1 n_2)$, *we have : for all* $i \in [g_1]$, *for all* $j_2 \in [n_2]$,

$$(1-\epsilon)\|U'^{i\top} V_{j_2}\|_2^2 \leq \|(G_{3,i} U'^{i\top}) V_{j_2}\|_2 \leq (1+\epsilon)\|U'^{i\top} V_{j_2}\|_2^2.$$

Claim 21.4.37. *For any* $i \in [g_1]$, $j_1 \in [n_1]$, $j_2 \in [n_2]$, *let* G_1^i *denote the* i*-th row of matrix* $G_1 \in \mathbb{R}^{g_1 \times k}$. *Let* $(U \odot V)_{(j_1-1)n_2+j_2}$ *denote the* $(j_1-1)n_2 + j_2$*-th column of matrix* $\mathbb{R}^{k \times n_1 n_2}$.

Let $(U'^{i\top})^{j_1}$ *denote the* j_1*-th row of matrix* $(U'^{i\top}) \in \mathbb{R}^{n_1 \times k}$*. Let* V_{j_2} *denote the* j_2*-th column of matrix* $V \in \mathbb{R}^{k \times n_2}$*. Then, we have*

$$G_1^i R^{-1} (U \odot V)_{(j_1-1)n_2+j_2} = (U'^{i\top})^{j_1} V_{j_2}.$$

Proof. This follows by,

$$G_1^i R^{-1} (U \odot V)_{(j_1-1)n_2+j_2} = G_1^i R^{-1} (U_{j_1} \circ V_{j_2}) = (G_1^i R^{-1} \circ (U_{j_1})^\top) V_{j_2} = (U'^{i\top})^{j_1} V_{j_2}.$$

□

Lemma 21.4.38. *Given* $A \in \mathbb{R}^{n \times n^2}$*,* $V, W \in \mathbb{R}^{k \times n}$*, for any* $\epsilon > 0$*, there exists an algorithm that runs in* $O(n \cdot \mathrm{poly}(k, 1/\epsilon))$ *time and outputs a diagonal matrix* $D \in \mathbb{R}^{n^2 \times n^2}$ *with* $m = O(k \log k + k/\epsilon)$ *nonzero entries such that,*

$$\|\widehat{U}(V \odot W) - A\|_F^2 \leq (1+\epsilon) \min_{U \in \mathbb{R}^{n \times k}} \|U(V \odot W) - A\|_F^2,$$

holds with probability at least 0.999*, where* $\widehat{U}$ *denotes the optimal solution to* $\min_U \|U(V \odot W)D - AD\|_F^2$*.*

Proof. This follows by combining Theorem 21.5.1, Corollary 21.4.30, and Lemma 21.4.31. □

Remark 21.4.1. Replacing Theorem 21.5.1 (Algorithm 21.15) by Lemma 21.4.32 (Algorithm 21.10), we can obtain a slightly different version of Lemma 21.4.38 with $n\,\mathrm{poly}(\log n, k, 1/\epsilon)$ running time, where the dependence on k is better.

21.4.7.5 Input sparsity time algorithm

Theorem 21.4.39. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, let $k \geq 1$, and let $U_B, V_B, W_B \in \mathbb{R}^{n \times k}$ denote a rank-k, α-approximation to A. Then there exists an algorithm which takes $O(\text{nnz}(A) + n \,\text{poly}(k, 1/\epsilon))$ time and outputs three matrices $C \in \mathbb{R}^{n \times c}$ with columns from A, $R \in \mathbb{R}^{n \times r}$ with rows from A, $T \in \mathbb{R}^{n \times t}$ with tubes from A, and a tensor $U \in \mathbb{R}^{c \times r \times t}$ with $\text{rank}(U) = k$ such that $c = r = t = O(k \log k + k/\epsilon)$, and*

$$\left\| \sum_{i=1}^{c} \sum_{j=1}^{r} \sum_{l=1}^{t} U_{i,j,l} \cdot C_i \otimes R_j \otimes T_l - A \right\|_F^2 \leq (1+\epsilon)\alpha \min_{\text{rank}-k \ A'} \|A' - A\|_F^2$$

holds with probability $9/10$.

Proof. We define

$$\mathrm{OPT} := \min_{\mathrm{rank}-k\ A'} \|A' - A\|_F^2.$$

We already have three matrices $U_B \in \mathbb{R}^{n\times k}$, $V_B \in \mathbb{R}^{n\times k}$ and $W_B \in \mathbb{R}^{n\times k}$ and these three matrices provide a rank-k, α-approximation to A, i.e.,

$$\left\| \sum_{i=1}^{k} (U_B)_i \otimes (V_B)_i \otimes (W_B)_i - A \right\|_F^2 \leq \alpha\, \mathrm{OPT}\,. \tag{21.19}$$

Let $B_1 = V_B^\top \odot W_B^\top \in \mathbb{R}^{k\times n^2}$ denote the matrix where the i-th row is the vectorization of $(V_B)_i \otimes (W_B)_i$. Let $D_1 \in \mathbb{R}^{n^2\times n^2}$ be a sampling and rescaling matrix corresponding to sampling by the leverage scores of $B_1^\top$; there are d_1 nonzero entries on the diagonal of D_1. Let $A_i \in \mathbb{R}^{n\times n^2}$ denote the matrix obtained by flattening A along the i-th direction, for each $i \in [3]$.

Define $U^* \in \mathbb{R}^{n\times k}$ to be the optimal solution to $\min_{U\in\mathbb{R}^{n\times k}} \|UB_1 - A_1\|_F^2$, $\widehat{U} = A_1 D_1 (B_1 D_1)^\dagger \in \mathbb{R}^{n\times k}$, and $V_0 \in \mathbb{R}^{n\times k}$ to be the optimal solution to $\min_{V\in\mathbb{R}^{n\times k}} \|V \cdot (\widehat{U}^\top \odot W_B^\top) - A_2\|_F^2$. Due to Lemma 21.4.38, if $d_1 = O(k\log k + k/\epsilon)$ then with constant probability, we have

$$\|\widehat{U}B_1 - A_1\|_F^2 \leq \alpha_{D_1} \|U^* B_1 - A_1\|_F^2. \tag{21.20}$$

Recall that $(\widehat{U}^\top \odot W_B^\top) \in \mathbb{R}^{k\times n^2}$ denotes the matrix where the i-th row is the vector-

ization of $\widehat{U}_i \otimes (W_B)_i$, $\forall i \in [k]$. Now, we can show,

$$\begin{aligned}
&\|V_0 \cdot (\widehat{U}^\top \odot W_B^\top) - A_2\|_F^2 \\
\leq\ & \|\widehat{U} B_1 - A_1\|_F^2 && \text{by } V_0 = \arg\min_{V \in \mathbb{R}^{n \times k}} \|V \cdot (\widehat{U}^\top \odot W_B^\top) - A_2\|_F^2 \\
\leq\ & \alpha_{D_1} \|U^* B_1 - A_1\|_F^2 && \text{by Equation (21.20)} \\
\leq\ & \alpha_{D_1} \|U_B B_1 - A_1\|_F^2 && \text{by } U^* = \arg\min_{U \in \mathbb{R}^{n \times k}} \|U B_1 - A_1\|_F^2 \\
\leq\ & \alpha_{D_1} \alpha \, \mathrm{OPT} \,. && \text{by Equation (21.19)}
\end{aligned} \tag{21.21}$$

We define $B_2 = \widehat{U}^\top \odot W_B^\top$. Let $D_2 \in \mathbb{R}^{n^2 \times n^2}$ be a sampling and rescaling matrix corresponding to the leverage scores of $B_2^\top$. Suppose there are d_2 nonzero entries on the diagonal of D_2.

Define $V^* \in \mathbb{R}^{n \times k}$ to be the optimal solution to $\min_{V \in \mathbb{R}^{n \times k}} \|V B_2 - A_2\|_F^2$, $\widehat{V} = A_2 D_2 (B_2 D_2)^\dagger \in \mathbb{R}^{n \times k}$, $W_0 \in \mathbb{R}^{n \times k}$ to be the optimal solution to $\min_{W \in \mathbb{R}^{n \times k}} \|W \cdot (\widehat{U}^\top \odot \widehat{V}^\top) - A_3\|_F^2$, and V' to be the optimal solution to $\min_{V \in \mathbb{R}^{n \times k}} \|V B_2 D_2 - A_2 D_2\|_F^2$.

Due to Lemma 21.4.38, with constant probability, we have

$$\|\widehat{V} B_2 - A_2\|_F^2 \leq \alpha_{D_2} \|V^* B_2 - A_2\|_F^2. \tag{21.22}$$

Recall that $(\widehat{U}^\top \odot \widehat{V}^\top) \in \mathbb{R}^{k \times n^2}$ denotes the matrix where the i-th row is the vector-

ization of $\widehat{U}_i \otimes \widehat{V}_i$, $\forall i \in [k]$. Now, we can show,

$$\begin{aligned}
&\|W_0 \cdot (\widehat{U}^\top \odot \widehat{V}^\top) - A_3\|_F^2 \\
\leq\ & \|\widehat{V} B_2 - A_2\|_F^2 && \text{by } W_0 = \arg\min_{W \in \mathbb{R}^{n \times k}} \|W \cdot (\widehat{U}^\top \odot \widehat{V}^\top) - A_3\|_F^2 \\
\leq\ & \alpha_{D_2} \|V^* B_2 - A_2\|_F^2 && \text{by Equation (21.22)} \\
\leq\ & \alpha_{D_2} \|V_0 B_2 - A_2\|_F^2 && \text{by } V^* = \arg\min_{V \in \mathbb{R}^{n \times k}} \|V B_2 - A_2\|_F^2 \\
\leq\ & \alpha_{D_2} \alpha_{D_1} \alpha \, \mathrm{OPT} \,. && \text{by Equation (21.21)}
\end{aligned} \tag{21.23}$$

We define $B_3 = \widehat{U}^\top \odot \widehat{V}^\top$. Let $D_3 \in \mathbb{R}^{n^2 \times n^2}$ denote a sampling and rescaling matrix corresponding to sampling by the leverage scores of $B_3^\top$. Suppose there are d_3 nonzero entries on the diagonal of D_3.

Define $W^* \in \mathbb{R}^{n \times k}$ to be the optimal solution to $\min_{W \in \mathbb{R}^{n \times k}} \|W B_3 - A_3\|_F^2$, $\widehat{W} = A_3 D_3 (B_3 D_3)^\dagger \in \mathbb{R}^{n \times k}$, and W' to be the optimal solution to $\min_{W \in \mathbb{R}^{n \times k}} \|W B_3 D_3 - A_3 D_3\|_F^2$.

Due to Lemma 21.4.38 with constant probability, we have

$$\|\widehat{W} B_3 - A_3\|_F^2 \leq \alpha_{D_3} \|W^* B_3 - A_3\|_F^2. \tag{21.24}$$

Now we can show,

$$\begin{aligned}
\|\widehat{W} B_3 - A_3\|_F^2 &\leq \alpha_{D_3} \|W^* B_3 - A_3\|_F^2, && \text{by Equation (21.24)} \\
&\leq \alpha_{D_3} \|W_0 B_3 - A_3\|_F^2, && \text{by } W^* = \arg\min_{W \in \mathbb{R}^{n \times k}} \|W B_3 - A_3\|_F^2 \\
&\leq \alpha_{D_3} \alpha_{D_2} \alpha_{D_1} \alpha \, \mathrm{OPT} \,. && \text{by Equation (21.23)}
\end{aligned}$$

This implies,

$$\left\| \sum_{i=1}^k \widehat{U}_i \otimes \widehat{V}_i \otimes \widehat{W}_i - A \right\|_F^2 \leq O(1) \alpha \, \mathrm{OPT}^2 \,.$$

where $\widehat{U} = A_1 D_1 (B_1 D_1)^\dagger$, $\widehat{V} = A_2 D_2 (B_2 D_2)^\dagger$, $\widehat{W} = A_3 D_3 (B_3 D_3)^\dagger$.

By Lemma 21.4.38, we need to set $d_1 = d_2 = d_3 = O(k \log k + k/\epsilon)$. Note that $B_1 = (V_B^\top \odot W_B^\top)$. Thus D_1 can be found in $n \cdot \mathrm{poly}(k, 1/\epsilon)$ time. Because D_1 has a small number of nonzero entries on the diagonal, we can compute $B_1 D_1$ quickly without explicitly writing down B_1. Also $A_1 D_1$ can be computed in $\mathrm{nnz}(A)$ time. Using $(A_1 D_1)$ and $(B_1 D_1)$, we can compute $\widehat{U}$ in $n\,\mathrm{poly}(k, 1/\epsilon)$ time. In a similar way, we can compute B_2, D_2, B_3, and D_3. Since tensor U is constructed based on three $\mathrm{poly}(k, 1/\epsilon)$ size matrices, $(B_1 D_1)^\dagger$, $(B_2 D_2)^\dagger$, and $(B_3 D_3)^\dagger$, the overall running time is $O(\mathrm{nnz}(A) + n\,\mathrm{poly}(k, 1/\epsilon))$ □

21.4.7.6 Optimal sample complexity algorithm

Theorem 21.4.40. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, let $k \geq 1$, and let $U_B, V_B, W_B \in \mathbb{R}^{n \times k}$ denote a rank-k, α-approximation to A. Then there exists an algorithm which takes $O(\mathrm{nnz}(A) \log n + n^2\,\mathrm{poly}(\log n, k, 1/\epsilon))$ time and outputs three matrices: $C \in \mathbb{R}^{n \times c}$ with columns from A, $R \in \mathbb{R}^{n \times r}$ with rows from A, $T \in \mathbb{R}^{n \times t}$ with tubes from A, and a tensor $U \in \mathbb{R}^{c \times r \times t}$ with $\mathrm{rank}(U) = k$ such that $c = r = t = O(k/\epsilon)$, and*

$$\left\| \sum_{i=1}^{c} \sum_{j=1}^{r} \sum_{l=1}^{t} U_{i,j,l} \cdot C_i \otimes R_j \otimes T_l - A \right\|_F^2 \leq (1+\epsilon)\alpha \min_{\mathrm{rank}-k\ A'} \|A' - A\|_F^2$$

holds with probability 9/10.

Proof. The proof is almost the same as the proof of Theorem 21.4.39. The only difference is that instead of using Theorem 21.4.38, we use Theorem 21.4.14. □

21.4.8 Face-based selection and decomposition

Previously we provided column-based tensor CURT algorithms, which are algorithms that can select a subset of columns from each of the three dimensions. Here we provide two face-based tensor CURT decomposition algorithms. The first algorithm runs in polynomial time and is a bicriteria algorithm (the number of samples is poly(k/ϵ)). The second algorithm needs to start with a rank-k $(1 + O(\epsilon))$-approximate solution, which we then show how to combine with our previous algorithm. Both of our algorithms are able to select a subset of column-row faces, a subset of row-tube faces and a subset of column-tube faces. The second

algorithm is able to output U, but the first algorithm is not.

Theorem 21.4.41. *Given a 3rd order tensor $A \in \mathbb{R}^{n\times n\times n}$, for any $k \geq 1$, there exists an algorithm which takes $O(\text{nnz}(A)) \log n + n^2 \,\text{poly}(\log n, k, 1/\epsilon)$ time and outputs three tensors : a subset $C \in \mathbb{R}^{c\times n\times n}$ of row-tube faces of A, a subset $R \in \mathbb{R}^{n\times r\times n}$ of column-tube faces of A, and a subset $T \in \mathbb{R}^{n\times n\times t}$ of column-row faces of A, where $c = r = t = \text{poly}(k, 1/\epsilon)$, and for which there exists a tensor $U \in \mathbb{R}^{tn\times cn\times rn}$ for which*

$$\|U(T_1, C_2, R_3) - A\|_F^2 \leq (1+\epsilon) \min_{\text{rank}-k\ A'} \|A' - A\|_F^2,$$

or equivalently,

$$\left\| \sum_{i=1}^{tn} \sum_{j=1}^{cn} \sum_{l=1}^{rn} U_{i,j,l} \cdot (T_1)_i \otimes (C_2)_j \otimes (R_3)_l - A \right\|_F^2 \leq (1+\epsilon) \min_{\text{rank}-k\ A'} \|A' - A\|_F^2.$$

Proof. We fix $V^* \in \mathbb{R}^{n \times k}$ and $W^* \in \mathbb{R}^{n \times k}$. We define $Z_1 \in \mathbb{R}^{k \times n^2}$ where the i-th row of Z_1 is the vector $V_i \otimes W_i$. Choose a sketching (Gaussian) matrix $S_1 \in \mathbb{R}^{n^2 \times s_1}$ (Definition 21.3.12), and let $\widehat{U} = A_1 S_1 (Z_1 S_1)^\dagger \in \mathbb{R}^{n \times k}$. Following a similar argument as in the previous theorem, we have

$$\|\widehat{U} Z_1 - A_1\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}\,.$$

We fix $\widehat{U}$ and W^*. We define $Z_2 \in \mathbb{R}^{k \times n^2}$ where the i-th row of Z_2 is the vector $\widehat{U}_i \otimes W_i^*$. Choose a sketching (Gaussian) matrix $S_2 \in \mathbb{R}^{n^2 \times s_2}$ (Definition 21.3.12), and let $\widehat{V} = A_2 S_2 (Z_2 S_2)^\dagger \in \mathbb{R}^{n \times k}$. Following a similar argument as in the previous theorem, we have

$$\|\widehat{V} Z_2 - A_2\|_F^2 \leq (1+\epsilon)^2\,\mathrm{OPT}\,.$$

We fix $\widehat{U}$ and $\widehat{V}$. Note that $\widehat{U} = A_1 S_1 (Z_1 S_1)^\dagger$ and $\widehat{V} = A_2 S_2 (Z_2 S_2)^\dagger$. We define $Z_3 \in \mathbb{R}^{k \times n^2}$ such that the i-th row of Z_3 is the vector $\widehat{U}_i \otimes \widehat{V}_i$. Let $z_3 = s_1 \cdot s_2$. We define $Z_3' \in \mathbb{R}^{z_3 \times n^2}$ such that, $\forall i \in [s_1], \forall j \in [s_2]$, the $i + (j-1)s_1$-th row of Z_3' is the vector $(A_1 S_1)_i \otimes (A_2 S_2)_j$.

We define $U_3 \in \mathbb{R}^{n \times z_3}$ to be the matrix where the $i + (j-1)s_1$-th column is $(A_1 S_1)_i$ and $V_3 \in \mathbb{R}^{n \times z_3}$ to be the matrix where the $i + (j-1)s_1$-th column is $(A_2 S_2)_j$. Then $Z_3' = (U_3^\top \odot V_3^\top)$.

We first have,

$$\min_{W \in \mathbb{R}^{n \times k}, X \in \mathbb{R}^{k \times z_3}} \|W X Z_3' - A_3\|_F^2 \leq \min_{W \in \mathbb{R}^{n \times k}} \|W Z_3 - A_3\|_F^2 \leq (1+\epsilon)^2\,\mathrm{OPT}\,.$$

Now consider the following objective function,

$$\min_{W \in \mathbb{R}^{n \times z_3}} \|V_3 \cdot (W^\top \odot U_3^\top) - A_2\|_F^2.$$

Let D_3 denote a sampling and rescaling diagonal matrix according to $V_1 \in \mathbb{R}^{n \times z_3}$, let d_3 denote the number of nonzero entries of D_3. Then we have

$$\begin{aligned} & \min_{W \in \mathbb{R}^{n \times z_3}} \|D_3 V_3 \cdot (W^\top \odot U_3^\top) - D_3 A_2\|_F^2 \\ = & \min_{W \in \mathbb{R}^{n \times z_3}} \|U_3 \otimes (D_3 V_3) \otimes W - A(I, D_3, I)\|_F^2 \\ = & \min_{W \in \mathbb{R}^{n \times z_3}} \|W \cdot (U_3^\top \odot (D_3 V_3)^\top) - (A(I, D_3, I))_3\|_F^2, \end{aligned}$$

where the first equality follows by retensorizing the objective function, and the second equality follows by flattening the tensor along the third dimension.

Let $\overline{Z}_3$ denote $(U_3^\top \odot (D_3 V_3)^\top) \in \mathbb{R}^{z_3 \times n d_3}$ and $W' = (A(I, D_3, I))_3 \in \mathbb{R}^{n \times n d_3}$. Using Theorem 21.4.14, we can find a diagonal matrix $D_3 \in \mathbb{R}^{n^2 \times n^2}$ with $d_3 = O(z_3/\epsilon) = O(k^2/\epsilon^3)$ nonzero entries such that

$$\|U_3 \otimes V_3 \otimes (W' Z_3^\dagger) - A\|_F^2 \leq (1+\epsilon)^3 \, \mathrm{OPT} \, .$$

We define $U_2 = U_3 \in \mathbb{R}^{n \times z_2}$ with $z_2 = z_3$. We define $W_2 = W' \overline{Z}_3^\dagger \in \mathbb{R}^{n \times z_2}$ with $z_2 = z_3$. We consider,

$$\min_{V \in \mathbb{R}^{n \times z_2}} \|U_2 \cdot (V^\top \odot W_2^\top) - A_1\|_F^2.$$

Let D_2 denote a sampling and rescaling matrix according to U_2, and let d_2 denote the number

of nonzero entries of D_2. Then, we have

$$\begin{aligned}
&\min_{V \in \mathbb{R}^{n \times z_2}} \|D_2 U_2 \cdot (V^\top \odot W_2^\top) - D_2 A_1\|_F^2 \\
= &\min_{V \in \mathbb{R}^{n \times z_2}} \|D_2 U_2 \otimes V \otimes W_2 - A(D_2, I, I)\|_F^2 \\
= &\min_{V \in \mathbb{R}^{n \times z_2}} \|V \cdot (W_2^\top \odot (D_2 U_2)^\top) - (A(D_2, I, I))_2\|_F^2,
\end{aligned}$$

where the first equality follows by retensorizing the objective function, and the second equality follows by flattening the tensor along the second dimension.

Let $\overline{Z}_2$ denote $(W_2^\top \odot (D_2 U_2)^\top) \in \mathbb{R}^{z_2 \times n d_2}$ and $V' = (A(D_2, I, I))_2 \in \mathbb{R}^{n \times n d_2}$. Using Theorem 21.4.14, we can find a diagonal matrix $D_2 \in \mathbb{R}^{n^2 \times n^2}$ with $d_2 = O(z_2/\epsilon)$ nonzero entries such that

$$\|U_2 \otimes (V' \overline{Z}_2^\dagger) \otimes W_2 - A\|_F^2 \leq (1+\epsilon)^4 \operatorname{OPT}.$$

We define $W_1 = W_2 \in \mathbb{R}^{n \times z_1}$ with $z_1 = z_2$, and define $V_1 = (V' \overline{Z}_2^\dagger) \in \mathbb{R}^{n \times z_1}$ with $z_1 = z_2$.

Let D_1 denote a sampling and rescaling matrix according to W_1, and let d_1 denote the number of nonzero entries of D_1. Then we have

$$\begin{aligned}
&\min_{U \in \mathbb{R}^{n \times z_1}} \|D_1 W_1 \cdot (U^\top \odot V_1^\top) - D_1 A_3\|_F^2 \\
= &\min_{U \in \mathbb{R}^{n \times z_1}} \|U \otimes V_1 \otimes (D_1 W_1) - A(I, I, D_1)\|_F^2 \\
= &\min_{U \in \mathbb{R}^{n \times z_1}} \|U \cdot (V_1^\top \odot (D_1 W_1)^\top) - A(I, I, D_1)_1\|_F^2
\end{aligned}$$

where the first equality follows by unflattening the objective function, and second equality follows by flattening the tensor along the first dimension.

Let $\overline{Z}_1$ denote $(V_1^\top \odot (D_1 W_1)^\top) \in \mathbb{R}^{z_1 \times nd_1}$, and $U' = A(I, I, D_1)_1 \in \mathbb{R}^{n \times nd_1}$. Using Theorem 21.4.14, we can find a diagonal matrix $D_1 \in \mathbb{R}^{n^2 \times n^2}$ with $d_1 = O(z_1/\epsilon)$ nonzero entries such that

$$\|(U'\overline{Z}_1^\dagger) \otimes (V_1) \otimes W_1 - A\|_F^2 \leq (1+\epsilon)^5 \,\mathrm{OPT},$$

which means,

$$\|(U'\overline{Z}_1^\dagger) \otimes (V'\overline{Z}_2^\dagger) \otimes (W'\overline{Z}_3^\dagger) - A\|_F^2 \leq (1+\epsilon)^5 \,\mathrm{OPT}\,.$$

Putting U', V', W' together completes the proof. □

Corollary 21.4.42. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$, there exists an algorithm which takes $O(\mathrm{nnz}(A)) + n^2\,\mathrm{poly}(k, 1/\epsilon)$ time and outputs three tensors : a subset $C \in \mathbb{R}^{c \times n \times n}$ of row-tube faces of A, a subset $R \in \mathbb{R}^{n \times r \times n}$ of column-tube faces of A, and a subset $T \in \mathbb{R}^{n \times n \times t}$ of column-row faces of A, where $c = r = t = \mathrm{poly}(k, 1/\epsilon)$, so that there exists a tensor $U \in \mathbb{R}^{tn \times cn \times rn}$ for which*

$$\|U(T_1, C_2, R_3) - A\|_F^2 \leq (1+\epsilon) \min_{\mathrm{rank}-k \;\; A'} \|A' - A\|_F^2,$$

or equivalently,

$$\left\| \sum_{i=1}^{tn} \sum_{j=1}^{cn} \sum_{l=1}^{rn} U_{i,j,l} \cdot (T_1)_i \otimes (C_2)_j \otimes (R_3)_l - A \right\|_F^2 \leq (1+\epsilon) \min_{\mathrm{rank}-k \;\; A'} \|A' - A\|_F^2$$

Proof. If we allow a $\mathrm{poly}(k/\epsilon)$ factor increase in running time and a $\mathrm{poly}(k/\epsilon)$ factor increase in the number of faces selected, then instead of using generalized row subset selection, which has running time depending on $\log n$, we can use the technique in Section 21.6 to avoid the $\log n$ factor. □

21.4.8.2 CURT decomposition

Theorem 21.4.43. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, let $k \geq 1$, and let $U_B, V_B, W_B \in \mathbb{R}^{n \times k}$ denote a rank-k, α-approximation to A. Then there exists an algorithm which takes $O(\mathrm{nnz}(A)) \log n + n^2 \, \mathrm{poly}(\log n, k, 1/\epsilon)$ time and outputs three tensors: $C \in \mathbb{R}^{c \times n \times n}$ with row-tube faces from A, $R \in \mathbb{R}^{n \times r \times n}$ with colum-tube faces from A, $T \in \mathbb{R}^{n \times n \times t}$ with column-row faces from A, and a (factorization of a) tensor $U \in \mathbb{R}^{tn \times cn \times rn}$ with $\mathrm{rank}(U) = k$ for which $c = r = t = O(k/\epsilon)$ and*

$$\|U(T_1, C_2, R_3) - A\|_F^2 \leq (1 + \epsilon)\alpha \min_{\mathrm{rank}-k \ A'} \|A' - A\|_F^2,$$

or equivalently,

$$\left\| \sum_{i=1}^{tn} \sum_{j=1}^{cn} \sum_{l=1}^{rn} U_{i,j,l} \cdot (T_1)_i \otimes (C_2)_j \otimes (R_3)_l - A \right\|_F^2 \leq (1+\epsilon)\alpha \min_{\text{rank}-k \ A'} \|A' - A\|_F^2$$

holds with probability $9/10$.

Proof. We already have three matrices $U_B \in \mathbb{R}^{n\times k}$, $V_B \in \mathbb{R}^{n\times k}$ and $W_B \in \mathbb{R}^{n\times k}$ and these three matrices provide a rank-k, α-approximation to A, i.e.,

$$\|U_B \otimes V_B \otimes W_B - A\|_F^2 \leq \alpha \underbrace{\min_{\text{rank}-k \ A'} \|A' - A\|_F^2}_{\text{OPT}}.$$

We can consider the following problem,

$$\min_{U \in \mathbb{R}^{n\times k}} \|W_B \cdot (U^\top \odot V_B^\top) - A_3\|_F^2.$$

Let D_1 denote a sampling and rescaling diagonal matrix according to W_B, and let d_1 denote the number of nonzero entries of D_1. Then we have

$$\begin{aligned}
&\min_{U \in \mathbb{R}^{n\times k}} \|(D_1 W_B) \cdot (U^\top \odot V_B^\top) - D_1 A_3\|_F^2 \\
=&\min_{U \in \mathbb{R}^{n\times k}} \|U \otimes V_B \otimes D_1 W_B - A(I, I, D_1)\|_F^2 \\
=&\min_{U \in \mathbb{R}^{n\times k}} \|U \cdot (V_B^\top \odot (D_1 W_B)^\top) - (A(I, I, D_1))_1\|_F^2,
\end{aligned}$$

where the first equality follows by retensorizing the objective function, and the second equality follows by flattening the tensor along the first dimension. Let Z_1 denote $V_B^\top \odot (D_1 W_B)^\top \in \mathbb{R}^{k\times nd_1}$, and define $\widehat{U} = (A(I, I, D_1))_1 Z_1^\dagger \in \mathbb{R}^{n\times k}$. Then we have

$$\|\widehat{U} \otimes V_B \otimes W_B - A\|_F^2 \leq (1+\epsilon)\alpha \,\text{OPT}\,.$$

In the second step, we fix $\widehat{U}$ and W_B, and consider the following objective function,

$$\min_{V \in \mathbb{R}^{n \times k}} \|\widehat{U} \cdot (V^\top \odot W_B) - A_1\|_F^2.$$

Let D_2 denote a sampling and rescaling matrix according to $\widehat{U}$, and let d_2 denote the number of nonzero entries of D_2. Then we have,

$$\begin{aligned} & \min_{V \in \mathbb{R}^{n \times k}} \|(D_2 \widehat{U}) \cdot (V^\top \odot W_B^\top) - D_2 A_1\|_F^2 \\ = & \min_{V \in \mathbb{R}^{n \times k}} \|(D_2 \widehat{U}) \otimes V \otimes W_B - A(D_2, I, I)\|_F^2 \\ = & \min_{V \in \mathbb{R}^{n \times k}} \|V \cdot (W_B^\top \odot (D_2 \widehat{U})^\top) - (A(D_2, I, I))_2\|_F^2, \end{aligned}$$

where the first equality follows by unflattening the objective function, and the second equality follows by flattening the tensor along the second dimension. Let Z_2 denote $(W_B^\top \odot (D_2 \widehat{U})^\top) \in \mathbb{R}^{k \times n d_2}$, and define $\widehat{V} = (A(D_2, I, I))_2 (Z_2)^\dagger \in \mathbb{R}^{n \times k}$. Then we have,

$$\|\widehat{U} \otimes \widehat{V} \otimes W_B - A\|_F^2 \leq (1+\epsilon)^2 \alpha \, \mathrm{OPT} \, .$$

In the third step, we fix $\widehat{U}$ and $\widehat{V}$, and consider the following objective function,

$$\min_{W \in \mathbb{R}^{n \times k}} \|\widehat{V} \cdot (W \odot \widehat{U}) - A_2\|_F^2.$$

Let D_3 denote a sampling and rescaling matrix according to $\widehat{V}$, and let d_3 denote the number of nonzero entries of D_3. Then we have,

$$\begin{aligned} & \min_{W \in \mathbb{R}^{n \times k}} \|(D_3 \widehat{V}) \cdot (W^\top \odot \widehat{U}^\top) - D_3 A_2\|_F^2 \\ = & \min_{W \in \mathbb{R}^{n \times k}} \|\widehat{U} \otimes (D_3 \widehat{V}) \otimes W - A(I, D_3, I)\|_F^2 \\ = & \min_{W \in \mathbb{R}^{n \times k}} \|W \cdot (\widehat{U}^\top \odot (D_3 \widehat{V})^\top) - (A(I, D_3, I))_3\|_F^2, \end{aligned}$$

where the first equality follows by retensorizing the objective function, and the second equality follows by flattening the tensor along the third dimension. Let Z_3 denote $(\widehat{U}^\top \odot (D_3 \widehat{V})^\top) \in \mathbb{R}^{k \times nd_3}$, and define $\widehat{W} = (A(I, D_3, I))_3 (Z_3)^\dagger$. Putting it all together, we have,

$$\|\widehat{U} \otimes \widehat{V} \otimes \widehat{W} - A\|_F^2 \leq (1+\epsilon)^3 \alpha \, \mathrm{OPT} \, .$$

This implies

$$\|(A(I, I, D_1))_1 Z_1^\dagger \otimes (A(D_2, I, I))_2 Z_2^\dagger \otimes (A(I, D_3, I))_3 Z_3^\dagger - A\|_F^2 \leq (1+\epsilon)^3 \alpha \, \mathrm{OPT} \, .$$

□

21.4.9 Solving small problems

Theorem 21.4.44. *Let* $\max_i\{t_i, d_i\} \leq n$. *Given a* $t_1 \times t_2 \times t_3$ *tensor* A *and three matrices: a* $t_1 \times d_1$ *matrix* T_1, *a* $t_2 \times d_2$ *matrix* T_2, *and a* $t_3 \times d_3$ *matrix* T_3, *if for any* $\delta > 0$ *there exists a solution to*

$$\min_{X_1,X_2,X_3} \left\| \sum_{i=1}^{k} (T_1X_1)_i \otimes (T_2X_2)_i \otimes (T_3X_3)_i - A \right\|_F^2 := \mathrm{OPT},$$

and each entry of X_i *can be expressed using* $O(n^\delta)$ *bits, then there exists an algorithm that takes* $n^{O(\delta)} \cdot 2^{O(d_1k+d_2k+d_3k)}$ *time and outputs three matrices:* $\widehat{X}_1$, $\widehat{X}_2$, *and* $\widehat{X}_3$ *such that* $\|(T_1\widehat{X}_1) \otimes (T_2\widehat{X}_2) \otimes (T_3\widehat{X}_3) - A\|_F^2 = \mathrm{OPT}$.

Proof. For each $i \in [3]$, we can create $t_i \times d_i$ variables to represent matrix X_i. Let x denote this list of variables. Let B denote tensor $\sum_{i=1}^{k} (T_1X_1)_i \otimes (T_2X_2)_i \otimes (T_3X_3)_i$ and let $B_{i,j,l}(x)$ denote an entry of tensor B (which can be thought of as a polynomial written in terms of x). Then we can write the following objective function,

$$\min_x \sum_{i=1}^{t_1} \sum_{j=1}^{t_2} \sum_{l=1}^{t_3} (B_{i,j,l}(x) - A_{i,j,l})^2.$$

We slightly modify the above objective function to obtain a new objective function,

$$\begin{aligned} \min_{x,\sigma} \ & \sum_{i=1}^{t_1} \sum_{j=1}^{t_2} \sum_{l=1}^{t_3} (B_{i,j,l}(x) - A_{i,j,l})^2, \\ \text{s.t. } & \|x\|_2^2 \leq 2^{O(n^\delta)}, \end{aligned}$$

where the last constraint is unharmful, because there exists a solution that can be written using $O(n^\delta)$ bits. Note that the number of inequality constraints in the above system is

$O(1)$, the degree is $O(1)$, and the number of variables is $v = (d_1k + d_2k + d_3k)$. Thus by Theorem 21.3.2, the minimum nonzero cost is at least

$$(2^{O(n^\delta)})^{-2^{O(v)}}.$$

It is clear that the upper bound on the cost is at most $2^{O(n^\delta)}$. Thus the number of binary search steps is at most $\log(2^{O(n^\delta)})2^{O(v)}$. In each step of the binary search, we need to choose a cost C between the lower bound and the upper bound, and write down the polynomial system,

$$\sum_{i=1}^{t_1}\sum_{j=1}^{t_2}\sum_{l=1}^{t_3}(B_{i,j,l}(x) - A_{i,j,l})^2 \leq C,$$
$$\|x\|_2^2 \leq 2^{O(n^\delta)}.$$

Using Theorem 21.3.1, we can determine if there exists a solution to the above polynomial system. Since the number of variables is v, and the degree is $O(1)$, the number of inequality constraints is $O(1)$. Thus, the running time is

$$\text{poly(bitsize)} \cdot (\#\,\text{constraints} \cdot \text{degree})^{\#\,\text{variables}} = n^{O(\delta)}2^{O(v)}.$$

□

21.5 Extension to general q-th order tensors

This section provides the details for our extensions from 3rd order tensors to general q-th order tensors. In most practical applications, the order q is a constant. Thus, to simplify the analysis, we use $O_q(\cdot)$ to hide dependencies on q.

21.5.1 Fast sampling of columns according to leverage scores, implicitly

This section explains an algorithm that is able to sample from the leverage scores from the $\odot$ product of q matrices $U_1, U_2, \cdots, U_q$ without explicitly writing down $U_1 \odot U_2 \odot \cdots U_q$. To build this algorithm we combine TensorSketch, some ideas from [DMIMW12], and some techniques from [AKO11, MW10]. Finally, we improve the running time for sampling columns according to the leverage scores from $\mathrm{poly}(n)$ to $\widetilde{O}(n)$. Given q matrices $U_1, U_2, \cdots, U_q$, with each such matrix U_i having size $k \times n_i$, we define $A \in \mathbb{R}^{k \times \prod_{i=1}^q n_i}$ to be the matrix where the i-th row of A is the vectorization of $U_1^i \otimes U_2^i \otimes \cdots \otimes U_q^i$, $\forall i \in [k]$. Naïvely, in order to sample $\mathrm{poly}(k, 1/\epsilon)$ rows from A according to the leverage scores, we need to write down $\prod_{i=1}^q n_i$ leverage scores. This approach will take at least $\prod_{i=1}^q n_i$ running time. In the remainder of this section, we will explain how to do it in $O_q(n \cdot \mathrm{poly}(k, 1/\epsilon))$ time for any constant p, and $\max_{i \in [q]} n_i \leq n$.

Theorem 21.5.1. *Given q matrices $U_1 \in \mathbb{R}^{k \times n_1}$, $U_2 \in \mathbb{R}^{k \times n_2}$, $\cdots$, $U_q \in \mathbb{R}^{k \times n_q}$, let $\max_i n_i \leq n$. There exists an algorithm that takes $O_q(n \cdot \mathrm{poly}(k, 1/\epsilon) \cdot R_{\mathrm{samples}})$ time and samples R_{samples} columns of $U_1 \odot U_2 \odot \cdots \odot U_q \in \mathbb{R}^{k \times \prod_{i=1}^q n_i}$ according to the leverage scores of $U_1 \odot U_2 \odot \cdots \odot U_q$.*

Proof. Let $\max_i n_i \leq n$. First, choosing Π_0 to be a TensorSketch, we can compute R^{-1} in $O_q(n \, \mathrm{poly}(k, 1/\epsilon))$ time, where R is the R in a QR-factorization. We want to sample columns from $U_1 \odot U_2 \odot \cdots \odot U_q$ according to the square of the ℓ_2-norm of each column of $R^{-1}(U_1 \odot U_2 \odot \cdots U_q)$. The issue is the number of columns of this matrix is already $\prod_{i=1}^q n_i$. The goal is to sample columns from $R^{-1}(U_1 \odot U_2 \odot \cdots U_q)$ without explicitly computing the square of the ℓ_2-norm of each column.

Similarly as in the proof of Lemma 21.4.32, we have the observation that the following

Algorithm 21.15 Fast Tensor Leverage Score Sampling, for General q-th Order

      $\beta_i \leftarrow |(V_{q-1})^{\widehat{j_{q-1}}}(U_q)_i|^2$.
    end for
    Sample $\widehat{j_q}$ from $[n_q]$ with probability $\beta_i / \sum_{i'=1}^{n_q} \beta_{i'}$.
    $\mathcal{S} \leftarrow \mathcal{S} \cup (\widehat{j_1}, \cdots, \widehat{j_q})$.
  end for
  Convert $\mathcal{S}$ into a diagonal matrix D with at most R_{samples} nonzero entries.
  return D. ▷ Diagonal matrix $D \in \mathbb{R}^{n_1 n_2 \cdots n_q \times n_1 n_2 \cdots n_q}$
end procedure

two sampling procedures are equivalent in terms of sampling a column of a matrix: (1) We sample a single entry from matrix $R^{-1}(U_1 \odot U_2 \odot \cdots \odot U_q)$ proportional to its squared value,

(2) We sample a column from matrix $R^{-1}(U_1 \odot U_2 \odot \cdots \odot U_q)$ proportional to its squared ℓ_2-norm. Let the $(i, j_1, j_2, \cdots, j_q)$-th entry denote the entry in the i-th row and the j-th column, where

$$j = \sum_{l=1}^{q-1} (j_l - 1) \prod_{t=l+1}^{q} n_t + j_q.$$

Similarly to Equation (21.18), we can show, for a particular column j,

$$\Pr[\text{we sample an entry from the } j\text{-th column of matrix}] = \Pr[\text{we sample the } j\text{-th column of a matrix}].$$

Thus, it is sufficient to show how to sample a single entry from matrix $R^{-1}(U_1 \odot U_2 \odot \cdots \odot U_q)$ proportional to its squared value without writing down all the entries of the $k \times \prod_{i=1}^{q} n_i$ matrix.

Let V_0 denote R^{-1}. Let n_0 denote the number of rows of V_0.

In the next few paragraphs, we describe a sampling procedure (procedure FastTensorLeverageScoreGeneralOrder in Algorithm 21.15) which first samples $\widehat{j_0}$ from $[n_0]$, then samples $\widehat{j_1}$ from $[n_1]$, $\cdots$, and at the end samples $\widehat{j_q}$ from $[n_q]$.

In the first step, we want to sample $\widehat{j_0}$ from $[n_0]$ proportional to the squared ℓ_2-norm of that row. To do this efficiently, we choose $\Pi_1 \in \mathbb{R}^{\prod_{i=1}^{q} n_i \times s_1}$ to be a TensorSketch to sketch on the right of $V_0(U_1 \odot U_2 \odot \cdots \odot U_q)$. By Section 21.3.10, as long as $s_1 = O_q(\mathrm{poly}(k, 1/\epsilon))$, then Π_1 is a $(1 \pm \epsilon)$-subspace embedding matrix. Thus with probability $1 - 1/\Omega(q)$, for all $i \in [n_0]$,

$$\|(V_0)^i((U_1 \odot U_2 \odot \cdots \odot U_q)\Pi_1)\|_2^2 = (1 \pm \epsilon)\|(V_0)^i((U_1 \odot U_2 \odot \cdots \odot U_q))\|_2^2,$$

which means we can sample $\widehat{j_0}$ from $[n_0]$ in $O_q(n\,\mathrm{poly}(k, 1/\epsilon))$ time.

In the second step, we have already obtained $\widehat{j_0}$. Using that row of V_0 with U_1, we can form a new matrix $V_1 \in \mathbb{R}^{n_1 \times k}$ in the following sense,

$$(V_1)^i = (V_0)^{\widehat{j_0}} \circ (U_1)_i^\top, \forall i \in [n_1],$$

where $(V_1)^i$ denotes the i-th row of matrix V_1, $(V_0)^{\widehat{j_0}}$ denotes the $\widehat{j_0}$-th row of V_0 and $(U_1)_i$ is the i-th column of U_1. Another important observation is, the entry in the $(j_1, j_2, \cdots, j_q)$-th coordinate of vector $(V_0)^{\widehat{j_0}}(U_1 \odot U_2 \odot \cdots \odot U_q)$ is the same as the entry in the j_1-th row and $(j_2, \cdots, j_q)$-th column of matrix $V_1(U_2 \odot U_3 \odot \cdots \odot U_q)$. Thus, sampling j_1 is equivalent to sampling j_1 from the new matrix $V_1(U_2 \odot U_3 \odot \cdots \odot U_q)$ proportional to the squared ℓ_2-norm of that row. We still have the computational issue that the length of the row vector is very long. To deal with this, we can choose $\Pi_2 \in \mathbb{R}^{\prod_{i=2}^q n_i \times s_2}$ to be a TensorSketch to multiply on the right of $V_1(U_2 \odot U_3 \odot \cdots \odot U_q)$.

By Section 21.3.10, as long as $s_2 = O_q(\mathrm{poly}(k, 1/\epsilon))$, then Π_2 is a $(1 \pm \epsilon)$-subspace embedding matrix. Thus with probability $1 - 1/\Omega(q)$, for all $i \in [n_1]$,

$$\|(V_1)^i((U_2 \odot \cdots \odot U_q)\Pi_2)\|_2^2 = (1 \pm \epsilon)\|(V_1)^i((U_2 \odot \cdots \odot U_q))\|_2^2,$$

which means we can sample $\widehat{j_1}$ from $[n_1]$ in $O_q(n\,\mathrm{poly}(k, 1/\epsilon))$ time.

We repeat the above procedure until we obtain each of $\widehat{j_0}, \widehat{j_1}, \cdots, \widehat{j_q}$. Note that the last one, $\widehat{j_q}$, is easier, since the length of the vector is already small enough, and so we do not need to use TensorSketch for it.

By Section 21.3.10, the time for multiplying by TensorSketch is $O_q(n\,\mathrm{poly}(k, 1/\epsilon))$. Setting ϵ to be a small constant, and taking a union bound over $O(q)$ events completes the proof. □

Lemma 21.5.2. *Given $A \in \mathbb{R}^{n_0 \times \prod_{i=1}^{q} n_i}$, $U_1, U_2, \cdots, U_q \in \mathbb{R}^{k \times n}$, for any $\epsilon > 0$, there exists an algorithm that runs in $O(n \cdot \mathrm{poly}(k, 1/\epsilon))$ time and outputs a diagonal matrix $D \in \mathbb{R}^{\prod_{i=1}^{q} n_i \times \prod_{i=1}^{q} n_i}$ with $m = O(k \log k + k/\epsilon)$ nonzero entries such that,*

$$\|\widehat{U}(U_1 \odot U_2 \odot \cdots \odot U_q) - A\|_F^2 \leq (1+\epsilon) \min_{U \in \mathbb{R}^{n \times k}} \|U(U_1 \odot U_2 \odot \cdots \odot U_q) - A\|_F^2,$$

holds with probability at least 0.999*, where $\widehat{U}$ denotes the optimal solution of*

$$\min_{U \in \mathbb{R}^{n_0 \times k}} \|U(U_1 \odot U_2 \odot \cdots \odot U_q)D - AD\|_F^2.$$

Proof. This follows by combining Theorem 21.5.1, Corollary 21.4.30, and Lemma 21.4.31. □

21.5.2 General iterative existential proof

Algorithm 21.16 General q-th Order Iterative Existential Proof

procedure GeneralIterativeExistentialProof(A, n, k, q, ϵ) ▷ Section 21.5.2
  Fix $U_1^*, U_2^*, \cdots, U_q^* \in \mathbb{R}^{n \times k}$.
  for $i = 1 \to q$ **do**
    Choose sketching matrix $S_i \in \mathbb{R}^{n^{q-1} \times s_i}$ with $s_i = O_q(k/\epsilon)$.
    Define $Z_i \in \mathbb{R}^{k \times n^{q-1}}$ to be $\bigodot_{j<i} \widehat{U}_j^\top \odot \bigodot_{j'>i} U_{j'}^{*\top}$.
    Let A_i denote the matrix obtained by flattening tensor A along the i-th dimension.
    Define $\widehat{U}_i$ to be $A_i S_i (Z_i S_i)^\dagger$.
  end for
  return $\widehat{U}_1, \widehat{U}_2, \cdots, \widehat{U}_q$.
end procedure

Given a q-th order tensor $A \in \mathbb{R}^{n \times n \times \cdots \times n}$, we fix $U_1^*, U_2^*, \cdots, U_q^* \in \mathbb{R}^{n \times k}$ to be the best rank-k solution (if it does not exist, then we replace it by a good approximation, as discussed). We define $\mathrm{OPT} = \|U_1^* \otimes U_2^* \otimes \cdots \otimes U_q^* - A\|_F^2$. Our iterative proof works as follows. We first obtain the objective function,

$$\min_{U_1 \in \mathbb{R}^{n \times k}} \|U_1 \cdot Z_1 - A_1\|_F^2 \leq \mathrm{OPT},$$

where A_1 is a matrix obtained by flattening tensor A along the first dimension, $Z_1 = (U_2^{*\top} \odot U_3^{*\top} \odot \cdots \odot U_q^{*\top})$ denotes a $k \times n^{q-1}$ matrix. Choosing $S_1 \in \mathbb{R}^{n^{q-1} \times s_1}$ to be a Gaussian sketching matrix with $s_1 = O(k/\epsilon)$, we obtain a smaller problem,

$$\min_{U_1 \in \mathbb{R}^{n \times k}} \|U_1 \cdot Z_1 S_1 - A_1 S_1\|_F^2.$$

We define $\widehat{U}_1$ to be $A_1 S_1 (Z_1 S_1)^\dagger \in \mathbb{R}^{n \times k}$, which gives,

$$\|\widehat{U}_1 \cdot Z_1 - A_1\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}\,.$$

After retensorizing the above, we have,

$$\|\widehat{U}_1 \otimes U_2^* \otimes \cdots \otimes U_q^* - A\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}\,.$$

In the second round, we fix $\widehat{U}_1$, U_3^*, $\cdots$, $U_q^* \in \mathbb{R}^{n\times k}$, and choose $S_2 \in \mathbb{R}^{n^{q-1}\times s_2}$ to be a Gaussian sketching matrix with $s_2 = O(k/\epsilon)$. We define $Z_2 \in \mathbb{R}^{k\times n^{q-1}}$ to be $(\widehat{U}_1^\top \odot U_3^{*\top} \odot \cdots \odot U_q^{*\top})$. We define $\widehat{U}_2$ to be $A_2 S_2 (Z_2 S_2)^\dagger \in \mathbb{R}^{n\times k}$. Then, we have

$$\|\widehat{U}_1 \otimes \widehat{U}_2 \otimes U_3^* \otimes \cdots \otimes U_q^* - A\|_F^2 \leq (1+\epsilon)^2\,\mathrm{OPT}\,.$$

We repeat the above process, where in the i-th round we fix $\widehat{U}_1, \cdots, \widehat{U}_{i-1}$, U_{i+1}^*, $\cdots$, $U_q^* \in \mathbb{R}^{n\times k}$, and choose $S_i \in \mathbb{R}^{n^{q-1}\times s_i}$ to be a Gaussian sketching matrix with $s_i = O(k/\epsilon)$. We define $Z_i \in \mathbb{R}^{k\times n^{q-1}}$ to be $(\widehat{U}_1^\top \odot \cdots \odot \widehat{U}_{i-1}^\top \odot U_{i+1}^{*\top} \odot \cdots \odot U_q^{*\top})$. We define $\widehat{U}_i$ to be $A_i S_i (Z_i S_i)^\dagger \in \mathbb{R}^{n\times k}$. Then, we have

$$\|\widehat{U}_1 \otimes \cdots \otimes \widehat{U}_{i-1} \otimes \widehat{U}_i \otimes U_{i+1}^* \otimes \cdots \otimes U_q^* - A\|_F^2 \leq (1+\epsilon)^2\,\mathrm{OPT}\,.$$

At the end of the q-th round, we have

$$\|\widehat{U}_1 \otimes \cdots \otimes \widehat{U}_q - A\|_F^2 \leq (1+\epsilon)^q\,\mathrm{OPT}\,.$$

Replacing $\epsilon = \epsilon'/(2q)$, we obtain

$$\|\widehat{U}_1 \otimes \cdots \otimes \widehat{U}_q - A\|_F^2 \leq (1+\epsilon')\,\mathrm{OPT}\,.$$

where for all $i \in [q]$, $s_i = O(kq/\epsilon') = O_q(k/\epsilon')$.

21.5.3 General input sparsity reduction

This section shows how to extend the input sparsity reduction from third order tensors to general q-th order tensors. Given a tensor $A \in \mathbb{R}^{n \times n \times \cdots \times n}$ and q matrices, for each $i \in [q]$, matrix V_i has size $V_i \in \mathbb{R}^{n \times b_i}$, with $b_i \leq \mathrm{poly}(k, 1/\epsilon)$. We choose a batch of sparse embedding matrices $T_i \in \mathbb{R}^{t_i \times n}$. Define $\widehat{V}_i = T_i V_i$, and $C = A(T_1, T_2, \cdots, T_q)$. Thus we have with probability 99/100, for any $\alpha \geq 0$, for all $\{X_i, X_i' \in \mathbb{R}^{b_i \times k}\}_{i \in [q]}$, if

$$\|\widehat{V}_1 X_1' \otimes \widehat{V}_2 X_2' \otimes \cdots \otimes \widehat{V}_q X_q' - C\|_F^2 \leq \alpha \|\widehat{V}_1 X_1 \otimes \widehat{V}_2 X_2 \otimes \cdots \otimes \widehat{V}_q X_q - C\|_F^2,$$

then

$$\|V_1 X_1' \otimes V_2 X_2' \otimes \cdots \otimes V_q X_q' - A\|_F^2 \leq (1+\epsilon)\alpha \|V_1 X_1 \otimes V_2 X_2 \otimes \cdots \otimes V_q X_q - A\|_F^2,$$

where $t_i = O_q(\mathrm{poly}(b_i, 1/\epsilon))$.

Algorithm 21.17 General q-th Order Input Sparsity Reduction

procedure GeneralInputSparsityReduction($A, \{V_i\}_{i \in [q]}, n, k, q, \epsilon$) ▷ Section 21.5.3
  for $i = 1 \to q$ **do**
    Choose sketching matrix $T_i \in \mathbb{R}^{t_i \times n}$ with $t_i = \mathrm{poly}(k, q, 1/\epsilon)$.
    $\widehat{V}_i \leftarrow T_i V_i$.
  end for
  $C \leftarrow A(T_1, T_2, \cdots, T_q)$.
  return $\{\widehat{V}_i\}_{i \in [q]}, C$.
end procedure

21.5.4 Bicriteria algorithm

This section explains how to extend the bicriteria algorithm from third order tensors (Section 21.4.4) to general q-th order tensors. Given any q-th order tensor $A \in \mathbb{R}^{n \times n \times \cdots \times n}$, we can output a rank-$r$ tensor (or equivalently q matrices $U_1, U_2, \cdots, U_q \in \mathbb{R}^{n \times r}$) such that,

$$\|U_1 \otimes U_2 \otimes \cdots \otimes U_q - A\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT},$$

where $r = O_q((k/\epsilon)^{q-1})$ and the algorithm takes $O_q(\mathrm{nnz}(A) + n \cdot \mathrm{poly}(k, 1/\epsilon))$.

Algorithm 21.18 General q-th Order Bicriteria Algorithm

procedure GeneralBicriteriaAlgorithm(A, n, k, q, ϵ) ▷ Section 21.5.4
  for $i = 2 \to q$ **do**
    Choose sketching matrix $S_i \in \mathbb{R}^{n^{q-1} \times s_i}$ with $s_i = O(kq/\epsilon)$.
    Choose sketching matrix $T_i \in \mathbb{R}^{t_i \times n}$ with $t_i = \mathrm{poly}(k, q, 1/\epsilon)$.
    Form matrix $\widehat{U}_i$ by setting $(j_2, j_3, \cdots, j_q)$-th column to be $(A_i S_i)_{j_i}$.
  end for
  Solve $\min_{U_1} \|U_1 B - (A(I, T_2, \cdots, T_q))_1\|_F^2$.
  return $\{\widehat{U}_i\}_{i \in [q]}$.
end procedure

21.5.5 CURT decomposition

This section extends the tensor CURT algorithm from 3rd order tensors (Section 21.4.7) to general q-th order tensors. Given a q-th order tensor $A \in \mathbb{R}^{n \times n \times \cdots \times n}$ and a batch of matrices $U_1, U_2, \cdots, U_q \in \mathbb{R}^{n \times k}$, we iteratively apply the proof in Theorem 21.4.39 (or Theorem 21.4.40) q times. Then for each $i \in [q]$, we are able to select d_i columns from the i-th dimension of tensor A (let C_i denote those columns) and also find a tensor $U \in \mathbb{R}^{d_1 \times d_2 \times \cdots \times d_q}$ such that,

$$\|U(C_1, C_2, \cdots, C_q) - A\|_F^2 \leq (1+\epsilon)\|U_1 \otimes U_2 \otimes \cdots \otimes U_q - A\|_F^2,$$

where either $d_i = O_q(k \log k + k/\epsilon)$ (similar to Theorem 21.4.39) or $d_i = O_q(k/\epsilon)$ (similar to Theorem 21.4.40).

Algorithm 21.19 General q-th Order CURT Decomposition

procedure GeneralCURTDecomposition($A, \{U_i\}_{i\in[q]}, n, k, q, \epsilon$) ▷ Section 21.5.5
  for $i = 1 \to q$ **do**
    Form $B_i = \bigodot_{j<i} \widehat{U}_j^\top \odot \bigodot_{j>i} U_j^\top \in \mathbb{R}^{k \times n^{q-1}}$.
    if fast = true **then** ▷ Optimal running time
      $\epsilon_0 \leftarrow 0.01$.
      $d_i \leftarrow O_q(k \log k + k/\epsilon)$.
      $D_i \leftarrow$ FastTensorLeverageScoreGeneralOrder $(\{\widehat{U}_j\}_{j<i}, \{U_j\}_{j>i}, n, k, \epsilon_0, d_i)$. ▷ Algorithm 21.15
    else ▷ Optimal sample complexity
      $\epsilon_0 \leftarrow O_q(\epsilon)$.
      $D_i \leftarrow$ GeneralizedMatrixRowSubsetSelection $(A_i^\top, B_i^\top, n^{q-1}, n, k, \epsilon_0)$. ▷ Algorithm 21.4.5, $d_i = O_q(k/\epsilon)$.
    end if
    $\widehat{U}_i \leftarrow A_i D_i (B_i D_i)^\dagger$.
    $C_i \leftarrow A_i D_i$.
  end for
  $U \leftarrow (B_1 D_1)^\dagger \otimes (B_2 D_2)^\dagger \otimes \cdots \otimes (B_q D_q)^\dagger$.
  return $\{C_i\}_{i\in[q]}, U$.
end procedure

21.6 Matrix CUR decomposition

There is a long line of research on matrix CUR decomposition under operator, Frobenius or recently, entry-wise ℓ_1 norm [DMM08, BMD09, DR10, BDM11, BW14, SWZ17]. We provide the first algorithm that runs in $\text{nnz}(A)$ time, which improves the previous best matrix CUR decomposition algorithm under Frobenius norm [BW14].

21.6.1 Algorithm

Algorithm 21.20 Optimal Matrix CUR Decomposition Algorithm

procedure OPTIMALMATRIXCUR(A, n, k, ϵ) ▷ Theorem 21.6.1
  $\epsilon' \leftarrow 0.1\epsilon$. $\epsilon'' \leftarrow 0.001\epsilon'$.
  $\widehat{U} \leftarrow$SPARSESVD(A, k, ϵ'). ▷ $\widehat{U} \in \mathbb{R}^{n \times k}$
  Choose $S_1 \in \mathbb{R}^{n \times n}$ to be a sampling and rescaling diagonal matrix according to the leverage scores of $\widehat{U}$ with $s_1 = O(\epsilon^{-2} k \log k)$ nonzero entries.
  $R, Y \leftarrow$GENERALIZEDMATRIXROWSUBSETSELECTION$(S_1 A, S_1 \widehat{U}, s_1, n, k, \epsilon'')$. ▷ Algorithm 21.7, $R \in \mathbb{R}^{r \times n}, Y \in \mathbb{R}^{k \times r}$ and $r = O(k/\epsilon)$
  $\widehat{V} \leftarrow YR \in \mathbb{R}^{k \times n}$.
  Choose $S_2^\top \in \mathbb{R}^{n \times n}$ to be a sampling and rescaling diagonal matrix according to the leverage scores of $\widehat{V}^\top \in \mathbb{R}^{n \times k}$ with $s_2 = O(\epsilon^{-2} k \log k)$ nonzero entries.
  $C^\top, Z^\top \leftarrow$ GENERALIZEDMATRIXROWSUBSETSELECTION $((AS_2)^\top, (\widehat{V} S_2)^\top, s_2, n, k, \epsilon'')$. ▷ Algorithm 21.7, $C \in \mathbb{R}^{n \times c}, Z \in \mathbb{R}^{c \times k}$, and $c = O(k/\epsilon)$
  $U \leftarrow ZY$. ▷ $U \in \mathbb{R}^{c \times r}$ and $\mathrm{rank}(U) = k$
  return C, U, R.
end procedure

Theorem 21.6.1. *Given matrix $A \in \mathbb{R}^{n \times n}$, for any $k \geq 1$ and $\epsilon \in (0, 1)$, there exists an algorithm that takes $O(\mathrm{nnz}(A) + n\,\mathrm{poly}(k, 1/\epsilon))$ time and outputs three matrices $C \in \mathbb{R}^{n \times c}$ with c columns from A, $R \in \mathbb{R}^{r \times n}$ with r rows from A, and $U \in \mathbb{R}^{c \times r}$ with $\mathrm{rank}(U) = k$ such that $r = c = O(k/\epsilon)$ and,*

$$\|CUR - A\|_F^2 \leq (1 + \epsilon) \min_{\mathrm{rank}-k\ A_k} \|A_k - A\|_F^2,$$

holds with probability at least $9/10$.

Proof. We define

$$\mathrm{OPT} = \min_{\mathrm{rank}-k\ A_k} \|A_k - A\|_F^2.$$

We first compute $\widehat{U} \in \mathbb{R}^{n \times k}$ by using the result of [CW13], so that $\widehat{U}$ satisfies:

$$\min_{X \in \mathbb{R}^{k \times n}} \|\widehat{U} X - A\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}\,. \tag{21.25}$$

This step can be done in $O(\mathrm{nnz}(A) + n\,\mathrm{poly}(k, 1/\epsilon))$ time.

We choose $S_1 \in \mathbb{R}^{n \times n}$ to be a sampling and rescaling diagonal matrix according to the leverage scores of $\widehat{U}$, where here $s_1 = O(\epsilon^{-2} k \log k)$ is the number of samples. This step also can be done in $O(n\,\mathrm{poly}(k, 1/\epsilon))$ time.

We run GeneralizedMatrixRowSubsetSelection(Algorithm 21.7) on matrices $S_1 A$ and $S_1 \widehat{U}$. Then we obtain two new matrices R and Y, where R contains $r = O(k/\epsilon)$ rows of $S_1 A$ and Y has size $k \times r$. According to Theorem 21.4.14 and Corollary 21.4.15, this step takes $n\,\mathrm{poly}(k, 1/\epsilon)$ time.

We construct $\widehat{V} = YR$, and choose $S_2^\top$ to be another sampling and rescaling diagonal matrix according to the leverage scores of $\widehat{V}^\top$ with $s_2 = O(\epsilon^{-2} k \log k)$ nonzero entries. As in the case of constructing S_1, this step can be done in $O(n\,\mathrm{poly}(k, 1/\epsilon))$ time.

We run GeneralizedMatrixRowSubsetSelection(Algorithm 21.7) on matrices $(AS_2)^\top$ and $(\widehat{V} S_2)^\top$. Then we can obtain two new matrices $C^\top$ and $Y^\top$, where $C^\top$ contains $c = O(k/\epsilon)$ rows of $(AS_2)^\top$ and $Z^\top$ has size $k \times c$. According to Theorem 21.4.14 and Corollary 21.4.15, this step takes $n\,\mathrm{poly}(k, 1/\epsilon)$ time.

Thus, overall the running time is $O(\mathrm{nnz}(A) + n\,\mathrm{poly}(k, 1/\epsilon))$.

Correctness. Let

$$X^* = \arg \min_{X \in \mathbb{R}^{n \times k}} \|X \widehat{V} - A\|_F^2.$$

According to Corollary 21.4.15,

$$\|CZ\widehat{V}S_2 - AS_2\|_F^2 \leq (1+\epsilon'') \min_{X\in\mathbb{R}^{n\times k}} \|X\widehat{V}S_2 - AS_2\|_F^2 \leq (1+\epsilon'')\|X^*\widehat{V}S_2 - AS_2\|_F^2.$$

According to Theorem 21.6.5, $\epsilon'' = 0.001\epsilon'$,

$$\|CZ\widehat{V} - A\|_F^2 \leq (1+\epsilon')\|X^*\widehat{V} - A\|_F^2. \tag{21.26}$$

Let

$$\widetilde{X} = \arg\min_{X\in\mathbb{R}^{k\times n}} \|\widehat{U}X - A\|_F^2.$$

According to Corollary 21.4.15,

$$\|S_1\widehat{U}YR - S_1A\|_F^2 \leq (1+\epsilon'') \min_{X\in\mathbb{R}^{k\times n}} \|S_1\widehat{U}X - S_1A\|_F^2 \leq (1+\epsilon'')\|S_1\widehat{U}\widetilde{X} - S_1A\|_F^2.$$

According to Theorem 21.6.5, since $\epsilon'' = 0.001\epsilon'$,

$$\|\widehat{U}YR - A\|_F^2 \leq (1+\epsilon')\|\widehat{U}\widetilde{X} - A\|_F^2. \tag{21.27}$$

Then, we can conclude

$$\begin{aligned}
\|CUR - A\|_F^2 &= \|CZYR - A\|_F^2 \\
&= \|CZ\widehat{V} - A\|_F^2 \\
&\leq (1+\epsilon') \min_{X\in\mathbb{R}^{n\times k}} \|X\widehat{V} - A\|_F^2 \\
&\leq (1+\epsilon')\|\widehat{U}\widehat{V} - A\|_F^2 \\
&\leq (1+\epsilon')^2 \min_{X\in\mathbb{R}^{k\times n}} \|\widehat{U}X - A\|_F^2 \\
&\leq (1+\epsilon')^3\,\mathrm{OPT} \\
&\leq (1+\epsilon)\,\mathrm{OPT}\,.
\end{aligned}$$

The first equality follows since $U = ZY$. The second equality follows since $YR = \widehat{V}$. The first inequality follows by Equation (21.26). The third inequality follows by Equation (21.27). The fourth inequality follows by Equation (21.25). The last inequality follows since $\epsilon' = 0.1\epsilon$.

Notice that C has $O(k/\epsilon)$ reweighted columns of AS_2, and AS_2 is a subset of reweighted columns of A, so C has $O(k/\epsilon)$ reweighted columns of A. Similarly, we can prove that R has $O(k/\epsilon)$ reweighted rows of A. Thus, CUR is a CUR decomposition of A.

□

21.6.2 Stronger property achieved by leverage scores

Claim 21.6.2. *Given matrix $A \in \mathbb{R}^{n\times m}$, for any distribution $p = (p_1, p_2, \cdots, p_n)$ define random variable X such that $X = \|A_i\|_2^2/p_i$ with probability p_i, where A_i is the i-th row of matrix A. Then take m independent samples $X^1, X^2, \cdots, X^m$, and let $Y = \frac{1}{m}\sum_{j=1}^m X^j$. We have*

$$\Pr[Y \leq 100\|A\|_F^2] \geq .99.$$

Proof. We can compute the expectation of X^j, for any $j \in [m]$,

$$\mathbb{E}[X^j] = \sum_{i=1}^n \frac{\|A_i\|_2^2}{p_i} \cdot p_i = \|A\|_F^2.$$

Then $\mathbb{E}[Y] = \frac{1}{m}\sum_{j=1}^m \mathbb{E}[X^j] = \|A\|_F^2$. Using Markov's inequality, we have

$$\Pr[Y \geq \|A\|_F^2] \leq .01.$$

□

Theorem 21.6.3 (The leverage score case of Theorem 39 in [CW13])**.** *Let $A \in \mathbb{R}^{n\times k}$, $B \in \mathbb{R}^{n\times d}$. Let $S \in \mathbb{R}^{n\times n}$ denote a sampling and rescaling diagonal matrix according to the leverage scores of A. If the event occurs that S satisfies $(\epsilon/\sqrt{k})$-Frobenius norm approximate matrix product for A, and also S is a $(1+\epsilon)$-subspace embedding for A, then let X^* be the optimal solution of $\min_X \|AX - B\|_F^2$, and $\widetilde{B} \equiv AX^* - B$. Then, for all $X \in \mathbb{R}^{k\times d}$,*

$$(1-2\epsilon)\|AX - B\|_F^2 \leq \|S(AX - B)\|_F^2 + \|\widetilde{B}\|_F^2 - \|S\widetilde{B}\|_F^2 \leq (1+2\epsilon)\|AX - B\|_F^2.$$

Furthermore, if S has $m = O(\epsilon^{-2}k\log(k))$ nonzero entries, the above event happens with probability at least 0.99.

Note that Theorem 39 in [CW13] is stated in a way that holds for general sketching matrices. However, we are only interested in the case when S is a sampling and rescaling diagonal matrix according to the leverage scores. For completeness, we provide the full proof of the leverage score case with certain parameters.

Proof. Suppose S is a sampling and rescaling diagonal matrix according to the leverage scores of A, and it has $m = O(\epsilon^{-2} k \log k)$ nonzero entries. Then, according to Lemma 21.4.22, S is a $(1+\epsilon)$-subspace embedding for A with probability at least 0.999, and according to Lemma 21.4.29, S satisfies $(\epsilon/\sqrt{k})$-Frobenius norm approximate matrix product for A with probability at least 0.999.

Let $U \in \mathbb{R}^{n \times k}$ denote an orthonormal basis of the column span of A. Then the leverage scores of U are the same as the leverage scores of A. Furthermore, for any $X \in \mathbb{R}^{k \times d}$, there is a matrix Y such that $AX = UY$, and vice versa, so we can now assume A has k orthonormal columns.

Then,

$$\begin{aligned}
&\|S(AX - B)\|_F^2 - \|S\widetilde{B}\|_F^2 \\
&= \|SA(X - X^*) + S(AX^* - B)\|_F^2 - \|S\widetilde{B}\|_F^2 \\
&= \|SA(X - X^*)\|_F^2 + \|S(AX^* - B)\|_F^2 + 2\operatorname{tr}\left((X - X^*)^\top A^\top S^\top S(AX^* - B)\right) - \|S\widetilde{B}\|_F^2 \\
&= \underbrace{\|SA(X - X^*)\|_F^2 + 2\operatorname{tr}\left((X - X^*)^\top A^\top S^\top S\widetilde{B}\right)}_{\alpha}. \qquad (21.28)
\end{aligned}$$

The second equality follows using $\|C+D\|_F^2 = \|C\|_F^2 + \|D\|_F^2 + 2\operatorname{tr}(C^\top D)$. The third equality

follows from $\widetilde{B} = AX^* - B$. Now, let us first upper bound the term α in Equation (21.28):

$$\begin{aligned}
&\|SA(X - X^*)\|_F^2 + 2\,\mathrm{tr}\left((X - X^*)^\top A^\top S^\top S\widetilde{B}\right) \\
&\leq (1+\epsilon)\|A(X - X^*)\|_F^2 + 2\|X - X^*\|_F\|A^\top S^\top S\widetilde{B}\|_F \\
&\leq (1+\epsilon)\|A(X - X^*)\|_F^2 + 2(\epsilon/\sqrt{k}) \cdot \|X - X^*\|_F\|A\|_F\|\widetilde{B}\|_F \\
&\leq (1+\epsilon)\|A(X - X^*)\|_F^2 + 2\epsilon\|A(X - X^*)\|_F\|\widetilde{B}\|_F.
\end{aligned}$$

The first inequality follows since S is a $(1+\epsilon)$ subspace embedding of A, and $\mathrm{tr}(C^\top D) \leq \|C\|_F\|D\|_F$. The second inequality follows since S satisfies $(\epsilon/\sqrt{k})$-Frobenius norm approximate matrix product for A. The last inequality follows using that $\|A\|_F \leq \sqrt{k}$ since A only has k orthonormal columns. Now, let us lower bound the term α in Equation (21.28):

$$\begin{aligned}
&\|SA(X - X^*)\|_F^2 + 2\,\mathrm{tr}\left((X - X^*)^\top A^\top S^\top S\widetilde{B}\right) \\
&\geq (1-\epsilon)\|A(X - X^*)\|_F^2 - 2\|X - X^*\|_F\|A^\top S^\top S\widetilde{B}\|_F \\
&\geq (1-\epsilon)\|A(X - X^*)\|_F^2 - 2(\epsilon/\sqrt{k}) \cdot \|X - X^*\|_F\|A\|_F\|\widetilde{B}\|_F \\
&\geq (1-\epsilon)\|A(X - X^*)\|_F^2 - 2\epsilon\|A(X - X^*)\|_F\|\widetilde{B}\|_F.
\end{aligned}$$

The first inequality follows since S is a $(1+\epsilon)$ subspace embedding of A, and $\mathrm{tr}(C^\top D) \geq -\|C\|_F\|D\|_F$. The second inequality follows since S satisfies $(\epsilon/\sqrt{k})$-Frobenius norm approximate matrix product for A. The last inequality follows using that $\|A\|_F \leq \sqrt{k}$ since A only has k orthonormal columns.

Therefore,

$$(1-\epsilon)\|A(X - X^*)\|_F^2 - 2\epsilon\|A(X - X^*)\|_F\|\widetilde{B}\|_F \leq \|S(AX - B)\|_F^2 - \|S\widetilde{B}\|_F^2, \qquad (21.29)$$

and

$$(1+\epsilon)\|A(X-X^*)\|_F^2 + 2\epsilon\|A(X-X^*)\|_F\|\widetilde{B}\|_F \geq \|S(AX-B)\|_F^2 - \|S\widetilde{B}\|_F^2. \tag{21.30}$$

Notice that $\widetilde{B} = AX^* - B = AA^\dagger B - B = (AA^\dagger - I)B$, so according to the Pythagorean theorem, we have

$$\|AX-B\|_F^2 = \|A(X-X^*)\|_F^2 + \|\widetilde{B}\|_F^2,$$

which means that

$$\|A(X-X^*)\|_F^2 = \|AX-B\|_F^2 - \|\widetilde{B}\|_F^2. \tag{21.31}$$

Using Equation (21.31), we can rewrite and lower bound the LHS of Equation (21.29),

$$\begin{aligned}
&(1-\epsilon)\|A(X-X^*)\|_F^2 - 2\epsilon\|A(X-X^*)\|_F\|\widetilde{B}\|_F \\
&= \|A(X-X^*)\|_F^2 - \epsilon\left(\|A(X-X^*)\|_F^2 + 2\|A(X-X^*)\|_F\|\widetilde{B}\|_F\right) \\
&= \|AX-B\|_F^2 - \|\widetilde{B}\|_F^2 - \epsilon\left(\|A(X-X^*)\|_F^2 + 2\|A(X-X^*)\|_F\|\widetilde{B}\|_F\right) \\
&\geq \|AX-B\|_F^2 - \|\widetilde{B}\|_F^2 - \epsilon\left(\|A(X-X^*)\|_F + \|\widetilde{B}\|_F\right)^2 \\
&\geq \|AX-B\|_F^2 - \|\widetilde{B}\|_F^2 - 2\epsilon\left(\|A(X-X^*)\|_F^2 + \|\widetilde{B}\|_F^2\right) \\
&= (1-2\epsilon)\|AX-B\|_F^2 - \|\widetilde{B}\|_F^2.
\end{aligned} \tag{21.32}$$

The second step follows by Equation (21.31). The first inequality follows using $a^2 + 2ab < (a+b)^2$. The second inequality follows using $(a+b)^2 \leq 2(a^2+b^2)$. The last equality follows using $\|A(X-X^*)\|_F^2 + \|\widetilde{B}\|_F^2 = \|AX-B\|_F^2$. Similarly, using Equation (21.31), we can rewrite and upper bound the LHS of Equation (21.30)

$$(1+\epsilon)\|A(X-X^*)\|_F^2 + 2\epsilon\|A(X-X^*)\|_F\|\widetilde{B}\|_F \leq (1+2\epsilon)\|AX-B\|_F^2 - \|\widetilde{B}\|_F^2. \tag{21.33}$$

Combining Equations (21.29),(21.32),(21.30),(21.33), we conclude that

$$(1-2\epsilon)\|AX-B\|_F^2 - \|\widetilde{B}\|_F^2 \leq \|S(AX-B)\|_F^2 - \|S\widetilde{B}\|_F^2 \leq (1+2\epsilon)\|AX-B\|_F^2 - \|\widetilde{B}\|_F^2.$$

□

Theorem 21.6.4. *Let $A \in \mathbb{R}^{n\times k}$, $B \in \mathbb{R}^{n\times d}$, and $\frac{1}{2} > \epsilon > 0$. Let X^* be the optimal solution to $\min_X \|AX-B\|_F^2$, and $\widetilde{B} \equiv AX^* - B$. Let $S \in \mathbb{R}^{n\times n}$ denote a sketching matrix which satisfies the following:*

1. $\|S\widetilde{B}\|_F^2 \leq 100 \cdot \|\widetilde{B}\|_F^2$,
2. *for all $X \in \mathbb{R}^{k\times d}$,*

$$(1-\epsilon)\|AX-B\|_F^2 \leq \|S(AX-B)\|_F^2 + \|\widetilde{B}\|_F^2 - \|S\widetilde{B}\|_F^2 \leq (1+\epsilon)\|AX-B\|_F^2.$$

Then, for all $X_1, X_2 \in \mathbb{R}^{k\times d}$ satisfying

$$\|SAX_1 - SB\|_F^2 \leq \left(1+\frac{\epsilon}{100}\right) \cdot \|SAX_2 - SB\|_F^2,$$

we have

$$\|AX_1 - B\|_F^2 \leq (1+5\epsilon) \cdot \|AX_2 - B\|_F^2.$$

Proof. Let A, B, S, ϵ be the same as in the statement of the theorem, and suppose S satisfies those two conditions. Let $X_1, X_2 \in \mathbb{R}^{k\times d}$ satisfy

$$\|SAX_1 - SB\|_F^2 \leq \left(1+\frac{\epsilon}{100}\right) \|SAX_2 - SB\|_F^2.$$

We have

$$\begin{aligned}
&\|AX_1 - B\|_F^2 \\
&\leq \frac{1}{1-\epsilon}\left(\|S(AX_1 - B)\|_F^2 + \|\widetilde{B}\|_F^2 - \|S\widetilde{B}\|_F^2\right) \\
&\leq \frac{1}{1-\epsilon}\left(\left(1+\frac{\epsilon}{100}\right)\cdot\|S(AX_2 - B)\|_F^2 + \|\widetilde{B}\|_F^2 - \|S\widetilde{B}\|_F^2\right) \\
&= \frac{1}{1-\epsilon}\left(\left(1+\frac{\epsilon}{100}\right)\cdot\left(\|S(AX_2 - B)\|_F^2 + \|\widetilde{B}\|_F^2 - \|S\widetilde{B}\|_F^2\right) - \frac{\epsilon}{100}\cdot\left(\|\widetilde{B}\|_F^2 - \|S\widetilde{B}\|_F^2\right)\right) \\
&\leq \frac{1}{1-\epsilon}\cdot\left(1+\frac{\epsilon}{100}\right)\cdot\|AX_2 - B\|_F^2 - \frac{1}{1-\epsilon}\cdot\frac{\epsilon}{100}\cdot\left(\|\widetilde{B}\|_F^2 - \|S\widetilde{B}\|_F^2\right) \\
&\leq (1+3\epsilon)\|AX_2 - B\|_F^2 + \frac{1}{1-\epsilon}\cdot\frac{\epsilon}{100}\|S\widetilde{B}\|_F^2 \\
&\leq (1+3\epsilon)\|AX_2 - B\|_F^2 + 2\epsilon\|\widetilde{B}\|_F^2 \\
&\leq (1+5\epsilon)\|AX_2 - B\|_F^2.
\end{aligned}$$

The first inequality follows since S satisfies the second condition. The second inequality follows by the relationship between X_1 and X_2. The third inequality follows since S satisfies the second condition. The fifth inequality follows using that $\epsilon < \frac{1}{2}$ and that S satisfies the first condition. The last inequality follows using that $\|\widetilde{B}\|_F^2 = \|AX^* - B\|_F^2 \leq \|AX_2 - B\|_F^2$. □

Theorem 21.6.5. *Let $A \in \mathbb{R}^{n\times k}$, $B \in \mathbb{R}^{n\times d}$, and $\frac{1}{2} > \epsilon > 0$. Let $S \in \mathbb{R}^{n\times n}$ denote a sampling and rescaling diagonal matrix according to the leverage scores of A. If S has at least $m = O(k\log(k)/\epsilon^2)$ nonzero entries, then with probability at least 0.98, for all $X_1, X_2 \in \mathbb{R}^{k\times d}$ satisfying*

$$\|SAX_1 - SB\|_F^2 \leq (1+\frac{\epsilon}{500})\cdot\|SAX_2 - SB\|_F^2,$$

we have

$$\|AX_1 - B\|_F^2 \leq (1+\epsilon)\cdot\|AX_2 - B\|_F^2.$$

Proof. The proof directly follows by Claim 21.6.2, Theorem 21.6.3 and Theorem 21.6.4. Because of Claim 21.6.2, S satisfies the first condition in the statement of Theorem 21.6.4 with probability at least 0.99. According to Theorem 21.6.3, S satisfies the second condition in the statement of Theorem 21.6.4 with probability at least 0.99. Thus, with probability 0.98, by Theorem 21.6.4, we complete the proof. □

21.7 Entry-wise ℓ_1 Norm for Arbitrary Tensors

In this section, we provide several different algorithms for tensor ℓ_1-low rank approximation. Section 21.7.1 provides some useful facts and definitions. Section 21.7.2 presents several existence results. Section 21.7.3 describes a tool that is able to reduce the size of the objective function from poly(n) to poly(k). Section 21.7.4 discusses the case when the problem size is small. Section 21.7.5 provides several bicriteria algorithms. Section 21.7.6 summarizes a batch of algorithms. Section 21.7.7 provides an algorithm for ℓ_1 norm CURT decomposition.

Notice that if the rank $-k$ solution does not exist, then every bicriteria algorithm in Section 21.7.5 can be stated in a form similar to Theorem 21.1.1, and every algorithm which can output a rank $-k$ solution in Section 21.7.6 can be stated in a form similar to Theorem 21.1.2. See Section 21.1 for more details.

21.7.1 Facts

We present a method that is able to reduce the entry-wise ℓ_1-norm objective function to the Frobenius norm objective function.

Fact 21.7.1. *Given a 3rd order tensor $C \in \mathbb{R}^{c_1 \times c_2 \times c_3}$, three matrices $V_1 \in \mathbb{R}^{c_1 \times b_1}$, $V_2 \in \mathbb{R}^{c_2 \times b_2}$, $V_3 \in \mathbb{R}^{c_3 \times b_3}$, for any $k \in [1, \min_i b_i]$, if $X_1' \in \mathbb{R}^{b_1 \times k}, X_2' \in \mathbb{R}^{b_2 \times k}, X_3' \in \mathbb{R}^{b_3 \times k}$ satisfies that,*

$$\|(V_1 X_1') \otimes (V_2 X_2') \otimes (V_3 X_3') - C\|_F \leq \alpha \min_{X_1, X_2, X_3} \|(V_1 X_1) \otimes (V_2 X_2) \otimes (V_3 X_3) - C\|_F,$$

then

$$\|(V_1 X_1') \otimes (V_2 X_2') \otimes (V_3 X_3') - C\|_1 \leq \alpha \sqrt{c_1 c_2 c_3} \min_{X_1, X_2, X_3} \|(V_1 X_1) \otimes (V_2 X_2) \otimes (V_3 X_3) - C\|_1.$$

We extend Lemma C.15 in [SWZ17] to tensors:

Fact 21.7.2. *Given tensor $A \in \mathbb{R}^{n \times n \times n}$, let $\mathrm{OPT} = \min_{\mathrm{rank}-k\ A_k} \|A - A_k\|_1$. For any $r \geq k$, if* rank-r *tensor $B \in \mathbb{R}^{n \times n \times n}$ is an f-approximation to A, i.e.,*

$$\|B - A\|_1 \leq f \cdot \mathrm{OPT},$$

and $U, V, W \in \mathbb{R}^{n \times k}$ is a g-approximation to B, i.e.,

$$\|U \otimes V \otimes W - B\|_1 \leq g \cdot \min_{\mathrm{rank}-k\ B_k} \|B_k - B\|_1,$$

then,

$$\|U \otimes V \otimes W - A\|_1 \lesssim gf \cdot \mathrm{OPT}\,.$$

Proof. We define $\widetilde{U}, \widetilde{V}, \widetilde{W} \in \mathbb{R}^{n\times k}$ to be three matrices, such that

$$\|\widetilde{U} \otimes \widetilde{V} \otimes \widetilde{W} - B\|_1 \leq g \min_{\mathrm{rank}-k\ B_k} \|B_k - B\|_1,$$

and also define,

$$\widehat{U}, \widehat{V}, \widehat{W} = \arg\min_{U,V,W\in\mathbb{R}^{n\times k}} \|U \otimes V \otimes W - B\|_1 \text{ and } U^*, V^*, W^* = \arg\min_{U,V,W\in\mathbb{R}^{n\times k}} \|U \otimes V \otimes W - A\|_1.$$

It is obvious that,

$$\|\widehat{U} \otimes \widehat{V} \otimes \widehat{W} - B\|_1 \leq \|U^* \otimes V^* \otimes W^* - B\|_1. \tag{21.34}$$

Then,

$$\begin{aligned}
&\|\widetilde{U} \otimes \widetilde{V} \otimes \widetilde{W} - A\|_1 \\
&\leq \|\widetilde{U} \otimes \widetilde{V} \otimes \widetilde{W} - B\|_1 + \|B - A\|_1 && \text{by the triangle inequality} \\
&\leq g\|\widehat{U} \otimes \widehat{V} \otimes \widehat{W} - B\|_1 + \|B - A\|_1 && \text{by definition} \\
&\leq g\|U^* \otimes V^* \otimes W^* - B\|_1 + \|B - A\|_1 && \text{by Equation (21.34)} \\
&\leq g\|U^* \otimes V^* \otimes W^* - A\|_1 + g\|B - A\|_1 + \|B - A\|_1 && \text{by the triangle inequality} \\
&= g\,\mathrm{OPT} + (g+1)\|B - A\|_1 && \text{by definition of OPT} \\
&\leq g\,\mathrm{OPT} + (g+1)f \cdot \mathrm{OPT} && \text{since } B \text{ is an } f\text{-approximation to } A \\
&\lesssim gf\,\mathrm{OPT}\,.
\end{aligned}$$

This completes the proof. □

Using the above fact, we are able to optimize our approximation ratio.

21.7.2 Existence results

Definition 21.7.1 (ℓ_1 multiple regression cost preserving sketch - Definition D.5 in [SWZ17])**.** Given matrices $U \in \mathbb{R}^{n\times r}, A \in \mathbb{R}^{n\times d}$, let $S \in \mathbb{R}^{m\times n}$. If $\forall \beta \geq 1, \widehat{V} \in \mathbb{R}^{r\times d}$ which satisfy

$$\|SU\widehat{V} - SA\|_1 \leq \beta \cdot \min_{V\in\mathbb{R}^{r\times d}} \|SUV - SA\|_1,$$

it holds that

$$\|U\widehat{V} - A\|_1 \leq \beta \cdot c \cdot \min_{V\in\mathbb{R}^{r\times d}} \|UV - A\|_1,$$

then S provides a c-ℓ_1-multiple-regression-cost-preserving-sketch for (U, A).

Theorem 21.7.3. *Given a 3rd order tensor $A \in \mathbb{R}^{n\times n\times n}$, for any $k \geq 1$, there exist three matrices $S_1 \in \mathbb{R}^{n^2\times s_1}$, $S_2 \in \mathbb{R}^{n^2\times s_2}$, $S_3 \in \mathbb{R}^{n^2\times s_3}$ such that*

$$\min_{X_1,X_2,X_3} \left\| \sum_{i=1}^{k} (A_1S_1X_1)_i \otimes (A_2S_2X_2)_i \otimes (A_3S_3X_3)_i - A \right\|_1 \leq \alpha \min_{\text{rank}-k\ A_k\in\mathbb{R}^{n\times n\times n}} \|A_k - A\|_1,$$

holds with probability 99/100*.*

(I). *Using a dense Cauchy transform,*

$s_1 = s_2 = s_3 = \widetilde{O}(k)$, $\alpha = \widetilde{O}(k^{1.5}) \log^3 n$.

(II). *Using a sparse Cauchy transform,*

$s_1 = s_2 = s_3 = \widetilde{O}(k^5)$, $\alpha = \widetilde{O}(k^{13.5}) \log^3 n$.

(III). *Guessing Lewis weights,*

$s_1 = s_2 = s_3 = \widetilde{O}(k)$, $\alpha = \widetilde{O}(k^{1.5})$.

Proof. We use OPT to denote

$$\text{OPT} := \min_{\text{rank}-k\ A_k\in\mathbb{R}^{n\times n\times n}} \|A_k - A\|_1.$$

Given a tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, we define three matrices $A_1 \in \mathbb{R}^{n_1 \times n_2 n_3}$, $A_2 \in \mathbb{R}^{n_2 \times n_3 n_1}$, $A_3 \in \mathbb{R}^{n_3 \times n_1 n_2}$ such that, for any $i \in [n_1], j \in [n_2], l \in [n_3]$,

$$A_{i,j,l} = (A_1)_{i,(j-1)\cdot n_3 + l} = (A_2)_{j,(l-1)\cdot n_1 + i} = (A_3)_{l,(i-1)\cdot n_2 + j}.$$

We fix $V^* \in \mathbb{R}^{n \times k}$ and $W^* \in \mathbb{R}^{n \times k}$, and use $V_1^*, V_2^*, \cdots, V_k^*$ to denote the columns of V^* and $W_1^*, W_2^*, \cdots, W_k^*$ to denote the columns of W^*.

We consider the following optimization problem,

$$\min_{U_1, \cdots, U_k \in \mathbb{R}^n} \left\| \sum_{i=1}^k U_i \otimes V_i^* \otimes W_i^* - A \right\|_1,$$

which is equivalent to

$$\min_{U_1, \cdots, U_k \in \mathbb{R}^n} \left\| \begin{bmatrix} U_1 & U_2 & \cdots & U_k \end{bmatrix} \begin{bmatrix} V_1^* \otimes W_1^* \\ V_2^* \otimes W_2^* \\ \cdots \\ V_k^* \otimes W_k^* \end{bmatrix} - A \right\|_1.$$

We use matrix Z_1 to denote $V^{*\top} \odot W^{*\top} \in \mathbb{R}^{k \times n^2}$ and matrix U to denote $\begin{bmatrix} U_1 & U_2 & \cdots & U_k \end{bmatrix}$. Then we can obtain the following equivalent objective function,

$$\min_{U \in \mathbb{R}^{n \times k}} \|U Z_1 - A_1\|_1.$$

Choose an ℓ_1 multiple regression cost preserving sketch $S_1 \in \mathbb{R}^{n^2 \times s_1}$ for $(Z_1^\top, A_1^\top)$. We can obtain the optimization problem,

$$\min_{U \in \mathbb{R}^{n \times k}} \|U Z_1 S_1 - A_1 S_1\|_1 = \min_{U \in \mathbb{R}^{n \times k}} \sum_{i=1}^n \|U^i Z_1 S_1 - (A_1 S_1)^i\|_1,$$

where U^i denotes the i-th row of matrix $U \in \mathbb{R}^{n\times k}$ and $(A_1S_1)^i$ denotes the i-th row of matrix A_1S_1. Instead of solving it under the ℓ_1-norm, we consider the ℓ_2-norm relaxation,

$$\min_{U\in\mathbb{R}^{n\times k}} \|UZ_1S_1 - A_1S_1\|_F^2 = \min_{U\in\mathbb{R}^{n\times k}} \sum_{i=1}^{n} \|U^iZ_1S_1 - (A_1S_1)^i\|_2^2.$$

Let $\widehat{U} \in \mathbb{R}^{n\times k}$ denote the optimal solution of the above optimization problem. Then, $\widehat{U} = A_1S_1(Z_1S_1)^\dagger$. We plug $\widehat{U}$ into the objective function under the ℓ_1-norm. According to Claim 21.3.4, we have,

$$\|\widehat{U}Z_1S_1 - A_1S_1\|_1 = \sum_{i=1}^{n} \|\widehat{U}^iZ_1S_1 - (A_1S_1)^i\|_1 \leq \sqrt{s_1} \min_{U\in\mathbb{R}^{n\times k}} \|UZ_1S_1 - A_1S_1\|_1.$$

Since $S_1 \in \mathbb{R}^{n^2\times s_1}$ satisfies Definition 21.7.1, we have

$$\|\widehat{U}Z_1 - A_1\|_1 \leq \alpha \min_{U\in\mathbb{R}^{n\times k}} \|UZ_1 - A_1\|_1 = \alpha\,\mathrm{OPT},$$

where $\alpha = \sqrt{s_1}\beta$ and β (see Definition 21.7.1) is a parameter which depends on which kind of sketching matrix we actually choose. It implies

$$\|\widehat{U} \otimes V^* \otimes W^* - A\|_1 \leq \alpha\,\mathrm{OPT}\,.$$

As a second step, we fix $\widehat{U} \in \mathbb{R}^{n\times k}$ and $W^* \in \mathbb{R}^{n\times k}$, and convert tensor A into matrix A_2. Let matrix Z_2 denote $\widehat{U}^\top \odot W^{*\top}$. We consider the following objective function,

$$\min_{V\in\mathbb{R}^{n\times k}} \|VZ_2 - A_2\|_1,$$

and the optimal cost of it is at most $\alpha\,\mathrm{OPT}$.

Choose an ℓ_1 multiple regression cost preserving sketch $S_2 \in \mathbb{R}^{n^2\times s_2}$ for $(Z_2^\top, A_2^\top)$, and sketch on the right of the objective function to obtain this new objective function,

$$\min_{V\in\mathbb{R}^{n\times k}} \|VZ_2S_2 - A_2S_2\|_1 = \min_{U\in\mathbb{R}^{n\times k}} \sum_{i=1}^{n} \|V^iZ_2S_2 - (A_2S_2)^i\|_1,$$

where V^i denotes the i-th row of matrix V and $(A_2S_2)^i$ denotes the i-th row of matrix A_2S_2. Instead of solving this under the ℓ_1-norm, we consider the ℓ_2-norm relaxation,

$$\min_{U\in\mathbb{R}^{n\times k}}\|VZ_2S_2 - A_2S_2\|_F^2 = \min_{V\in\mathbb{R}^{n\times k}}\|V^i(Z_2S_2) - (A_2S_2)^i\|_2^2.$$

Let $\widehat{V} \in \mathbb{R}^{n\times k}$ denote the optimal solution of the above problem. Then $\widehat{V} = A_2S_2(Z_2S_2)^\dagger$. By properties of the sketching matrix $S_2 \in \mathbb{R}^{n^2\times s_2}$, we have,

$$\|\widehat{V}Z_2 - A_2\|_1 \leq \alpha \min_{V\in\mathbb{R}^{n\times k}}\|VZ_2 - A_2\|_1 \leq \alpha^2\,\mathrm{OPT},$$

which implies

$$\|\widehat{U}\otimes\widehat{V}\otimes W^* - A\|_1 \leq \alpha^2\,\mathrm{OPT}\,.$$

As a third step, we fix the matrices $\widehat{U} \in \mathbb{R}^{n\times k}$ and $\widehat{V} \in \mathbb{R}^{n\times k}$. We can convert tensor $A \in \mathbb{R}^{n\times n\times n}$ into matrix $A_3 \in \mathbb{R}^{n^2\times n}$. Let matrix Z_3 denote $\widehat{U}^\top \odot \widehat{V}^\top \in \mathbb{R}^{k\times n^2}$. We consider the following objective function,

$$\min_{W\in\mathbb{R}^{n\times k}}\|WZ_3 - A_3\|_1,$$

and the optimal cost of it is at most $\alpha^2\,\mathrm{OPT}$.

Choose an ℓ_1 multiple regression cost preserving sketch $S_3 \in \mathbb{R}^{n^2\times s_3}$ for $(Z_3^\top, A_3^\top)$ and sketch on the right of the objective function to obtain the new objective function,

$$\min_{W\in\mathbb{R}^{n\times k}}\|WZ_3S_3 - A_3S_3\|_1.$$

Let $\widehat{W} \in \mathbb{R}^{n\times k}$ denote the optimal solution of the above problem. Then $\widehat{W} = A_3S_3(Z_3S_3)^\dagger$. By properties of sketching matrix $S_3 \in \mathbb{R}^{n^2\times s_3}$, we have,

$$\|\widehat{W}Z_3 - A_3\|_1 \leq \alpha \min_{W\in\mathbb{R}^{n\times k}}\|WZ_3 - A_3\|_1 \leq \alpha^3\,\mathrm{OPT}\,.$$

Thus, we obtain,

$$\min_{X_1\in\mathbb{R}^{s_1\times k},X_2\in\mathbb{R}^{s_2\times k},X_3\in\mathbb{R}^{s_3\times k}}\left\|\sum_{i=1}^{k}(A_1S_1X_1)_i\otimes(A_2S_2X_2)_i\otimes(A_3S_3X_3)_i-A\right\|_1\leq\alpha^3\,\mathrm{OPT}\,.$$

Proof of (I) By Theorem C.1 in [SWZ17], we can use dense Cauchy transforms for S_1, S_2, S_3, and then $s_1 = s_2 = s_3 = O(k\log k)$ and $\alpha = O(\sqrt{k\log k}\log n)$.

Proof of (II) By Theorem C.1 in [SWZ17], we can use sparse Cauchy transforms for S_1, S_2, S_3, and then $s_1 = s_2 = s_3 = O(k^5\log^5 k)$ and $\alpha = O(k^{4.5}\log^{4.5} k\log n)$.

Proof of (III) By Theorem C.1 in [SWZ17], we can sample by Lewis weights. Then $S_1, S_2, S_3 \in \mathbb{R}^{n^2\times n^2}$ are diagonal matrices, and each of them has $O(k\log k)$ nonzero rows. This gives $\alpha = O(\sqrt{k\log k})$.

□

21.7.3 Polynomial in k size reduction

Definition 21.7.2 (Definition D.1 in [SWZ17])**.** Given a matrix $M \in \mathbb{R}^{n\times d}$, if matrix $S \in \mathbb{R}^{m\times n}$ satisfies

$$\|SM\|_1 \le \beta\|M\|_1,$$

then S has at most β dilation on M.

Definition 21.7.3 (Definition D.2 in [SWZ17])**.** Given a matrix $U \in \mathbb{R}^{n\times k}$, if matrix $S \in \mathbb{R}^{m\times n}$ satisfies

$$\forall x \in \mathbb{R}^k, \|SUx\|_1 \ge \frac{1}{\beta}\|Ux\|_1,$$

then S has at most β contraction on U.

Theorem 21.7.4. *Given a tensor $A \in \mathbb{R}^{n_1\times n_2\times n_3}$ and three matrices $V_1 \in \mathbb{R}^{n_1\times b_1}, V_2 \in \mathbb{R}^{n_2\times b_2}, V_3 \in \mathbb{R}^{n_3\times b_3}$, let $X_1^* \in \mathbb{R}^{b_1\times k}, X_2^* \in \mathbb{R}^{b_2\times k}, X_3^* \in \mathbb{R}^{b_3\times k}$ satisfies*

$$X_1^*, X_2^*, X_3^* = \arg\min_{X_1\in\mathbb{R}^{b_1\times k}, X_2\in\mathbb{R}^{b_2\times k}, X_3\in\mathbb{R}^{b_3\times k}} \|V_1X_1 \otimes V_2X_2 \otimes V_3X_3 - A\|_1.$$

Let $S \in \mathbb{R}^{m\times n}$ have at most $\beta_1 \ge 1$ dilation on $V_1X_1^* \cdot ((V_2X_2^*)^\top \odot (V_3X_3^*)^\top) - A_1$ and S have at most $\beta_2 \ge 1$ contraction on V_1. If $\widehat{X}_1 \in \mathbb{R}^{b_1\times k}, \widehat{X}_2 \in \mathbb{R}^{b_2\times k}, \widehat{X}_3 \in \mathbb{R}^{b_3\times k}$ satisfies

$$\|SV_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - SA\|_1 \le \beta \min_{X_1\in\mathbb{R}^{b_1\times k}, X_2\in\mathbb{R}^{b_2\times k}, X_3\in\mathbb{R}^{b_3\times k}} \|SV_1X_1 \otimes V_2X_2 \otimes V_3X_3 - SA\|_1,$$

where $\beta \ge 1$, then

$$\|V_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - A\|_1 \lesssim \beta_1\beta_2\beta \min_{X_1,X_2,X_3} \|V_1X_1 \otimes V_2X_2 \otimes V_3X_3 - A\|_1.$$

The proof idea is similar to [SWZ17].

Proof. Let $A, V_1, V_2, V_3, S, X_1^*, X_2^*, X_3^*, \beta_1, \beta_2$ be the same as stated in the theorem. Let $\widehat{X}_1 \in \mathbb{R}^{b_1 \times k}, \widehat{X}_2 \in \mathbb{R}^{b_2 \times k}, \widehat{X}_3 \in \mathbb{R}^{b_3 \times k}$ satisfy

$$\|SV_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - SA\|_1 \leq \beta \min_{X_1 \in \mathbb{R}^{b_1 \times k}, X_2 \in \mathbb{R}^{b_2 \times k}, X_3 \in \mathbb{R}^{b_3 \times k}} \|SV_1X_1 \otimes V_2X_2 \otimes V_3X_3 - SA\|_1.$$

We have,

$$\begin{aligned}
&\|SV_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - SA\|_1 \\
\geq\ &\|SV_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - SV_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^*\|_1 - \|SV_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - SA\|_1 \\
\geq\ &\frac{1}{\beta_2}\|V_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^*\|_1 - \beta_1\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_1 \\
\geq\ &\frac{1}{\beta_2}\|V_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - A\|_1 - \frac{1}{\beta_2}\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_1 \\
&- \beta_1\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_1 \\
=\ &\frac{1}{\beta_2}\|V_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - A\|_1 - (\frac{1}{\beta_2} + \beta_1)\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_1. \qquad (21.35)
\end{aligned}$$

The first and the third inequality follow by the triangle inequalities. The second inequality follows using that

$$\begin{aligned}
&\|SV_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - SV_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^*\|_1 \\
=\ &\left\|SV_1(\widehat{X}_1 - X_1^*) \cdot \left((V_2(\widehat{X}_2 - X_2^*))^\top \odot (V_3(\widehat{X}_3 - X_3^*))^\top\right)\right\|_1 \\
\geq\ &\frac{1}{\beta_2}\left\|V_1(\widehat{X}_1 - X_1^*) \cdot \left((V_2(\widehat{X}_2 - X_2^*))^\top \odot (V_3(\widehat{X}_3 - X_3^*))^\top\right)\right\|_1 \\
\geq\ &\frac{1}{\beta_2}\|V_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^*\|_1,
\end{aligned}$$

and

$$\begin{aligned}
&\|SV_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - SA\|_1 \\
&= \|S(V_1X_1^* \cdot ((V_2X_2^*)^\top \odot (V_3X_3^*)^\top) - A_1)\|_1 \\
&\leq \|V_1X_1^* \cdot ((V_2X_2^*)^\top \odot (V_3X_3^*)^\top) - A_1\|_1 \\
&= \beta_1\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_1. \qquad (21.36)
\end{aligned}$$

Then, we have

$$\begin{aligned}
&\|V_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - A\|_1 \\
&\leq \beta_2\|SV_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - SA\|_1 + (1+\beta_1\beta_2)\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_1 \\
&\leq \beta_2\beta\|SV_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - SA\|_1 + (1+\beta_1\beta_2)\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_1 \\
&\leq \beta_1\beta_2\beta\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_1 + (1+\beta_1\beta_2)\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_1 \\
&\leq \beta(1+2\beta_1\beta_2)\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_1.
\end{aligned}$$

The first inequality follows by Equation (21.35). The second inequality follows by

$$\|SV_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - SA\|_1 \leq \beta \min_{X_1,X_2,X_3} \|SV_1X_1 \otimes V_2X_2 \otimes V_3X_3 - SA\|_1.$$

The third inequality follows by Equation (21.36). The final inequality follows using that $\beta \geq 1$. □

Lemma 21.7.5. *Let* $\min(b_1, b_2, b_3) \geq k$. *Given three matrices* $V_1 \in \mathbb{R}^{n\times b_1}$, $V_2 \in \mathbb{R}^{n\times b_2}$, *and* $V_3 \in \mathbb{R}^{n\times b_3}$, *there exists an algorithm that takes* $O(\mathrm{nnz}(A)) + n\,\mathrm{poly}(b_1, b_2, b_3)$ *time and outputs a tensor* $C \in \mathbb{R}^{c_1\times c_2\times c_3}$ *and three matrices* $\widehat{V}_1 \in \mathbb{R}^{c_1\times b_1}$, $\widehat{V}_2 \in \mathbb{R}^{c_2\times b_2}$ *and* $\widehat{V}_3 \in \mathbb{R}^{c_3\times b_3}$

Algorithm 21.21 Reducing the Size of the Objective Function to poly(k)

procedure L1PolyKSizeReduction($A, V_1, V_2, V_3, n, b_1, b_2, b_3, k$) ▷ Lemma 21.7.5

with $c_1 = c_2 = c_3 = \mathrm{poly}(b_1, b_2, b_3)$*, such that with probability* 0.99*, for any* $\alpha \geq 1$*, if* X_1', X_2', X_3' *satisfy that,*

$$\left\| \sum_{i=1}^{k} (\widehat{V}_1 X_1')_i \otimes (\widehat{V}_2 X_2')_i \otimes (\widehat{V}_3 X_3')_i - C \right\|_1 \leq \alpha \min_{X_1, X_2, X_3} \left\| \sum_{i=1}^{k} (\widehat{V}_1 X_1)_i \otimes (\widehat{V}_2 X_2)_i \otimes (\widehat{V}_3 X_3)_i - C \right\|_1,$$

then,

$$\left\| \sum_{i=1}^{k} (V_1 X_1')_i \otimes (V_2 X_2')_i \otimes (V_3 X_3')_i - A \right\|_1 \lesssim \alpha \min_{X_1, X_2, X_3} \left\| \sum_{i=1}^{k} (V_1 X_1)_i \otimes (V_2 X_2)_i \otimes (V_3 X_3)_i - A \right\|_1.$$

Proof. For simplicity, we define OPT to be

$$\min_{X_1, X_2, X_3} \left\| \sum_{i=1}^{k} (V_1 X_1)_i \otimes (V_2 X_2)_i \otimes (V_3 X_3)_i - A \right\|_1.$$

Let $T_1 \in \mathbb{R}^{c_1 \times n}$ sample according to the Lewis weights of $V_1 \in \mathbb{R}^{n \times b_1}$, where $c_1 = \widetilde{O}(b_1)$. Let $T_2 \in \mathbb{R}^{c_2 \times n}$ sample according to the Lewis weights of $V_2 \in \mathbb{R}^{n \times b_2}$, where $c_2 = \widetilde{O}(b_2)$. Let $T_3 \in \mathbb{R}^{c_3 \times n}$ sample according to the Lewis weights of $V_3 \in \mathbb{R}^{n \times b_3}$, where $c_3 = \widetilde{O}(b_3)$.

For any $\alpha \geq 1$, let $X_1' \in \mathbb{R}^{b_1 \times k}, X_2' \in \mathbb{R}^{b_2 \times k}, X_3' \in \mathbb{R}^{b_3 \times k}$ satisfy

$$\begin{aligned}&\|T_1 V_1 X_1' \otimes T_2 V_2 X_2' \otimes T_3 V_3 X_3' - A(T_1, T_2, T_3)\|_1 \\ \leq\ & \alpha \min_{X_1 \in \mathbb{R}^{b_1 \times k}, X_2 \in \mathbb{R}^{b_2 \times k}, X_3 \in \mathbb{R}^{b_3 \times k}} \|T_1 V_1 X_1 \otimes T_2 V_2 X_2 \otimes T_3 V_3 X_3 - A(T_1, T_2, T_3)\|_1.\end{aligned}$$

First, we regard T_1 as the sketching matrix for the remainder. Then by Lemma D.11 in [SWZ17] and Theorem 21.7.4, we have

$$\begin{aligned}&\|V_1 X_1' \otimes T_2 V_2 X_2' \otimes T_3 V_3 X_3' - A(I, T_2, T_3)\|_1 \\ \lesssim\ & \alpha \min_{X_1 \in \mathbb{R}^{b_1 \times k}, X_2 \in \mathbb{R}^{b_2 \times k}, X_3 \in \mathbb{R}^{b_3 \times k}} \|V_1 X_1 \otimes T_2 V_2 X_2 \otimes T_3 V_3 X_3 - A(I, T_2, T_3)\|_1.\end{aligned}$$

Second, we regard T_2 as a sketching matrix for $V_1 X_1 \otimes V_2 X_2 \otimes T_3 V_3 X_3 - A(I, I, T_3)$. Then by Lemma D.11 in [SWZ17] and Theorem 21.7.4, we have

$$\begin{aligned}&\|V_1 X_1' \otimes V_2 X_2' \otimes T_3 V_3 X_3' - A(I, I, T_3)\|_1 \\ \lesssim\ & \alpha \min_{X_1 \in \mathbb{R}^{b_1 \times k}, X_2 \in \mathbb{R}^{b_2 \times k}, X_3 \in \mathbb{R}^{b_3 \times k}} \|V_1 X_1 \otimes V_2 X_2 \otimes T_3 V_3 X_3 - A(I, I, T_3)\|_1.\end{aligned}$$

Third, we regard T_3 as a sketching matrix for $V_1 X_1 \otimes V_2 X_2 \otimes V_3 X_3 - A$. Then by Lemma D.11 in [SWZ17] and Theorem 21.7.4, we have

$$\left\| \sum_{i=1}^k (V_1 X_1')_i \otimes (V_2 X_2')_i \otimes (V_3 X_3')_i - A \right\|_1 \lesssim \alpha \min_{X_1, X_2, X_3} \left\| \sum_{i=1}^k (V_1 X_1)_i \otimes (V_2 X_2)_i \otimes (V_3 X_3)_i - A \right\|_1.$$

□

Lemma 21.7.6. *Given tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, and two matrices $U \in \mathbb{R}^{n_1 \times s}, V \in \mathbb{R}^{n_2 \times s}$ with $\mathrm{rank}(U) = r$, let $T \in \mathbb{R}^{t \times n_1}$ be a sampling/rescaling matrix according to the Lewis weights of U with $t = \widetilde{O}(r)$. Then with probability at least 0.99, for all $X' \in \mathbb{R}^{n_3 \times s}, \alpha \geq 1$ which satisfy*

$$\|T_1 U \otimes V \otimes X' - T_1 A\|_1 \leq \alpha \cdot \min_{X \in \mathbb{R}^{n_3 \times s}} \|T_1 U \otimes V \otimes X - T_1 A\|_1,$$

it holds that

$$\|U \otimes V \otimes X' - A\|_1 \lesssim \alpha \cdot \min_{X \in \mathbb{R}^{n_3 \times s}} \|U \otimes V \otimes X - A\|_1.$$

The proof is similar to the proof of Lemma 21.7.5.

Proof. Let $X^* = \arg\min_{X \in \mathbb{R}^{n_3 \times s}} \|U \otimes V \otimes X - A\|_1$. Then according to Lemma D.11 in [SWZ17], T has at most constant dilation (Definition 21.7.2) on $U \cdot (V^\top \odot (X^*)^\top) - A_1$, and has at most constant contraction (Definition 21.7.3) on U. We first look at

$$\begin{aligned}
& \|TU \otimes V \otimes X' - TA\|_1 \\
= & \|TU \cdot (V^\top \odot (X')^\top) - TA_1\|_1 \\
\geq & \|TU \cdot ((V^\top \odot (X')^\top) - (V^\top \odot (X^*)^\top))\|_1 - \|TU \cdot (V^\top \odot (X^*)^\top) - TA_1\|_1 \\
\geq & \frac{1}{\beta_2} \|U \cdot ((V^\top \odot (X')^\top) - A_1\|_1 - (\frac{1}{\beta_2} + \beta_1) \|U \cdot (V^\top \odot (X^*)^\top) - A_1\|_1,
\end{aligned}$$

where $\beta_1 \geq 1, \beta_2 \geq 1$ are two constants. Then we have:

$$\begin{aligned}
& \|U \otimes V \otimes X' - A\|_1 \\
\leq & \beta_2 \|TU \cdot (V^\top \odot (X')^\top) - TA_1\|_1 + (1 + \beta_1 \beta_2) \|U \cdot (V^\top \odot (X^*)^\top) - A_1\|_1 \\
\leq & \alpha \beta_2 \|TU \cdot (V^\top \odot (X^*)^\top) - TA_1\|_1 + (1 + \beta_1 \beta_2) \|U \cdot (V^\top \odot (X^*)^\top) - A_1\|_1 \\
\leq & \alpha \beta_1 \beta_2 \|U \cdot (V^\top \odot (X^*)^\top) - A_1\|_1 + (1 + \beta_1 \beta_2) \|U \cdot (V^\top \odot (X^*)^\top) - A_1\|_1 \\
\lesssim & \alpha \|U \otimes V \otimes X^* - A\|_1.
\end{aligned}$$

□

Corollary 21.7.7. *Given tensor $A \in \mathbb{R}^{n \times n \times n}$, and two matrices $U \in \mathbb{R}^{n \times s}, V \in \mathbb{R}^{n \times s}$ with $\mathrm{rank}(U) = r_1, \mathrm{rank}(V) = r_2$, let $T_1 \in \mathbb{R}^{t_1 \times n}$ be a sampling/rescaling matrix according to*

the Lewis weights of U, and let $T_2 \in \mathbb{R}^{t_2 \times n}$ be a sampling/rescaling matrix according to the Lewis weights of V with $t_1 = \widetilde{O}(r_1), t_2 = \widetilde{O}(r_2)$. Then with probability at least 0.99, for all $X' \in \mathbb{R}^{n \times s}, \alpha \geq 1$ which satisfy

$$\|T_1 U \otimes T_2 V \otimes X' - A(T_1, T_2, I)\|_1 \leq \alpha \cdot \min_{X \in \mathbb{R}^{n \times s}} \|T_1 U \otimes T_2 V \otimes X - A(T_1, T_2, I)\|_1,$$

it holds that

$$\|U \otimes V \otimes X' - A\|_1 \lesssim \alpha \cdot \min_{X \in \mathbb{R}^{n \times s}} \|U \otimes V \otimes X - A\|_1.$$

Proof. We apply Lemma 21.7.6 twice: if

$$\|T_1 U \otimes T_2 V \otimes X' - A(T_1, T_2, I)\|_1 \leq \alpha \cdot \min_{X \in \mathbb{R}^{n \times s}} \|T_1 U \otimes T_2 V \otimes X - A(T_1, T_2, I)\|_1,$$

then

$$\|U \otimes T_2 V \otimes X' - A(I, T_2, I)\|_1 \lesssim \alpha \cdot \min_{X \in \mathbb{R}^{n \times s}} \|U \otimes T_2 V \otimes X - A(I, T_2, I)\|_1.$$

Then, we have

$$\|U \otimes V \otimes X' - A\|_1 \lesssim \alpha \cdot \min_{X \in \mathbb{R}^{n \times s}} \|U \otimes V \otimes X - A\|_1.$$

□

21.7.4 Solving small problems

Theorem 21.7.8. *Let* $\max_i\{t_i, d_i\} \leq n$. *Given a* $t_1 \times t_2 \times t_3$ *tensor* A *and three matrices: a* $t_1 \times d_1$ *matrix* T_1, *a* $t_2 \times d_2$ *matrix* T_2, *and a* $t_3 \times d_3$ *matrix* T_3, *if for* $\delta > 0$ *there exists a solution to*

$$\min_{X_1,X_2,X_3} \left\| \sum_{i=1}^{k} (T_1X_1)_i \otimes (T_2X_2)_i \otimes (T_3X_3)_i - A \right\|_1 := \mathrm{OPT},$$

such that each entry of X_i *can be expressed using* $O(n^\delta)$ *bits, then there exists an algorithm that takes* $n^{O(\delta)} \cdot 2^{O(d_1k+d_2k+d_3k)}$ *time and outputs three matrices:* $\widehat{X}_1$, $\widehat{X}_2$, *and* $\widehat{X}_3$ *such that* $\|(T_1\widehat{X}_1) \otimes (T_2\widehat{X}_2) \otimes (T_3\widehat{X}_3) - A\|_1 = \mathrm{OPT}$.

Proof. For each $i \in [3]$, we can create $t_i \times d_i$ variables to represent matrix X_i. Let x denote the list of these variables. Let B denote tensor $\sum_{i=1}^{k} (T_1X_1)_i \otimes (T_2X_2)_i \otimes (T_3X_3)_i$. Then we can write the following objective function,

$$\min_x \sum_{i=1}^{t_1} \sum_{j=1}^{t_2} \sum_{l=1}^{t_3} |B_{i,j,l}(x) - A_{i,j,l}|.$$

To remove the $|\cdot|$, we create $t_1t_2t_3$ extra variables $\sigma_{i,j,l}$. Then we obtain the objective function:

$$\begin{aligned} \min_{x,\sigma} \ & \sum_{i=1}^{t_1} \sum_{j=1}^{t_2} \sum_{l=1}^{t_3} \sigma_{i,j,l}(B_{i,j,l}(x) - A_{i,j,l}) \\ \text{s.t. } & \sigma_{i,j,l}^2 = 1, \\ & \sigma_{i,j,l}(B_{i,j,l}(x) - A_{i,j,l}) \geq 0, \\ & \|x\|_2^2 + \|\sigma\|_2^2 \leq 2^{O(n^\delta)} \end{aligned}$$

where the last constraint is unharmful, because there exists a solution that can be written using $O(n^\delta)$ bits. Note that the number of inequality constraints in the above system is

$O(t_1t_2t_3)$, the degree is $O(1)$, and the number of variables is $v = (t_1t_2t_3 + d_1k + d_2k + d_3k)$. Thus by Theorem 21.3.2, we know that the minimum nonzero cost is at least

$$(2^{O(n^\delta)})^{-2^{\widetilde{O}(v)}}.$$

It is immediate that the upper bound on cost is at most $2^{O(n^\delta)}$, and thus the number of binary search steps is at most $\log(2^{O(n^\delta)})2^{\widetilde{O}(v)}$. In each step of the binary search, we need to choose a cost C between the lower bound and the upper bound, and write down the polynomial system,

$$\begin{aligned}
&\sum_{i=1}^{t_1}\sum_{j=1}^{t_2}\sum_{l=1}^{t_3}\sigma_{i,j,l}(B_{i,j,l}(x) - A_{i,j,l}) \leq C,\\
&\sigma_{i,j,l}^2 = 1,\\
&\sigma_{i,j,l}(B_{i,j,l}(x) - A_{i,j,l}) \geq 0,\\
&\|x\|_2^2 + \|\sigma\|_2^2 \leq 2^{O(n^\delta)}.
\end{aligned}$$

Using Theorem 21.3.1, we can determine if there exists a solution to the above polynomial system. Since the number of variables is v, and the degree is $O(1)$, the number of inequality constraints is $t_1t_2t_2$. Thus, the running time is

$$\text{poly}(\text{bitsize}) \cdot (\#\,\text{constraints} \cdot \text{degree})^{\#\,\text{variables}} = n^{O(\delta)}2^{\widetilde{O}(v)}$$

□

21.7.5 Bicriteria algorithms

We present several bicriteria algorithms with different tradeoffs. We first present an algorithm that runs in nearly linear time and outputs a solution with rank $\widetilde{O}(k^3)$ in Theorem 21.7.9. Then we show an algorithm that runs in $\mathrm{nnz}(A)$ time but outputs a solution with rank $\mathrm{poly}(k)$ in Theorem 21.7.10. Then we explain an idea which is able to decrease the cubic rank to quadratic rank, and thus we can obtain Theorem 21.7.11 and Theorem 21.7.12.

21.7.5.1 Input sparsity time

Algorithm 21.22 ℓ_1-Low Rank Approximation, Bicriteria Algorithm, rank-$\widetilde{O}(k^3)$, Nearly Input Sparsity Time

procedure L1BicriteriaAlgorithm(A, n, k) ▷ Theorem 21.7.9
  $s_1 \leftarrow s_2 \leftarrow s_3 \leftarrow \widetilde{O}(k)$.
  For each $i \in [3]$, choose $S_i \in \mathbb{R}^{n^2 \times s_i}$ to be a dense Cauchy transform. ▷ Part (I) of Theorem 21.7.2
  Compute $A_1 \cdot S_1$, $A_2 \cdot S_2$, $A_3 \cdot S_3$.
  $Y_1, Y_2, Y_3, C \leftarrow$L1PolyKSizeReduction($A, A_1S_1, A_2S_2, A_3S_3, n, s_1, s_2, s_3, k$) ▷ Algorithm 21.21
  Form objective function

$$\min_{X \in \mathbb{R}^{s_1 \times s_2 \times s_3}} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} X_{i,j,l} (Y_1)_i \otimes (Y_2)_j \otimes (Y_3)_l - C \right\|_1 .$$

  Run ℓ_1-regression solver to find X.
  return A_1S_1, A_2S_2, A_3S_3 and X.
end procedure

Theorem 21.7.9. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$, $\epsilon \in (0,1)$, let $r = \widetilde{O}(k^3)$. There exists an algorithm which takes $\mathrm{nnz}(A) \cdot \widetilde{O}(k) + O(n)\,\mathrm{poly}(k) + \mathrm{poly}(k)$*

time and outputs three matrices $U, V, W \in \mathbb{R}^{n\times r}$ *such that*

$$\left\|\sum_{i=1}^{r} U_i \otimes V_i \otimes W_i - A\right\|_1 \leq \widetilde{O}(k^{3/2}) \log^3 n \min_{\mathrm{rank}-k\ A_k} \|A_k - A\|_1$$

holds with probability 9/10.

Proof. We first choose three dense Cauchy transforms $S_i \in \mathbb{R}^{n^2\times s_i}$. According to Section 21.3.7, for each $i \in [3]$, $A_i S_i$ can be computed in $\mathrm{nnz}(A) \cdot \widetilde{O}(k)$ time. Then we apply Lemma 21.7.5 (Algorithm 21.21). We obtain three matrices Y_1, Y_2, Y_3 and a tensor C. Note that for each $i \in [3]$, Y_i can be computed in $n\,\mathrm{poly}(k)$ time. Because $C = A(T_1, T_2, T_3)$ and $T_1, T_2, T_3 \in \mathbb{R}^{n\times\widetilde{O}(k)}$ are three sampling and rescaling matrices, C can be computed in $\mathrm{nnz}(A) + \widetilde{O}(k^3)$ time. At the end, we just need to run an ℓ_1-regression solver to find the solution to the problem,

$$\min_{X\in\mathbb{R}^{s_1\times s_2\times s_3}} \left\|\sum_{i=1}^{s_1}\sum_{j=1}^{s_2}\sum_{l=1}^{s_3} X_{i,j,l}(Y_1)_i \otimes (Y_2)_j \otimes (Y_3)_j\right\|_1,$$

where $(Y_1)_i$ denotes the i-th column of matrix Y_1. Since the size of the above problem is only $\mathrm{poly}(k)$, this can be solved in $\mathrm{poly}(k)$ time. □

Theorem 21.7.10. *Given a* 3*rd order tensor* $A \in \mathbb{R}^{n\times n\times n}$*, for any* $k \geq 1$*,* $\epsilon \in (0, 1)$*, let* $r = \widetilde{O}(k^{15})$*. There exists an algorithm that takes* $\mathrm{nnz}(A) + O(n)\,\mathrm{poly}(k) + \mathrm{poly}(k)$ *time and outputs three matrices* $U, V, W \in \mathbb{R}^{n\times r}$ *such that*

$$\left\|\sum_{i=1}^{r} U_i \otimes V_i \otimes W_i - A\right\|_1 \leq \mathrm{poly}(k, \log n) \min_{\mathrm{rank}-k\ A_k} \|A_k - A\|_1$$

holds with probability 9/10.

Algorithm 21.23 ℓ_1-Low Rank Approximation, Bicriteria Algorithm, rank-poly(k), Input Sparsity Time

procedure L1BicriteriaAlgorithm(A, n, k) ▷ Theorem 21.7.10
  $s_1 \leftarrow s_2 \leftarrow s_3 \leftarrow \widetilde{O}(k^5)$.
  For each $i \in [3]$, choose $S_i \in \mathbb{R}^{n^2 \times s_i}$ to be a sparse Cauchy transform. ▷ Part (II) of Theorem 21.7.3
  Compute $A_1 \cdot S_1$, $A_2 \cdot S_2$, $A_3 \cdot S_3$.
  $Y_1, Y_2, Y_3, C \leftarrow$L1PolyKSizeReduction$(A, A_1S_1, A_2S_2, A_3, S_3, n, s_1, s_2, s_3, k)$ ▷ Algorithm 21.21
  Form objective function

$$\min_{X \in \mathbb{R}^{s_1 \times s_2 \times s_3}} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} X_{i,j,l} (Y_1)_i \otimes (Y_2)_j \otimes (Y_3)_l - C \right\|_1 .$$

  Run ℓ_1-regression solver to find X.
  return A_1S_1, A_2S_2, A_3S_3 and X.
end procedure

Proof. We first choose three dense Cauchy transforms $S_i \in \mathbb{R}^{n^2 \times s_i}$. According to Section 21.3.7, for each $i \in [3]$, A_iS_i can be computed in $O(\mathrm{nnz}(A))$ time. Then we apply Lemma 21.7.5 (Algorithm 21.21), and can obtain three matrices Y_1, Y_2, Y_3 and a tensor C. Note that for each $i \in [3]$, Y_i can be computed in $O(n)\,\mathrm{poly}(k)$ time. Because $C = A(T_1, T_2, T_3)$ and $T_1, T_2, T_3 \in \mathbb{R}^{n \times \widetilde{O}(k)}$ are three sampling and rescaling matrices, C can be computed in $\mathrm{nnz}(A) + \widetilde{O}(k^3)$ time. At the end, we just need to run an ℓ_1-regression solver to find the solution to the problem,

$$\min_{X \in \mathbb{R}^{s_1 \times s_2 \times s_3}} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} X_{i,j,l} (Y_1)_i \otimes (Y_2)_j \otimes (Y_3)_l - C \right\|_1 ,$$

where $(Y_1)_i$ denotes the i-th column of matrix Y_1. Since the size of the above problem is only $\mathrm{poly}(k)$, it can be solved in $\mathrm{poly}(k)$ time. □

21.7.5.2 Improving cubic rank to quadratic rank

Algorithm 21.24 ℓ_1-Low Rank Approximation, Bicriteria Algorithm, rank-$\widetilde{O}(k^2)$, Nearly Input Sparsity Time

procedure L1BicriteriaAlgorithm(A, n, k) ▷ Theorem 21.7.11
  $s_1 \leftarrow s_2 \leftarrow s_3 \leftarrow \widetilde{O}(k)$.
  For each $i \in [3]$, choose $S_i \in \mathbb{R}^{n^2 \times s_i}$ to be a dense Cauchy transform. ▷ Part (I) of Theorem 21.7.2
  Compute $A_1 \cdot S_1$, $A_2 \cdot S_2$.
  For each $i \in [2]$, choose T_i to be a sampling and rescaling diagonal matrix according to the Lewis weights of $A_i S_i$, with $t_i = \widetilde{O}(k)$ nonzero entries.
  $C \leftarrow A(T_1, T_2, I)$.
  $B^{i+(j-1)s_1} \leftarrow \mathrm{vec}((T_1 A_1 S_1)_i \otimes (T_2 A_2 S_2)_j), \forall i \in [s_1], j \in [s_2]$.
  Form objective function $\min_W \|WB - C_3\|_1$
  Run ℓ_1-regression solver to find $\widehat{W}$.
  Construct $\widehat{U}$ by using $A_1 S_1$ according to Equation (21.38).
  Construct $\widehat{V}$ by using $A_2 S_2$ according to Equation (21.39).
  return $\widehat{U}, \widehat{V}, \widehat{W}$.
end procedure

Theorem 21.7.11. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$, $\epsilon \in (0,1)$, let $r = \widetilde{O}(k^2)$. There exists an algorithm which takes $\mathrm{nnz}(A) \cdot \widetilde{O}(k) + O(n)\,\mathrm{poly}(k) + \mathrm{poly}(k)$ time and outputs three matrices $U, V, W \in \mathbb{R}^{n \times r}$ such that*

$$\left\| \sum_{i=1}^{r} U_i \otimes V_i \otimes W_i - A \right\|_1 \leq \widetilde{O}(k^{3/2}) \log^3 n \min_{\mathrm{rank}-k\ A_k} \|A_k - A\|_1$$

holds with probability 9/10.

Proof. Let $\mathrm{OPT} = \min_{A_k \in \mathbb{R}^{n \times n \times n}} \|A_k - A\|_1$. We first choose three dense Cauchy transforms $S_i \in \mathbb{R}^{n^2 \times s_i}$, $\forall i \in [3]$. According to Section 21.3.7, for each $i \in [3]$, $A_i S_i$ can be computed in $\mathrm{nnz}(A) \cdot \widetilde{O}(k)$ time. Then we choose T_i to be a sampling and rescaling diagonal matrix according to the Lewis weights of $A_i S_i$, $\forall i \in [2]$.

According to Theorem 21.7.3, we have

$$\min_{X_1\in\mathbb{R}^{s_1\times k},X_2\in\mathbb{R}^{s_2\times k},X_3\in\mathbb{R}^{s_3\times k}}\left\|\sum_{l=1}^{k}(A_1S_1X_1)_l\otimes(A_2S_2X_2)_l\otimes(A_3S_3X_3)_l-A\right\|_1\leq\widetilde{O}(k^{1.5})\log^3 n\,\mathrm{OPT}$$

Now we fix an l and we have:

$$\begin{aligned}&(A_1S_1X_1)_l\otimes(A_2S_2X_2)_l\otimes(A_3S_3X_3)_l\\=&\left(\sum_{i=1}^{s_1}(A_1S_1)_i(X_1)_{i,l}\right)\otimes\left(\sum_{j=1}^{s_2}(A_2S_2)_j(X_2)_{j,l}\right)\otimes(A_3S_3X_3)_l\\=&\sum_{i=1}^{s_1}\sum_{j=1}^{s_2}(A_1S_1)_i\otimes(A_2S_2)_j\otimes(A_3S_3X_3)_l(X_1)_{i,l}(X_2)_{j,l}\end{aligned}$$

Thus, we have

$$\min_{X_1,X_2,X_3}\left\|\sum_{i=1}^{s_1}\sum_{j=1}^{s_2}(A_1S_1)_i\otimes(A_2S_2)_j\otimes\left(\sum_{l=1}^{k}(A_3S_3X_3)_l(X_1)_{i,l}(X_2)_{j,l}\right)-A\right\|_1\leq\widetilde{O}(k^{1.5})\log^3 n\,\mathrm{OPT}\,. \tag{21.37}$$

We create matrix $\widehat{U}\in\mathbb{R}^{n\times s_1s_2}$ by copying matrix A_1S_1 s_2 times, i.e.,

$$\widehat{U}=\begin{bmatrix}A_1S_1 & A_1S_1 & \cdots & A_1S_1\end{bmatrix}. \tag{21.38}$$

We create matrix $\widehat{V}\in\mathbb{R}^{n\times s_1s_2}$ by copying the i-th column of A_2S_2 a total of s_1 times into the columns $(i-1)s_1,\cdots,is_1$ of $\widehat{V}$, for each $i\in[s_2]$, i.e.,

$$\widehat{V}=\begin{bmatrix}(A_2S_2)_1 & \cdots & (A_2S_2)_1 & (A_2S_2)_2 & \cdots & (A_2S_2)_2 & \cdots(A_2S_2)_{s_2} & \cdots & (A_2S_2)_{s_2}.\end{bmatrix} \tag{21.39}$$

According to Equation (21.37), we have:

$$\min_{W\in\mathbb{R}^{n\times s_1s_2}}\|\widehat{U}\otimes\widehat{V}\otimes W-A\|_1\leq\widetilde{O}(k^{1.5})\log^3 n\cdot\mathrm{OPT}\,.$$

Let

$$\widehat{W} = \arg\min_{W \in \mathbb{R}^{n \times s_1 s_2}} \|T_1 \widehat{U} \otimes T_2 \widehat{V} \otimes W - A(T_1, T_2, I)\|_1.$$

Due to Corollary 21.7.7, we have

$$\|\widehat{U} \otimes \widehat{V} \otimes \widehat{W} - A\|_1 \leq \widetilde{O}(k^{1.5}) \log^3 n \cdot \mathrm{OPT}\,.$$

Putting it all together, we have that $\widehat{U}, \widehat{V}, \widehat{W}$ gives a rank-$\widetilde{O}(k^2)$ bicriteria algorithm to the original problem. □

Algorithm 21.25 ℓ_1-Low Rank Approximation, Bicriteria Algorithm, rank-poly(k), Input Sparsity Time

procedure L1BicriteriaAlgorithm(A, n, k) ▷ Theorem 21.7.12
  $s_1 \leftarrow s_2 \leftarrow s_3 \leftarrow \widetilde{O}(k^5)$.
  For each $i \in [3]$, choose $S_i \in \mathbb{R}^{n^2 \times s_i}$ to be a sparse Cauchy transform. ▷ Part (II) of Theorem 21.7.2
  Compute $A_1 \cdot S_1$, $A_2 \cdot S_2$.
  For each $i \in [2]$, choose T_i to be a sampling and rescaling diagonal matrix according to the Lewis weights of $A_i S_i$, with $t_i = \widetilde{O}(k)$ nonzero entries.
  $C \leftarrow A(T_1, T_2, I)$.
  $B^{i+(j-1)s_1} \leftarrow \mathrm{vec}((T_1 A_1 S_1)_i \otimes (T_2 A_2 S_2)_j), \forall i \in [s_1], j \in [s_2]$.
  Form objective function $\min_W \|WB - C_3\|_1$.
  Run ℓ_1-regression solver to find $\widehat{W}$.
  Construct $\widehat{U}$ by using $A_1 S_1$ according to Equation (21.38).
  Construct $\widehat{V}$ by using $A_2 S_2$ according to Equation (21.39).
  return $\widehat{U}, \widehat{V}, \widehat{W}$.
end procedure

Theorem 21.7.12. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$, $\epsilon \in (0,1)$, let $r = \widetilde{O}(k^{10})$. There exists an algorithm which takes $\mathrm{nnz}(A) + O(n)\,\mathrm{poly}(k) + \mathrm{poly}(k)$ time*

and outputs three matrices $U, V, W \in \mathbb{R}^{n \times r}$ such that

$$\left\| \sum_{i=1}^{r} U_i \otimes V_i \otimes W_i - A \right\|_1 \leq \mathrm{poly}(k, \log n) \min_{\mathrm{rank}-k \ A_k} \|A_k - A\|_1$$

holds with probability $9/10$.

Proof. The proof is similar to the proof of Theorem 21.7.11. The only difference is that instead of choosing dense Cauchy matrices S_1, S_2, we choose sparse Cauchy matrices. □

Notice that if we firstly apply a sparse Cauchy transform, we can reduce the rank of the matrix to $\mathrm{poly}(k)$. Then we apply a dense Cauchy transform and can further reduce the dimension while only incurring another $\mathrm{poly}(k)$ factor in the approximation ratio. By combining a sparse Cauchy transform and a dense Cauchy transform, we can improve the running time from $\mathrm{nnz}(A) \cdot \widetilde{O}(k)$ to $\mathrm{nnz}(A)$.

Corollary 21.7.13. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$, $\epsilon \in (0, 1)$, let $r = \widetilde{O}(k^2)$. There exists an algorithm which takes $\mathrm{nnz}(A) + O(n)\,\mathrm{poly}(k) + \mathrm{poly}(k)$ time and outputs three matrices $U, V, W \in \mathbb{R}^{n \times r}$ such that*

$$\left\| \sum_{i=1}^{r} U_i \otimes V_i \otimes W_i - A \right\|_1 \leq \mathrm{poly}(k, \log n) \min_{\mathrm{rank}-k \ A_k} \|A_k - A\|_1$$

holds with probability $9/10$.

Algorithm 21.26 ℓ_1-Low Rank Approximation, Bicriteria Algorithm, rank-$\widetilde{O}(k^2)$, Input Sparsity Time

procedure L1BICRITERIAALGORITHM(A, n, k) ▷ Corollary 21.7.13
  $s_1 \leftarrow s_2 \leftarrow s_3 \leftarrow \widetilde{O}(k)$.
  For each $i \in [3]$, choose $S_i \in \mathbb{R}^{n^2 \times s_i}$ to be the composition of a sparse Cauchy transform and a dense Cauchy transform. ▷ Part (I,II) of Theorem 21.7.2
  Compute $A_1 \cdot S_1$, $A_2 \cdot S_2$.
  For each $i \in [2]$, choose T_i to be a sampling and rescaling diagonal matrix according to the Lewis weights of $A_i S_i$, with $t_i = \widetilde{O}(k)$ nonzero entries.
  $C \leftarrow A(T_1, T_2, I)$.
  $B^{i+(j-1)s_1} \leftarrow \mathrm{vec}((T_1 A_1 S_1)_i \otimes (T_2 A_2 S_2)_j), \forall i \in [s_1], j \in [s_2]$.
  Form objective function $\min_W \|WB - C_3\|_1$.
  Run ℓ_1-regression solver to find $\widehat{W}$.
  Construct $\widehat{U}$ by using $A_1 S_1$ according to Equation (21.38).
  Construct $\widehat{V}$ by using $A_2 S_2$ according to Equation (21.39).
  return $\widehat{U}, \widehat{V}, \widehat{W}$.
end procedure

21.7.6 Algorithms

In this section, we show two different algorithms by using different kind of sketches. One is shown in Theorem 21.7.14 which gives a fast running time. Another one is shown in Theorem 21.7.16 which gives the best approximation ratio.

21.7.6.1 Input sparsity time algorithm

Theorem 21.7.14. *Given a 3rd tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$, there exists an algorithm that takes $\mathrm{nnz}(A) \cdot \widetilde{O}(k) + O(n)\,\mathrm{poly}(k) + 2^{\widetilde{O}(k^2)}$ time and outputs three matrices $U, V, W \in \mathbb{R}^{n \times k}$ such that,*

$$\|U \otimes V \otimes W - A\|_1 \leq \mathrm{poly}(k, \log n) \min_{\mathrm{rank}-k\ A'} \|A' - A\|_1.$$

Algorithm 21.27 ℓ_1-Low Rank Approximation, Input sparsity Time Algorithm

procedure L1TensorLowRankApproxInputSparsity(A, n, k) ▷ Theorem 21.7.14
  $s_1 \leftarrow s_2 \leftarrow s_3 \leftarrow \widetilde{O}(k^5)$.
  Choose $S_i \in \mathbb{R}^{n^2 \times s_i}$ to be a dense Cauchy transform, $\forall i \in [3]$. ▷ Part (I) of Theorem 21.7.3
  Compute $A_1 \cdot S_1$, $A_2 \cdot S_2$, and $A_3 \cdot S_3$.
  $Y_1, Y_2, Y_3, C \leftarrow$L1PolyKSizeReduction$(A, A_1S_1, A_2S_2, A_3S_3, n, s_1, s_2, s_3, k)$. ▷ Algorithm 21.21
  Create variables $s_1 \times k + s_2 \times k + s_3 \times k$ variables for each entry of X_1, X_2, X_3.
  Form objective function $\|(Y_1X_1) \otimes (Y_2X_2) \otimes (Y_3X_3) - C\|_F^2$.
  Run polynomial system verifier.
  return $A_1S_1X_1, A_2S_2X_2, A_3S_3X_3$.
end procedure

holds with probability at least $9/10$.

Proof. First, we apply part (II) of Theorem 21.7.3. Then A_iS_i can be computed in $O(\mathrm{nnz}(A))$ time. Second, we use Lemma 21.7.5 to reduce the size of the objective function from $O(n^3)$ to $\mathrm{poly}(k)$ in $n\,\mathrm{poly}(k)$ time by only losing a constant factor in approximation ratio. Third, we use Claim 21.3.6 to relax the objective function from entry-wise ℓ_1-norm to Frobenius norm, and this step causes us to lose some other $\mathrm{poly}(k)$ factors in approximation ratio. As a last step, we use Theorem 21.4.44 to solve the Frobenius norm objective function. □

Notice again that if we first apply a sparse Cauchy transform, we can reduce the rank of the matrix to $\mathrm{poly}(k)$. Then as before we can apply a dense Cauchy transform to further reduce the dimension while only incurring another $\mathrm{poly}(k)$ factor in the approximation ratio. By combining a sparse Cauchy transform and a dense Cauchy transform, we can improve the running time from $\mathrm{nnz}(A) \cdot \widetilde{O}(k)$ to $\mathrm{nnz}(A)$, while losing some additional $\mathrm{poly}(k)$ factors in approximation ratio.

Corollary 21.7.15. *Given a 3rd tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$, there exists an algorithm that takes $\mathrm{nnz}(A) + O(n)\,\mathrm{poly}(k) + 2^{\widetilde{O}(k^2)}$ time and outputs three matrices $U, V, W \in \mathbb{R}^{n \times k}$ such that,*

$$\|U \otimes V \otimes W - A\|_1 \leq \mathrm{poly}(k, \log n) \min_{\mathrm{rank}-k\ A'} \|A' - A\|_1.$$

holds with probability at least 9/10.

21.7.6.2 $\widetilde{O}(k^{3/2})$-approximation algorithm

Algorithm 21.28 ℓ_1-Low Rank Approximation Algorithm, $\widetilde{O}(k^{3/2})$-approximation

procedure L1TensorLowRankApproxK(A, n, k) ▷ Theorem 21.7.16
  $s_1 \leftarrow s_2 \leftarrow s_3 \leftarrow \widetilde{O}(k)$.
  Guess diagonal matrices $S_i \in \mathbb{R}^{n^2 \times s_i}$ with s_i nonzero entries, $\forall i \in [3]$. ▷ Part (III) of Theorem 21.7.3
  Compute $A_1 \cdot S_1$, $A_2 \cdot S_2$, and $A_3 \cdot S_3$.
  $Y_1, Y_2, Y_3, C \leftarrow$L1PolyKSizeReduction($A, A_1S_1, A_2S_2, A_3S_3, n, s_1, s_2, s_3, k$). ▷ Algorithm 21.21
  Create $s_1 \times k + s_2 \times k + s_3 \times k$ variables for each entry of X_1, X_2, X_3.
  Form objective function $\|(Y_1X_1) \otimes (Y_2X_2) \otimes (Y_3X_3) - C\|_1$.
  Run polynomial system verifier.
  return U, V, W.
end procedure

Theorem 21.7.16. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$, there exists an algorithm that takes $n^{\widetilde{O}(k)} 2^{\widetilde{O}(k^3)}$ time and output three matrices $U, V, W \in \mathbb{R}^{n \times k}$ such that,*

$$\|U \otimes V \otimes W - A\|_1 \leq \widetilde{O}(k^{3/2}) \min_{\mathrm{rank}-k\ A'} \|A' - A\|_1.$$

holds with probability at least 9/10.

Proof. First, we apply part (III) of Theorem 21.7.3. Then, guessing S_i requires $n^{\widetilde{O}(k)}$ time. Second, we use Lemma 21.7.5 to reduce the size of the objective from $O(n^3)$ to poly(k) in polynomial time while only losing a constant factor in approximation ratio. Third, we use Theorem 21.7.8 to solve the entry-wise ℓ_1-norm objective function directly. □

21.7.7 CURT decomposition

Algorithm 21.29 ℓ_1-CURT Decomposition Algorithm

procedure L1CURT(A, U_B, V_B, W_B, n, k) ▷ Theorem 21.7.17
  Form $B_1 = V_B^\top \odot W_B^\top \in \mathbb{R}^{k \times n^2}$.
  Let $D_1^\top \in \mathbb{R}^{n^2 \times n^2}$ be the sampling and rescaling diagonal matrix corresponding to the Lewis weights of $B_1^\top$, and let D_1 have $d_1 = O(k \log k)$ nonzero entries.
  Form $\widehat{U} = A_1 D_1 (B_1 D_1)^\dagger \in \mathbb{R}^{n \times k}$.
  Form $B_2 = \widehat{U}^\top \odot W_B^\top \in \mathbb{R}^{k \times n^2}$.
  Let $D_2^\top \in \mathbb{R}^{n^2 \times n^2}$ be the sampling and rescaling diagonal matrix corresponding to the Lewis weights of $B_2^\top$, and let D_2 have $d_2 = O(k \log k)$ nonzero entries.
  Form $\widehat{V} = A_2 D_2 (B_2 D_2)^\dagger \in \mathbb{R}^{n \times k}$.
  Form $B_3 = \widehat{U}^\top \odot \widehat{V}^\top \in \mathbb{R}^{k \times n^2}$.
  Let $D_3^\top \in \mathbb{R}^{n^2 \times n^2}$ be the sampling and rescaling diagonal matrix corresponding to the Lewis weights of $B_3^\top$, and let D_3 have $d_3 = O(k \log k)$ nonzero entries.
  $C \leftarrow A_1 D_1$, $R \leftarrow A_2 D_2$, $T \leftarrow A_3 D_3$.
  $U \leftarrow \sum_{i=1}^k ((B_1 D_1)^\dagger)_i \otimes ((B_2 D_2)^\dagger)_i \otimes ((B_3 D_3)^\dagger)_i$.
  return C, R, T and U.
end procedure

Theorem 21.7.17. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, let $k \geq 1$, let $U_B, V_B, W_B \in \mathbb{R}^{n \times k}$ denote a rank-k, α-approximation to A. Then there exists an algorithm which takes $O(\mathrm{nnz}(A)) + O(n^2)\,\mathrm{poly}(k)$ time and outputs three matrices: $C \in \mathbb{R}^{n \times c}$ with columns from A, $R \in \mathbb{R}^{n \times r}$ with rows from A, $T \in \mathbb{R}^{n \times t}$ with tubes from A, and a tensor $U \in \mathbb{R}^{c \times r \times t}$ with $\mathrm{rank}(U) = k$ such that $c = r = t = O(k \log k)$, and*

$$\left\| \sum_{i=1}^{c} \sum_{j=1}^{r} \sum_{l=1}^{t} U_{i,j,l} \cdot C_i \otimes R_j \otimes T_l - A \right\|_1 \leq \widetilde{O}(k^{1.5}) \alpha \min_{\mathrm{rank}-k\ A'} \|A' - A\|_1$$

holds with probability $9/10$.

Proof. We define

$$\mathrm{OPT} := \min_{\mathrm{rank}-k\ A'} \|A' - A\|_1.$$

We already have three matrices $U_B \in \mathbb{R}^{n\times k}$, $V_B \in \mathbb{R}^{n\times k}$ and $W_B \in \mathbb{R}^{n\times k}$ and these three matrices provide a rank-k, α approximation to A, i.e.,

$$\left\| \sum_{i=1}^{k} (U_B)_i \otimes (V_B)_i \otimes (W_B)_i - A \right\|_1 \leq \alpha\, \mathrm{OPT} \tag{21.40}$$

Let $B_1 = V_B^\top \odot W_B^\top \in \mathbb{R}^{k\times n^2}$ denote the matrix where the i-th row is the vectorization of $(V_B)_i \otimes (W_B)_i$. By Section B.3, we can compute $D_1 \in \mathbb{R}^{n^2\times n^2}$ which is a sampling and rescaling matrix corresponding to the Lewis weights of $B_1^\top$ in $O(n^2\,\mathrm{poly}(k))$ time, and there are $d_1 = O(k\log k)$ nonzero entries on the diagonal of D_1. Let $A_i \in \mathbb{R}^{n\times n^2}$ denote the matrix obtained by flattening A along the i-th direction, for each $i \in [3]$.

Define $U^* \in \mathbb{R}^{n\times k}$ to be the optimal solution to $\min_{U\in\mathbb{R}^{n\times k}} \|UB_1 - A_1\|_1$, $\widehat{U} = A_1 D_1 (B_1 D_1)^\dagger \in \mathbb{R}^{n\times k}$, $V_0 \in \mathbb{R}^{n\times k}$ to be the optimal solution to $\min_{V\in\mathbb{R}^{n\times k}} \|V \cdot (\widehat{U}^\top \odot W_B^\top) - A_2\|_1$, and U' to be the optimal solution to $\min_{U\in\mathbb{R}^{n\times k}} \|UB_1D_1 - A_1D_1\|_1$.

By Claim 21.3.4, we have

$$\|\widehat{U}B_1D_1 - A_1D_1\|_1 \leq \sqrt{d_1}\|U'B_1D_1 - A_1D_1\|_1$$

Due to Lemma D.11 and Lemma D.8 (in [SWZ17]) with constant probability, we have

$$\|\widehat{U}B_1 - A_1\|_1 \leq \sqrt{d_1}\alpha_{D_1}\|U^*B_1 - A_1\|_1, \tag{21.41}$$

where $\alpha_{D_1} = O(1)$.

Recall that $(\widehat{U}^\top \odot W_B^\top) \in \mathbb{R}^{k \times n^2}$ denotes the matrix where the i-th row is the vectorization of $\widehat{U}_i \otimes (W_B)_i$, $\forall i \in [k]$. Now, we can show,

$$\begin{aligned}
\|V_0 \cdot (\widehat{U}^\top \odot W_B^\top) - A_2\|_1 \leq \|\widehat{U} B_1 - A_1\|_1 & \quad \text{by } V_0 = \arg\min_{V \in \mathbb{R}^{n \times k}} \|V \cdot (\widehat{U}^\top \odot W_B^\top) - A_2\|_1 \\
\lesssim \sqrt{d_1} \|U^* B_1 - A_1\|_1 & \quad \text{by Equation (21.41)} \\
\leq \sqrt{d_1} \|U_B B_1 - A_1\|_1 & \quad \text{by } U^* = \arg\min_{U \in \mathbb{R}^{n \times k}} \|U B_1 - A_1\|_1 \\
\leq O(\sqrt{d_1}) \alpha \, \mathrm{OPT} & \quad \text{by Equation (21.40)}
\end{aligned} \tag{21.42}$$

We define $B_2 = \widehat{U}^\top \odot W_B^\top$. We can compute $D_2 \in \mathbb{R}^{n^2 \times n^2}$ which is a sampling and rescaling matrix corresponding to the Lewis weights of $B_2^\top$ in $O(n^2 \, \mathrm{poly}(k))$ time, and there are $d_2 = O(k \log k)$ nonzero entries on the diagonal of D_2.

Define $V^* \in \mathbb{R}^{n \times k}$ to be the optimal solution of $\min_{V \in \mathbb{R}^{n \times k}} \|V B_2 - A_2\|_1$, $\widehat{V} = A_2 D_2 (B_2 D_2)^\dagger \in \mathbb{R}^{n \times k}$, $W_0 \in \mathbb{R}^{n \times k}$ to be the optimal solution of $\min_{W \in \mathbb{R}^{n \times k}} \|W \cdot (\widehat{U}^\top \odot \widehat{V}^\top) - A_3\|_1$, and V' to be the optimal solution of $\min_{V \in \mathbb{R}^{n \times k}} \|V B_2 D_2 - A_2 D_2\|_1$.

By Claim 21.3.4, we have

$$\|\widehat{V} B_2 D_2 - A_2 D_2\|_1 \leq \sqrt{d_2} \|V' B_2 D_2 - A_2 D_2\|_1.$$

Due to Lemma D.11 and Lemma D.8(in [SWZ17]) with constant probability, we have

$$\|\widehat{V} B_2 - A_2\|_1 \leq \sqrt{d_2} \alpha_{D_2} \|V^* B_2 - A_2\|_1, \tag{21.43}$$

where $\alpha_{D_2} = O(1)$.

Recall that $(\widehat{U}^\top \odot \widehat{V}^\top) \in \mathbb{R}^{k \times n^2}$ denotes the matrix for which the i-th row is the

vectorization of $\widehat{U}_i \otimes \widehat{V}_i$, $\forall i \in [k]$. Now, we can show,

$$\begin{aligned}
\|W_0 \cdot (\widehat{U}^\top \odot \widehat{V}^\top) - A_3\|_1 &\leq \|\widehat{V} B_2 - A_2\|_1 && \text{by } W_0 = \arg\min_{W \in \mathbb{R}^{n \times k}} \|W \cdot (\widehat{U}^\top \odot \widehat{V}^\top) - A_3\|_1 \\
&\lesssim \sqrt{d_2} \|V^* B_2 - A_2\|_1 && \text{by Equation (21.43)} \\
&\leq \sqrt{d_2} \|V_0 B_2 - A_2\|_1 && \text{by } V^* = \arg\min_{V \in \mathbb{R}^{n \times k}} \|V B_2 - A_2\|_1 \\
&\leq O(\sqrt{d_1 d_2}) \alpha \, \mathrm{OPT} && \text{by Equation (21.42)}
\end{aligned} \tag{21.44}$$

We define $B_3 = \widehat{U}^\top \odot \widehat{V}^\top$. We can compute $D_3 \in \mathbb{R}^{n^2 \times n^2}$ which is a sampling and rescaling matrix corresponding to the Lewis weights of $B_3^\top$ in $O(n^2 \, \mathrm{poly}(k))$ time, and there are $d_3 = O(k \log k)$ nonzero entries on the diagonal of D_3.

Define $W^* \in \mathbb{R}^{n \times k}$ to be the optimal solution to $\min_{W \in \mathbb{R}^{n \times k}} \|W B_3 - A_3\|_1$, $\widehat{W} = A_3 D_3 (B_3 D_3)^\dagger \in \mathbb{R}^{n \times k}$, and W' to be the optimal solution to $\min_{W \in \mathbb{R}^{n \times k}} \|W B_3 D_3 - A_3 D_3\|_1$.

By Claim 21.3.4, we have

$$\|\widehat{W} B_3 D_3 - A_3 D_3\|_1 \leq \sqrt{d_3} \|W' B_3 D_3 - A_3 D_3\|_1.$$

Due to Lemma D.11 and Lemma D.8(in [SWZ17]) with constant probability, we have

$$\|\widehat{W} B_3 - A_3\|_1 \leq \sqrt{d_3} \alpha_{D_3} \|W^* B_3 - A_3\|_1, \tag{21.45}$$

where $\alpha_{D_3} = O(1)$. Now we can show,

$$\begin{aligned}
\|\widehat{W} B_3 - A_3\|_1 &\lesssim \sqrt{d_3} \|W^* B_3 - A_3\|_1, && \text{by Equation (21.45)} \\
&\leq \sqrt{d_3} \|W_0 B_3 - A_3\|_1, && \text{by } W^* = \arg\min_{W \in \mathbb{R}^{n \times k}} \|W B_3 - A_3\|_1 \\
&\leq O(\sqrt{d_1 d_2 d_3}) \alpha \, \mathrm{OPT} && \text{by Equation (21.44)}
\end{aligned}$$

Thus, it implies,

$$\left\| \sum_{i=1}^{k} \widehat{U}_i \otimes \widehat{V}_i \otimes \widehat{W}_i - A \right\|_1 \leq \mathrm{poly}(k, \log n)\, \mathrm{OPT}\,.$$

where $\widehat{U} = A_1 D_1 (B_1 D_1)^\dagger$, $\widehat{V} = A_2 D_2 (B_2 D_2)^\dagger$, $\widehat{W} = A_3 D_3 (B_3 D_3)^\dagger$.

21.8 Weighted Frobenius Norm for Arbitrary Tensors

This section presents several tensor algorithms for the weighted case. For notational purposes, instead of using U, V, W to denote the ground truth factorization, we use U_1, U_2, U_3 to denote the ground truth factorization. We use A to denote the input tensor, and W to denote the tensor of weights. Combining our new tensor techniques with existing weighted low rank approximation algorithms [RSW16] allows us to obtain several interesting new results. We provide some necessary definitions and facts in Section 21.8.1. Section 21.8.2 provides an algorithm when W has at most r distinct faces in each dimension. Section 21.8.3 studies relationships between r distinct faces and r distinct columns. Finally, we provides an algorithm with a similar running time but weaker assumption, where W has at most r distinct columns and r distinct rows in Section 21.8.4. The result in Theorem 21.8.2 is fairly similar to Theorem 21.8.5, except for the running time. We only put a very detailed discussion in the statement of Theorem 21.8.5. Note that Theorem 21.8.2 also has other versions which are similar to the Frobnius norm rank-k algorithms described in Section 21.1. For simplicity of presentation, we only present one clean and simple version (which assumes A_k exists and has factor norms which are not too large).

21.8.1 Definitions and Facts

For a matrix $A \in \mathbb{R}^{n\times m}$ and a weight matrix $W \in \mathbb{R}^{n\times m}$, we define $\|W \circ A\|_F$ as follows,

$$\|W \circ A\|_F = \left(\sum_{i=1}^{n} \sum_{j=1}^{m} W_{i,j}^2 A_{i,j}^2 \right)^{\frac{1}{2}}.$$

For a tensor $A \in \mathbb{R}^{n\times n\times n}$ and a weight tensor $W \in \mathbb{R}^{n\times n\times n}$, we define $\|W \circ A\|_F$ as follows,

$$\|W \circ A\|_F = \left(\sum_{i=1}^{n} \sum_{j=1}^{n} \sum_{l=1}^{n} W_{i,j,l}^2 A_{i,j,l}^2 \right)^{\frac{1}{2}}.$$

For three matrices $A \in \mathbb{R}^{n\times m}$, $U \in \mathbb{R}^{n\times k}$, $V \in \mathbb{R}^{k\times m}$ and a weight matrix W, from one perspective, we have

$$\|(UV - A) \circ W\|_F^2 = \sum_{i=1}^{n} \|(U^i V - A^i) \circ W^i\|_2^2 = \sum_{i=1}^{n} \|(U^i V - A^i) D_{W^i}\|_2^2,$$

where W^i denote the i-th row of matrix W, and $D_{W^i} \in \mathbb{R}^{m\times m}$ denotes a diagonal matrix where the j-th entry on diagonal is the j-th entry of vector W^i. From another perspective, we have

$$\|(UV - A) \circ W\|_F^2 = \sum_{j=1}^{m} \|(UV_j - A_j) \circ W_j\|_2^2 = \sum_{j=1}^{m} \|(UV_j - A_j) D_{W_j}\|_2^2,$$

where W_j denotes the j-th column of matrix W, and $D_{W_j} \in \mathbb{R}^{n\times n}$ denotes a diagonal matrix where the i-th entry on the diagonal is the i-th entry of vector W_j.

One of the key tools we use in this section is,

Lemma 21.8.1 (Cramer's rule)**.** *Let R be an $n \times n$ invertible matrix. Then, for each $i \in [n], j \in [n]$,*

$$(R^{-1})_i^j = \det(R_{\neg j}^{\neg i}) / \det(R),$$

where $R^{\neg i}_{\neg j}$ is the matrix R with the i-th row and the j-th column removed.

21.8.2 r distinct faces in each dimension

Notice that in the matrix case, it is sufficient to assume that $\|A'\|_F$ is upper bounded [RSW16]. Once we have that $\|A'\|_F$ is bounded, without loss of generality, we can assume that U_1^* is an orthonormal basis[CW15a, RSW16]. If U_1^* is not an orthonormal basis, then let $U_1'R$ denote a QR factorization of U_1^*, and then write $U_2' = RU_2^*$. However, in the case of tensors we have to assume that each factor $\|U_i^*\|_F$ is upper bounded due to border rank issues (see, e.g., [DSL08]).

Theorem 21.8.2. *Given a 3rd order $n \times n \times n$ tensor A and an $n \times n \times n$ tensor W of weights with r distinct faces in each of the three dimensions for which each entry can be written using $O(n^\delta)$ bits, for $\delta > 0$, define* $\mathrm{OPT} = \inf_{\mathrm{rank}-k\ A_k} \|W \circ (A_k - A)\|_F^2$. *Let $k \geq 1$ be an integer and let $0 < \epsilon < 1$.*

If $\mathrm{OPT} > 0$*, and there exists a rank-*k $A_k = U_1^* \otimes U_2^* \otimes U_3^*$ *tensor (with size* $n \times n \times n$*) such that* $\|W \circ (A_k - A)\|_F^2 = \mathrm{OPT}$*, and* $\max_{i \in [3]} \|U_i^*\|_F \leq 2^{O(n^\delta)}$*, then there exists an algorithm that takes* $(\mathrm{nnz}(A) + \mathrm{nnz}(W) + n2^{\widetilde{O}(rk^2/\epsilon)})n^{O(\delta)}$ *time in the unit cost* RAM *model with words of size* $O(\log n)$ *bits*[10] *and outputs three* $n \times k$ *matrices* U_1, U_2, U_3 *such that*

$$\|W \circ (U_1 \otimes U_2 \otimes U_3 - A)\|_F^2 \leq (1 + \epsilon)\,\mathrm{OPT} \tag{21.46}$$

holds with probability $9/10$*.*

Proof. Note that W has r distinct columns, rows, and tubes. Hence, each of the matrices $W_1, W_2, W_3 \in \mathbb{R}^{n \times n^2}$ has at most r distinct columns, and at most r distinct rows. Let $U_1^*, U_2^*, U_3^* \in \mathbb{R}^{n \times k}$ denote the matrices satisfying $\|W \circ (U_1^* \otimes U_2^* \otimes U_3^* - A)\|_F^2 = \mathrm{OPT}$. We fix U_2^* and U_3^*, and consider a flattening of the tensor along the first dimension,

$$\min_{U_1 \in \mathbb{R}^{n \times k}} \|(U_1 Z_1 - A_1) \circ W_1\|_F^2 = \mathrm{OPT},$$

where matrix $Z_1 = U_2^{*\top} \odot U_3^{*\top}$ has size $k \times n^2$ and for each $i \in [k]$ the i-th row of Z_1 is $\mathrm{vec}((U_2^*)_i \otimes (U_3^*)_i)$. For each $i \in [n]$, let W_1^i denote the i-th row of $n \times n^2$ matrix W_1. For each $i \in [n]$, let $D_{W_1^i}$ denote the diagonal matrix of size $n^2 \times n^2$, where each diagonal entry is from the vector $W_1^i \in \mathbb{R}^{n^2}$. Without loss of generality, we can assume the first r rows of W_1 are distinct. We can rewrite the objective function along the first dimension as a sum of multiple regression problems. For any $n \times k$ matrix U_1,

$$\|(U_1 Z_1 - A_1) \circ W_1\|_F^2 = \sum_{i=1}^{n} \|U_1^i Z_1 D_{W_1^i} - A_1^i D_{W_1^i}\|_2^2. \tag{21.47}$$

[10] The entries of A and W are assumed to fit in n^δ words.

Based on the observation that W_1 has r distinct rows, we can group the n rows of W^1 into r groups. We use $g_{1,1}, g_{1,2}, \cdots, g_{1,r}$ to denote r sets of indices such that, for each $i \in g_{1,j}$, $W_1^i = W_1^j$. Thus we can rewrite Equation (21.47),

$$\begin{aligned}\|(U_1 Z_1 - A_1) \circ W_1\|_F^2 &= \sum_{i=1}^{n} \|U_1^i Z_1 D_{W_1^i} - A_1^i D_{W_1^i}\|_2^2 \\ &= \sum_{j=1}^{r} \sum_{i \in g_{1,j}} \|U_1^i Z_1 D_{W_1^i} - A_1^i D_{W_1^i}\|_2^2.\end{aligned}$$

We can sketch the objective function by choosing Gaussian matrices $S_1 \in \mathbb{R}^{n^2 \times s_1}$ with $s_1 = O(k/\epsilon)$.

$$\sum_{i=1}^{n} \|U_1^i Z_1 D_{W_1^i} S_1 - A_1^i D_{W_1^i} S_1\|_2^2.$$

Let $\widehat{U}_1$ denote the optimal solution of the sketch problem,

$$\widehat{U}_1 = \arg\min_{U_1 \in \mathbb{R}^{n \times k}} \sum_{i=1}^{n} \|U_1^i Z_1 D_{W_1^i} S_1 - A_1^i D_{W_1^i} S_1\|_2^2.$$

By properties of S_1([RSW16]), plugging $\widehat{U} \in \mathbb{R}^{n \times k}$ into the original problem, we obtain,

$$\sum_{i=1}^{n} \|\widehat{U}_1^i Z_1 D_{W_1^i} - A_1^i D_{W_1^i}\|_2^2 \leq (1+\epsilon)\,\mathrm{OPT}\,.$$

Note that $\widehat{U}_1 \in \mathbb{R}^{n \times k}$ also has the following form. For each $i \in [n]$,

$$\begin{aligned}\widehat{U}_1^i &= A_1^i D_{W_1^i} S_1 (Z_1 D_{W_1^i} S_1)^\dagger \\ &= A_1^i D_{W_1^i} S_1 (Z_1 D_{W_1^i} S_1)^\top ((Z_1 D_{W_1^i} S_1)(Z_1 D_{W_1^i} S_1)^\top)^{-1}.\end{aligned}$$

Note that W_1 has r distinct rows. Thus, we only have r distinct $D_{W_1^i}$. This implies that there are r distinct matrices $Z_1 D_{W_1^i} S_1 \in \mathbb{R}^{k \times s_1}$. Using the definition of $g_{1,j}$, for $j \in [r]$, for

each $i \in g_{1,j} \subset [n]$, we have

$$\begin{aligned}\widehat{U}_1^i &= A_1^i D_{W_1^i} S_1 (Z_1 D_{W_1^i} S_1)^\dagger \\ &= A_1^i D_{W_1^j} S_1 (Z_1 D_{W_1^j} S_1)^\dagger \qquad \text{by } W_1^i = W_1^j,\end{aligned}$$

which means we only need to write down r different $Z_1 D_{W_1^j} S_1$. For each $k \times s_1$ matrix $Z_1 D_{W_1^j} S_1$, we create $k \times s_1$ variables to represent it. Thus, we need to create rks_1 variables to represent r matrices,

$$\{Z_1 D_{W_1^1} S_1, Z_1 D_{W_1^2} S_1, \cdots, Z_1 D_{W_1^r} S_1\}.$$

For simplicity, let $P_{1,i} \in \mathbb{R}^{k \times s_1}$ denote $Z_1 D_{W_1^i} S_1$. Then we can rewrite $\widehat{U}^i \in \mathbb{R}^k$ as follows,

$$\widehat{U}_1^i = A_1^i D_{W_1^i} S_1 P_{1,i}^\top (P_{1,i} P_{1,i}^\top)^{-1}.$$

If $P_{1,i} P_{1,i}^\top \in \mathbb{R}^{k \times k}$ has rank k, then we can use Cramer's rule (Lemma 21.8.1) to write down the inverse of $P_{1,i} P_{1,i}^\top$. However, vector W_1^i could have many zero entries. Then the rank of $P_{1,i} P_{1,i}^\top$ can be smaller than k. There are two different ways to solve this issue.

One way is by using the argument from [RSW16], which allows us to assume that $P_{1,i} P_{1,i}^\top \in \mathbb{R}^{k \times k}$ has rank k.

The other way is straightforward: we can guess the rank. There are k possibilities. Let $t_i \leq k$ denote the rank of $P_{1,i}$. Then we need to figure out a maximal linearly independent subset of rows of $P_{1,i}$. There are $2^{O(k)}$ possibilities. Next, we need to figure out a maximal linearly independent subset of columns of $P_{1,i}$. We can also guess all the possibilities, which is at most $2^{O(k)}$. Because we have r different $P_{1,i}$, the total number of guesses we have is at most $2^{O(rk)}$. Thus, we can write down $(P_{1,i} P_{1,i}^\top)^{-1}$ according to Cramer's rule.

After $\widehat{U}_1$ is obtained, we will fix $\widehat{U}_1$ and U_3^* in the next round. We consider the flattening of the tensor along the second direction,

$$\min_{U_2 \in \mathbb{R}^{n \times k}} \|(U_2 Z_2 - A_2) \circ W_2\|_F^2,$$

where $n \times n^2$ matrix A_2 is obtained by flattening tensor A along the second dimension, $k \times n^2$ matrix Z_2 denotes $\widehat{U}_1^\top \odot U_3^{*\top}$, and $n \times n^2$ matrix W_2 is obtained by flattening tensor W along the second dimension. For each $i \in [n]$, let W_2^i denote the i-th row of $n \times n^2$ matrix W_2. For each $i \in [n]$, let $D_{W_1^i}$ denote the diagonal matrix which has size $n^2 \times n^2$ and for which each entry is from vector $W_2^i \in \mathbb{R}^{n^2}$. Without loss of generality, we can assume the first r rows of W_2 are distinct. We can rewrite the objective function along the second dimension as a sum of multiple regression problems. For any $n \times k$ matrix U_2,

$$\|(U_2 Z_2 - A_2) \circ W_2\|_F^2 = \sum_{i=1}^n \|U_2^i Z_2 D_{W_2^i} - A_2^i D_{W_2^i}\|_2^2. \tag{21.48}$$

Based on the observation that W_2 has r distinct rows, we can group the n rows of W^2 into r groups. We use $g_{2,1}, g_{2,2}, \cdots, g_{2,r}$ to denote r sets of indices such that, for each $i \in g_{2,j}$, $W_2^i = W_2^j$. Thus we obtain,

$$\begin{aligned} \|(U_2 Z_2 - A_2) \circ W_2\|_F^2 = & \sum_{i=1}^n \|U_2^i Z_2 D_{W_2^i} - A_2^i D_{W_2^i}\|_2^2 \\ = & \sum_{j=1}^r \sum_{i \in g_{2,j}} \|U_2^i Z_2 D_{W_2^i} - A_2^i D_{W_2^i}\|_2^2. \end{aligned}$$

We can sketch the objective function by choosing a Gaussian sketch $S_2 \in \mathbb{R}^{n^2 \times s_2}$ with $s_2 = O(k/\epsilon)$. Let $\widehat{U}_2$ denote the optimal solution to the sketch problem. Then $\widehat{U}_2$ has the form, for each $i \in [n]$,

$$\widehat{U}_2^i = A_2^i D_{W_2^i} S_2 (Z_2 D_{W_2^i} S_2)^\dagger.$$

Similarly as before, we only need to write down r different matrices $Z_2 D_{W_2^i} S_1$, and for each of them, create $k \times s_2$ variables. Let $P_{2,i} \in \mathbb{R}^{k \times s_2}$ denote $Z_2 D_{W_2^i} S_2$. By our guessing argument, we can obtain $\widehat{U}_2$.

In the last round, we fix $\widehat{U}_1$ and $\widehat{U}_2$. We then write down $\widehat{U}_3$. Overall, by creating $l = O(rk^2/\epsilon)$ variables, we have rational polynomials $\widehat{U}_1(x)$, $\widehat{U}_2(x)$, $\widehat{U}_3(x)$. Putting it all together, we can write this objective function,

$$\begin{aligned} \min_{x \in \mathbb{R}^l} & \|(\widehat{U}_1(x) \otimes \widehat{U}_2(x) \otimes \widehat{U}_3(x) - A) \circ W\|_F^2. \\ \text{s.t. } & h_{1,i}(x) \neq 0, \forall i \in [r]. \\ & h_{2,i}(x) \neq 0, \forall i \in [r]. \\ & h_{3,i}(x) \neq 0, \forall i \in [r]. \end{aligned}$$

where $h_{1,i}(x)$ denotes the denominator polynomial related to a full rank sub-block of $P_{1,i}(x)$. By a perturbation argument in Section 4 in [RSW16], we know that the $h_{1,i}(x)$ are nonzero. By a similar argument as in Section 5 in [RSW16], we can show a lower bound on the cost of the denominator polynomial $h_{1,i}(x)$. Thus we can create new bounded variables $x_{l+1}, \cdots, x_{3r+l}$ to rewrite the objective function,

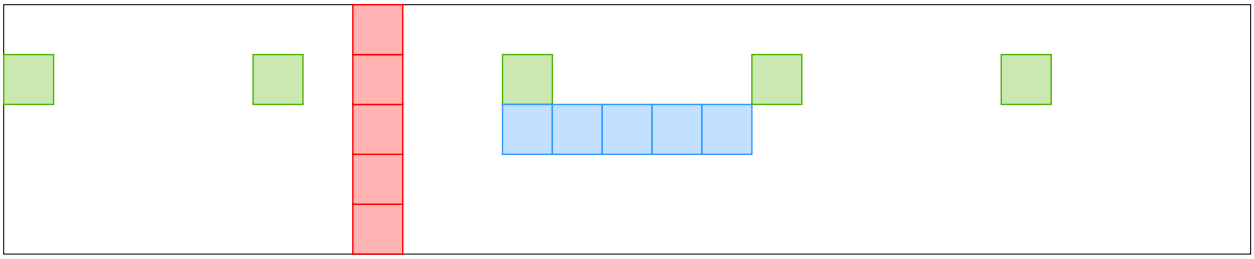
$$\begin{aligned}
\min_{x\in\mathbb{R}^{l+3r}} \; & q(x)/p(x). \\
\text{s.t. } & h_{1,i}(x)x_{l+i} = 0, \forall i \in [r]. \\
& h_{2,i}(x)x_{l+r+i} = 0, \forall i \in [r]. \\
& h_{3,i}(x)x_{l+2r+i} = 0, \forall i \in [r]. \\
& p(x) = \prod_{i=1}^{r} h_{1,i}^2(x)h_{2,i}^2(x)h_{3,i}^2(x)
\end{aligned}$$

Note that the degree of the above system is poly(kr) and all the equality constraints can be merged into one single constraint. Thus, the number of constraints is $O(1)$. The number of variables is $O(rk^2/\epsilon)$.

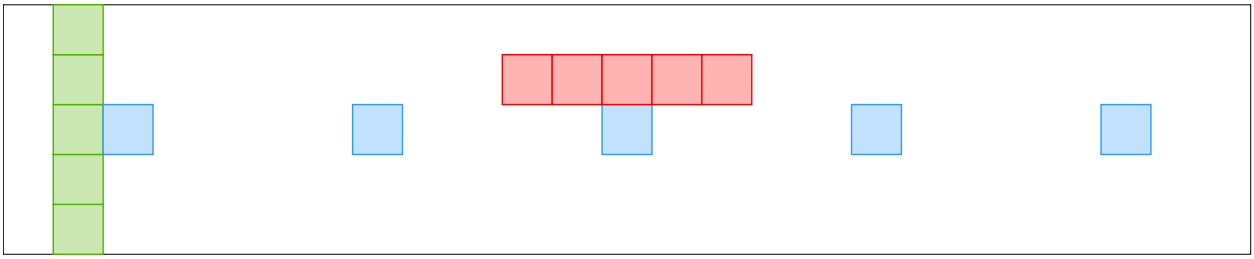
Using Theorem 21.3.2 and a similar argument from Section 5 of [RSW16], we have that the minimum nonzero cost is at least $2^{-n^\delta 2^{\widetilde{O}(rk^2/\epsilon)}}$. Combining the binary search explained in Section 21.4(similar techniques also can be found in Section 6 of [RSW16]) with the lower bound we obtained, we can find the solution for the original problem in time,

$$(\text{nnz}(A) + \text{nnz}(W) + n2^{\widetilde{O}(rk^2/\epsilon)})n^{O(\delta)}.$$

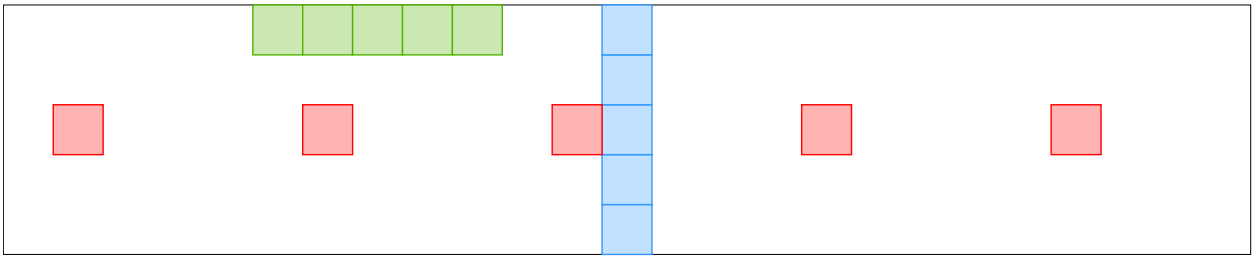
□



$(W_1)_{i,(j-1)n+l} = W_{i,j,l}$



$(W_2)_{j,(l-1)n+i} = W_{i,j,l}$



$(W_3)_{l,(i-1)n+j} = W_{i,j,l}$

Figure 21.7: Let W denote a tensor that has columns(red), rows(green) and tubes(blue). For each $i \in [3]$, let W_i denote the matrix obtained by flattening tensor W along the i-th dimension.

21.8.3 r distinct columns, rows and tubes

Lemma 21.8.3. *Let $W \in \mathbb{R}^{n \times n \times n}$ denote a tensor that has r distinct columns and r distinct rows, then W has*

(I) *r distinct column-tube faces.*

(II) *r distinct row-tube faces.*

Proof. Proof of Part (I). Without loss of generality, we consider the first (which is the bottom one) column-row face. Assume it has r distinct rows and r distinct columns. We can re-order all the column-tube faces to make sure that all the n columns in the bottom face have been split into r continuous disjoint groups C_i, e.g., $\{C_1, C_2, \cdots, C_r\} = [n]$. Next, we can re-order all the row-tube faces to make sure that all the n rows in the bottom face have been split into r continuous disjoint groups R_i, e.g., $\{R_1, R_2, \cdots, R_r\} = [n]$. Thus, the new bottom face can be regarded as $r \times r$ groups, and the number in each position of the same group is the same.

Suppose that the tensor has $r + 1$ distinct column-tube faces. By the pigeonhole principle there exist two different column-tube faces belonging to the same group C_i, for some $i \in [r]$. Note that these two column-tube faces are the same by looking at the bottom (column-row) face. Since they are distinct faces, there must exist one row vector v which is not in the bottom (column-row) face, and it has a different value in coordinates belong to group C_i. Note that, considering the bottom face, for each row vector, it has the same value over coordinates belonging to group C_i. But v has different values in coordinates belong to group C_i. Also, note that the bottom (column-row) face also has r distinct rows, and v is not one of them. This means there are at least $r + 1$ distinct rows, which contradicts that there are r distinct rows in total. Thus, there are at most r distinct column-tube faces.

Proof of Part (II). It is similar to Part (I). □

Corollary 21.8.4. *Let $W \in \mathbb{R}^{n \times n \times n}$ denote a tensor that has r distinct columns, r distinct rows, and r distinct rubes. Then W has r distinct column-tube faces, r distinct row-tube faces, and r distinct column-row faces.*

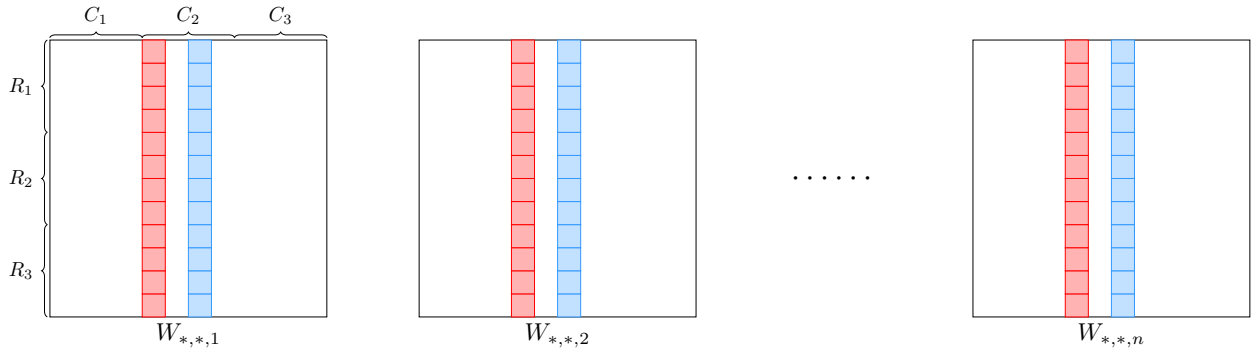


Figure 21.8: Each face $W_{*,*,i}$ is a column-row face. $W_{*,*,1}$ is the bottom column-row face. $r = 3$. The blue blocks represent column-tube faces, the red blocks represent column-tube faces.

Proof. This follows by applying Lemma 21.8.3 twice. □

Thus, we obtain the same result as in Theorem 21.8.2 by changing the assumption from r distinct faces in each dimension to r distinct columns, r distinct rows and r distinct tubes.

21.8.4 r distinct columns and rows

The main difference between Theorem 21.8.2 and Theorem 21.8.5 is the running time. The first one takes $2^{\widetilde{O}(rk^2/\epsilon)}$ time and the second one is slightly longer, $2^{\widetilde{O}(r^2k^2/\epsilon)}$. By Lemma 21.8.3, r distinct columns in two dimensions implies r distinct faces in two of the three kinds of faces. Thus, the following theorem also holds for r distinct columns in two dimensions.

Algorithm 21.32 Weighted Tensor Low-rank Approximation Algorithm when the Weighted Tensor has r Distinct Faces in Each of the Two Dimensions.

  return U_1, U_2, U_3
end procedure

Theorem 21.8.5. *Given a 3rd order $n \times n \times n$ tensor A and an $n \times n \times n$ tensor W of weights with r distinct faces in two dimensions (out of three dimensions) such that each entry can be written using $O(n^\delta)$ bits for some $\delta > 0$, define* $\mathrm{OPT} = \inf_{\mathrm{rank}-k\ A_k} \|W \circ (A_k - A)\|_F^2$.

For any $k \geq 1$ and any $0 < \epsilon < 1$.

(I) *If* $\mathrm{OPT} > 0$, *and there exists a rank-k* $A_k = U_1^* \otimes U_2^* \otimes U_3^*$ *tensor (with size* $n \times n \times n$*) such that* $\|W \circ (A_k - A)\|_F^2 = \mathrm{OPT}$, *and* $\max_{i \in [3]} \|U_i^*\|_F \leq 2^{O(n^\delta)}$, *then there exists an algorithm that takes* $(\mathrm{nnz}(A) + \mathrm{nnz}(W) + n2^{\widetilde{O}(r^2k^2/\epsilon)})n^{O(\delta)}$ *time in the unit cost* RAM *model with words of size* $O(\log n)$ *bits*[11] *and outputs three* $n \times k$ *matrices* U_1, U_2, U_3 *such that*

$$\|W \circ (U_1 \otimes U_2 \otimes U_3 - A)\|_F^2 \leq (1 + \epsilon)\,\mathrm{OPT} \tag{21.49}$$

holds with probability $9/10$.

(II) *If* $\mathrm{OPT} > 0$, A_k *does not exist, and there exist three* $n \times k$ *matrices* U_1', U_2', U_3' *where each entry can be written using* $O(n^\delta)$ *bits and* $\|W \circ (U_1' \otimes U_2' \otimes U_3' - A)\|_F^2 \leq (1 + \epsilon/2)\,\mathrm{OPT}$, *then we can find* U, V, W *such that* (21.49) *holds.*

(III) *If* $\mathrm{OPT} = 0$, A_k *exists, and there exists a solution* U_1^*, U_2^*, U_3^* *such that each entry of the matrix can be written using* $O(n^\delta)$ *bits, then we can obtain* (21.49).

(IV) *If* $\mathrm{OPT} = 0$, *and there exist three* $n \times k$ *matrices* U_1, U_2, U_3 *such that* $\max_{i \in [3]} \|U_i^*\|_F \leq 2^{O(n^\delta)}$ *and*

$$\|W \circ (U_1 \otimes U_2 \otimes U_3 - A)\|_F^2 \leq (1 + \epsilon)\,\mathrm{OPT} + 2^{-\Omega(n^\delta)}, \tag{21.50}$$

then we can output U_1, U_2, U_3 *such that* (21.50) *holds.*

(V) *Further if* A_k *exists, we can output a number* Z *for which* $\mathrm{OPT} \leq Z \leq (1+\epsilon)\,\mathrm{OPT}$.

For all the cases, the algorithm succeeds with probability at least $9/10$.

[11] The entries of A and W are assumed to fit in n^δ words.

Proof. By Lemma 21.8.3, we have W has r distinct column-tube faces and r distinct row-tube faces. By Claim 21.8.6, we know that W has $R = 2^{O(r \log r)}$ distinct column-row faces.

We use the same approach as in proof of Theorem 21.8.2 (which is also similar to Section 8 of [RSW16]) to create variables, write down the polynomial systems and add not equal constraints. Instead of having $3r$ distinct denominators as in the proof of Theorem 21.8.2, we have $2r + R$.

We create $l = O(rk^2/\epsilon)$ variables for $\{Z_1 D_{W_1^1} S_1, Z_1 D_{W_1^2} S_1, \cdots, Z_1 D_{W_1^r} S_1\}$. Then we can write down $\widehat{U}_1$ with r distinct denominators $g_i(x)$. Each $g_i(x)$ is non-zero in an optimal solution using the perturbation argument in Section 4 in [RSW16]. We create new variables x_{2l+i} to remove the denominators $g_i(x)$, $\forall i \in [r]$. Then the entries of $\widehat{U}_1$ are polynomials as opposed to rational functions.

We create $l = O(rk^2/\epsilon)$ variables for $\{Z_2 D_{W_2^1} S_2, Z_2 D_{W_2^2} S_2, \cdots, Z_2 D_{W_2^r} S_2\}$. Then we can write down $\widehat{U}_2$ with r distinct denominators $g_{r+i}(x)$. Each $g_{r+i}(x)$ is non-zero in an optimal solution using the perturbation argument in Section 4 in [RSW16]. We create new variables x_{2l+r+i} to remove the denominators $g_{r+i}(x)$, $\forall i \in [r]$. Then the entries of $\widehat{U}_2$ are polynomials as opposed to rational functions.

Using $\widehat{U}_1$ and $\widehat{U}_2$ we can express $\widehat{U}_3$ with R distinct denominators $f_i(x)$, which are also non-zero by using the perturbation argument in Section 4 in [RSW16], and using that W_3 has at most this number of distinct rows. Finally we can write the following optimization

problem,

$$\begin{aligned} \min_{x\in\mathbb{R}^{2l+2r}} \quad & p(x)/q(x) \\ \text{s.t.} \quad & g_i(x)x_{2l+i} - 1 = 0, \forall i \in [r] \\ & g_{r+i}(x)x_{2l+r+i} - 1 = 0, \forall i \in [r] \\ & f_j^2(x) \neq 0, \forall j \in [R] \\ & q(x) = \prod_{j=1}^{R} f_j^2(x) \end{aligned}$$

We then determine if there exists a solution to the above semi-algebraic set in time

$$(\mathrm{poly}(k,r)R)^{O(rk^2/\epsilon)} = 2^{\widetilde{O}(r^2k^2/\epsilon)}.$$

Using similar techniques from Section 5 of [RSW16], we can show a lower bound on the cost similar to Section 8.3 of [RSW16], namely, the minimum nonzero cost is at least

$$2^{-n^\delta 2^{\widetilde{O}(r^2k^2/\epsilon)}}.$$

Combining the binary search explained in Section 21.4 (a similar techniques also can be found in Section 6 of [RSW16]) with the lower bound we obtained, we can find a solution for the original problem in time

$$(\mathrm{nnz}(A) + \mathrm{nnz}(W) + n2^{\widetilde{O}(r^2k^2/\epsilon)})n^{O(\delta)}.$$

□

Remark 21.8.1. Note that the running time for the Frobenius norm and for the ℓ_1 norm are of the form $\mathrm{poly}(n) + \exp(\mathrm{poly}(k/\epsilon))$ rather than $\mathrm{poly}(n) \cdot \exp(k/\epsilon)$. The reason is, we can use an input sparsity reduction to reduce the size of the objective function from $\mathrm{poly}(n)$ to $\mathrm{poly}(k)$.

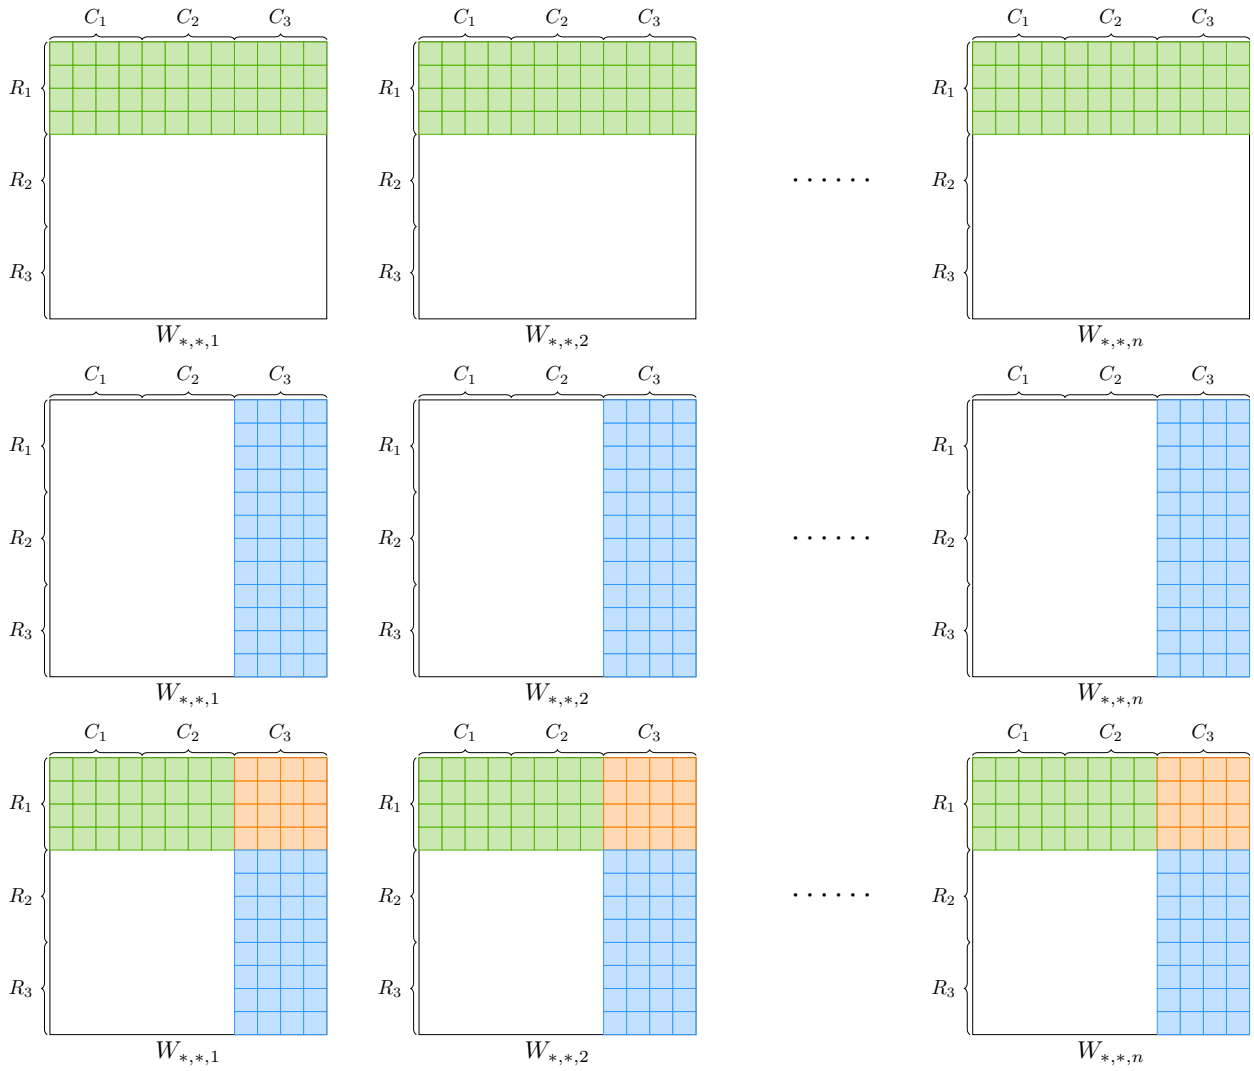

Figure 21.9: Each face $W_{*,*,i}$ is a column-row face. $W_{*,*,1}$ is the bottom column-row face. $r = 3$. The blue blocks represent $|C_3|$ column-tube faces. The green blocks represet $|R_3|$ row-tube faces. In each column-row face, the intersection between blue faces and green faces is a size $|R_3| \times |C_3|$ block, and all the entries in this block are the same.

Claim 21.8.6. *Let $W \in \mathbb{R}$ denote a third order tensor that has r distinct columns and r distinct rows. Then it has $2^{O(r \log r)}$ distinct column-row faces.*

Proof. By similar arguments as in the proof of Lemma 21.8.3, the bottom (column-row) face can be split into r groups $C_1, C_2, \cdots, C_r$ based on r columns, and split into r groups $R_1, R_2, \cdots, R_r$ based on rows. Thus, the bottom (column-row) face can be regarded as having $r \times r$ groups, and the number in each position of the same group is the same.

We can assume that all the r^2 blocks in the bottom column-row face have the same size. Otherwise, we can expand the tensor to the situation that all the r^2 blocks have the same size. Because this small tensor is a sub-tensor of the big tensor, if the big tensor has at most t distinct column-row faces, then the small tensor has at most t distinct column-row faces.

By Lemma 21.8.3, we know that the tensor W has at most r distinct column-tube faces and row-tube faces. Because it has r distinct column-tube faces, then all the faces belonging to coordinates in C_r are the same. Thus, all the columns belonging to C_r and in the second column-row face are the same. Similarly, we have that all the rows belonging to R_r and in the second column-row face are the same. Thus we have that all the entries in block $C_R \cup R_r$ and in the second column-row faces are the same. Further, we can conclude, for every column-row face, for every $C_i \cup R_j$ block, all the entries in the same block are the same.

The next observation is, if there exist $r^2 + 1$ different values in the tensor, then there exist either r distinct columns or r distinct rows. Indeed, otherwise since we have r distinct columns, each column has at most r distinct entries given our bound on the nunber of distinct rows. Thus, the r distinct columns could have at most r^2 distinct entries in total, a contradiction.

For each column-row face, there are at most r^2 blocks, and the value in each block can have at most r^2 possibilities. Thus, overall we have at most $(r^2)^{r^2} = 2^{O(r^2 \log r)}$ column-row faces.

By using different argument, we can improve the above bound. Note that we already show in each column-row face of a tensor, it has r^2 blocks, and all the values in each block have to be the same. Since we have r distinct rows, we can fix the those r distinct rows. If we copy row v into one row of R_i, then we have to copy row v into every row of R_i. This is because if R_i contains two distinct rows, then there must exist a block C_j for which the entries in block $R_i \cup C_j$ are not all the same. Thus, for each row group, all the rows in that group are the same.

Now, for each column-row face, consider the leftmost r blocks, $R_1 \cup C_1$, $R_2 \cup C_1$, $\cdots$, $R_r \cup C_1$. There are at most r possible values in each block, because we have r distinct rows in total. Overall the total number of possibilities for the leftmost r blocks is at most $(r)^r = 2^{O(r \log r)}$. Once the leftmost r blocks are determined, the remaining $r(r-1)$ are also determined. This completes the proof.

□

Also, notice that there is an example that has $2^{\Omega(r \log r)}$ distinct column-row faces. For the bottom column-row faces, there are $r \times r$ blocks for which all the blocks have the same size, the blocks on the diagonal have all 1s, and all the other blocks contain 0s everywhere. For the later column-row faces, we can arbitrarily permute this block diagonal matrix, and the total number of possibilities is $\Omega(r!) \geq 2^{\Omega(r \log r)}$.

21.9 Hardness

We first provide definitions and results for some fundamental problems in Section 21.9.1. Section 21.9.2 presents our hardness result for the symmetric tensor eigenvalue problem. Section 21.9.3 presents our hardness results for symmetric tensor singular value problems, computing tensor spectral norm, and rank-1 approximation. We improve Håstad's NP-hardness[Hås90] result for tensor rank in Section 21.9.4.

21.9.1 Definitions

We first provide the definitions for 3SAT , ETH , MAX-3SAT , MAX-E3SAT and then state some fundamental results related to those definitions.

Definition 21.9.1 (3SAT problem)**.** Given n variables and m clauses in a conjunctive normal form CNF formula with the size of each clause at most 3, the goal is to decide whether there exists an assignment to the n Boolean variables to make the CNF formula be satisfied.

Hypothesis 21.9.1 (Exponential Time Hypothesis (ETH) [IPZ98])**.** *There is a $\delta > 0$ such that the* 3SAT *problem defined in Definition 21.9.1 cannot be solved in $O(2^{\delta n})$ time.*

Definition 21.9.2 (MAX-3SAT)**.** Given n variables and m clauses, a conjunctive normal form CNF formula with the size of each clause at most 3, the goal is to find an assignment that satisfies the largest number of clauses.

We use MAX-E3SAT to denote the version of MAX-3SAT where each clause contains exactly 3 literals.

Theorem 21.9.2 ([Hås01])**.** *For every $\delta > 0$, it is* NP*-hard to distinguish a satisfiable instance of* MAX-E3SAT *from an instance where at most a $7/8 + \delta$ fraction of the clauses can be simultaneously satisfied.*

Theorem 21.9.3 ([Hås01, MR10])**.** *Assume* ETH *holds. For every $\delta > 0$, there is no $2^{o(n^{1-o(1)})}$ time algorithm to distinguish a satisfiable instance of* MAX-E3SAT *from an instance where at most a fraction $7/8 + \delta$ of the clauses can be simultaneously satisfied.*

We use MAX-E3SAT(B) to denote the restricted special case of MAX-3SAT where every variable occurs in at most B clauses. Håstad [Hås00] proved that the problem is

approximable to within a factor $7/8 + 1/(64B)$ in polynomial time, and that it is hard to approximate within a factor $7/8 + 1/(\log B)^{\Omega(1)}$. In 2001, Trevisan improved the hardness result,

Theorem 21.9.4 ([Tre01])**.** *Unless* **RP**=**NP**, *there is no polynomial time* $(7/8 + 5/\sqrt{B})$*-approximate algorithm for* MAX-E3SAT(B) .

Theorem 21.9.5 ([Hås01, Tre01, MR10])**.** *Unless* ETH *fails, there is no* $2^{o(n^{1-o(1)})}$ *time* $(7/8 + 5/\sqrt{B})$*-approximate algorithm for* MAX-E3SAT(B) .

Theorem 21.9.6 ([LMS11])**.** *Unless* ETH *fails, there is no* $2^{o(n)}$ *time algorithm for the Independent Set problem.*

Definition 21.9.3 (MAX-CUT decision problem)**.** Given a positive integer c^* and an unweighted graph $G = (V, E)$ where V is the set of vertices of G and E is the set of edges of G, the goal is to determine whether there is a cut of G that has at least c^* edges.

Note that Feige's original assumption[Fei02] states that there is no polynomial time algorithm for the problem in Assumption 21.9.7. We do not know of any better algorithm for the problem in Assumption 21.9.7 and have consulted several experts[12] about the assumption who do not know a counterexample to it.

Assumption 21.9.7 (Random Exponential Time Hypothesis)**.** *Let* $c > \ln 2$ *be a constant. Consider a random* 3SAT *formula on* n *variables in which each clause has* 3 *literals, and in which each of the* $8n^3$ *clauses is picked independently with probability* c/n^2*. Then any*

[12]Personal communication with Russell Impagliazzo and Ryan Williams.

algorithm which always outputs 1 *when the random formula is satisfiable, and outputs* 0 *with probability at least* $1/2$ *when the random formula is unsatisfiable, must run in* $2^{c'n}$ *time on some input, where* $c' > 0$ *is an absolute constant.*

The 4SAT-version of the above random-ETH assumption has been used in [GL04] and [RSW16] (Assumption 1.3).

21.9.2 Symmetric tensor eigenvalue

Definition 21.9.4 (Tensor Eigenvalue [HL13])**.** An eigenvector of a tensor $A \in \mathbb{R}^{n\times n\times n}$ is a nonzero vector $x \in \mathbb{R}^n$ such that

$$\sum_{i=1}^{n}\sum_{j=1}^{n} A_{i,j,k}x_ix_j = \lambda x_k, \forall k \in [n]$$

for some $\lambda \in \mathbb{R}$, which is called an eigenvalue of A.

Theorem 21.9.8 ([N+03])**.** *Let $G = (V, E)$ on v vertices have stability number (the size of a maximum independent set) $\alpha(G)$. Let $n = v + \frac{v(v-1)}{2}$ and $\mathbb{S}^{n-1} = \{(x, y) \in \mathbb{R}^v \times \mathbb{R}^{v(v-1)/2} : \|x\|_2^2 + \|y\|_2^2 = 1\}$. Then,*

$$\sqrt{1 - \frac{1}{\alpha(G)}} = 3\sqrt{3/2} \max_{(x,y)\in\mathbb{S}^{n-1}} \sum_{i<j,(i,j)\notin E} x_ix_jy_{i,j}.$$

For any graph $G(V, E)$, we can construct a symmetric tensor $A \in \mathbb{R}^{n\times n\times n}$. For any $1 \le i < j < k \le v$, let

$$A_{i,j,k} = \begin{cases} 1 & 1 \le i < j \le v, k = v + \phi(i, j), (i, j) \notin E, \\ 0 & \text{otherwise,} \end{cases}$$

where $\phi(i, j) = (i-1)v - i(i-1)/2 + j - i$ is a lexicographical enumeration of the $v(v-1)/2$ pairs $i < j$. For the other cases $i < k < j, \cdots, k < j < i$, we set

$$A_{i,j,k} = A_{i,k,j} = A_{j,i,k} = A_{j,k,i} = A_{k,i,j} = A_{k,j,i}.$$

If two or more indices are equal, we set $A_{i,j,k} = 0$. Thus tensor T has the following property,

$$A(z, z, z) = 6 \sum_{i<j,(i,j)\notin E} x_ix_jy_{i,j},$$

where $z = (x, y) \in \mathbb{R}^n$.

Thus, we have

$$\lambda = \max_{z \in \mathbb{S}^{n-1}} A(z,z,z) = \max_{(x,y) \in \mathbb{S}^{n-1}} 6 \sum_{i<j,(i,j) \notin E} x_i x_j y_{i,j}.$$

Furthermore, λ is the maximum eigenvalue of A.

Theorem 21.9.9. *Unless* ETH *fails, there is no* $2^{o(\sqrt{n})}$ *time to approximate the largest eigenvalue of an* n*-dimensional symmetric tensor within* $(1 \pm \Theta(1/n))$ *relative error.*

Proof. The additive error is at least

$$\sqrt{1-1/v} - \sqrt{1-1/(v-1)} = \frac{1/(v-1) - 1/v}{\sqrt{1-1/v} + \sqrt{1-1/(v-1)}} \gtrsim 1/(v-1) - 1/v \geq 1/v^2.$$

Thus, the relative error is $(1 \pm \Theta(1/v^2))$. By the definition of n, we know $n = \Theta(v^2)$. Assuming ETH , there is no $2^{o(v)}$ time algorithm to compute the clique number of $\overline{G}$. Because the clique number of $\overline{G}$ is $\alpha(G)$, there is no $2^{o(v)}$ time algorithm to compute $\alpha(G)$. Furthermore, there is no $2^{o(v)}$ time algorithm to approximate the maximum eigenvalue within $(1 \pm \Theta(1/v^2))$ relative error. Thus, we complete the proof. □

Corollary 21.9.10. *Unless* ETH *fails, there is no polynomial running time algorithm to approximate the largest eigenvalue of an* n*-dimensional tensor within* $(1 \pm \Theta(1/\log^{2+\gamma}(n)))$ *relative-error, where* $\gamma > 0$ *is an arbitrarily small constant.*

Proof. We can apply a padding argument here. According to Theorem 21.9.9, there is a d-dimensional tensor such that there is no $2^{o(\sqrt{d})}$ time algorithm that can give a $(1 + \Theta(1/d))$ relative error approximation. If we pad 0s everywhere to extend the size of the tensor

to $n = 2^{d^{(1-\gamma')/2}}$, where $\gamma' > 0$ is a sufficiently small constant, then $\text{poly}(n) = 2^{o(\sqrt{d})}$, so $d = \log^{2+O(\gamma')}(n)$. Thus, it means that there is no polynomial running time algorithm which can output a $(1 + 1/(\log^{2+\gamma}))$-relative approximation to the tensor which has size n.

□

21.9.3 Symmetric tensor singular value, spectral norm and rank-1 approximation

[HL13] defines two kinds of singular values of a tensor. In this paper, we only consider the following kind:

Definition 21.9.5 (ℓ_2 singular value in [HL13])**.** Given a 3rd order tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, the number $\sigma \in \mathbb{R}$ is called a singular value and the nonzero $u \in \mathbb{R}^{n_1}$,$v \in \mathbb{R}^{n_2}$,$w \in \mathbb{R}^{n_3}$ are called singular vectors of A if

$$\begin{aligned}
\sum_{j=1}^{n_2}\sum_{k=1}^{n_3} A_{i,j,k} v_j w_k &= \sigma u_i, \forall i \in [n_1] \\
\sum_{i=1}^{n_1}\sum_{k=1}^{n_3} A_{i,j,k} u_i w_k &= \sigma v_j, \forall j \in [n_2] \\
\sum_{i=1}^{n_1}\sum_{j=1}^{n_2} A_{i,j,k} u_i v_j &= \sigma w_k, \forall k \in [n_3].
\end{aligned}$$

Definition 21.9.6 (Spectral norm [HL13])**.** The spectral norm of a tensor A is:

$$\|A\|_2 = \sup_{x,y,z \neq 0} \frac{|A(x,y,z)|}{\|x\|_2 \|y\|_2 \|z\|_2}$$

Notice that the spectral norm is the absolute value of either the maximum value of $\frac{A(x,y,z)}{\|x\|_2\|y\|_2\|z\|_2}$ or the minimum value of it. Thus, it is an ℓ_2-singular value of A. Furthermore, it is the maximum ℓ_2-singular value of A.

Theorem 21.9.11 ([Ban38])**.** *Let $A \in \mathbb{R}^{n \times n \times n}$ be a symmetric 3rd order tensor. Then,*

$$\|A\|_2 = \sup_{x,y,z \neq 0} \frac{A(x,y,z)}{\|x\|_2 \|y\|_2 \|z\|_2} = \sup_{x \neq 0} \frac{|A(x,x,x)|}{\|x\|_2^3}.$$

It means that if a tensor is symmetric, then its largest eigenvalue is the same as its largest singular value and its spectral norm. Then, by combining with Theorem 21.9.9, we have the following corollary:

Corollary 21.9.12. *Unless* ETH *fails,*

1. *There is no $2^{o(\sqrt{n})}$ time algorithm to approximate the largest singular value of an n-dimensional symmetric tensor within $(1 + \Theta(1/n))$ relative-error.*

2. *There is no $2^{o(\sqrt{n})}$ time algorithm to approximate the spectral norm of an n-dimensional symmetric tensor within $(1 + \Theta(1/n))$ relative-error.*

By Corollary 21.9.10, we have:

Corollary 21.9.13. *Unless* ETH *fails,*

1. *There is no polynomial time algorithm to approximate the largest singular value of an n-dimensional tensor within $(1 + \Theta(1/\log^{2+\gamma}(n)))$ relative-error, where $\gamma > 0$ is an arbitrarily small constant.*

2. *There is no polynomial time algorithm to approximate the spectral norm of an n-dimensional tensor within $(1 + \Theta(1/\log^{2+\gamma}(n)))$ relative-error, where $\gamma > 0$ is an arbitrarily small constant.*

Now, let us consider Frobenius norm rank-1 approximation.

Theorem 21.9.14 ([Ban38])**.** *Let $A \in \mathbb{R}^{n \times n \times n}$ be a symmetric 3rd order tensor. Then,*

$$\min_{\sigma \geq 0, \|u\|_2 = \|v\|_2 = \|w\|_2 = 1} \|A - \sigma u \otimes v \otimes w\|_F = \min_{\lambda \geq 0, \|v\|_2 = 1} \|A - \lambda v \otimes v \otimes v\|_F.$$

Furthermore, the optimal σ and λ may be chosen to be equal.

Notice that

$$\|A - \sigma u \otimes v \otimes w\|_F^2 = \|A\|_F^2 - 2\sigma A(u, v, w) + \sigma^2 \|u \otimes v \otimes w\|_F^2.$$

Then, if $\|u\|_2 = \|v\|_2 = \|w\|_2 = 1$, we have:

$$\|A - \sigma u \otimes v \otimes w\|_F^2 = \|A\|_F^2 - 2\sigma A(u, v, w) + \sigma^2.$$

When $A(u, v, w) = \sigma$, then the above is minimized.

Thus, we have:

$$\min_{\sigma \geq 0, \|u\|_2 = \|v\|_2 = \|w\|_2 = 1} \|A - \sigma u \otimes v \otimes w\|_F^2 + \|A\|_2^2 = \|A\|_F^2.$$

It is sufficient to prove the following theorem:

Theorem 21.9.15. *Given $A \in \mathbb{R}^{n \times n \times n}$, unless* ETH *fails, there is no $2^{o(\sqrt{n})}$ time algorithm to compute $u', v', w' \in \mathbb{R}^n$ such that*

$$\|A - u' \otimes v' \otimes w'\|_F^2 \leq (1 + \epsilon) \min_{u, v, w \in \mathbb{R}^n} \|A - u \otimes v \otimes w\|_F^2,$$

where $\epsilon = O(1/n^2)$.

Proof. Let $A \in \mathbb{R}^{n \times n \times n}$ be the same hard instance mentioned in Theorem 21.9.8. Notice that each entry of A is either 0 or 1. Thus, $\min_{u,v,w \in \mathbb{R}^n} \|A - u \otimes v \otimes w\|_F^2 \leq \|A\|_F^2$. Notice that Theorem 21.9.8 also implies that it is hard to distinguish the two cases $\|A\|_2 \leq 2\sqrt{2/3} \cdot \sqrt{1 - 1/c}$ or $\|A\|_2 \geq 2\sqrt{2/3} \cdot \sqrt{1 - 1/(c+1)}$ where c is an integer which is no greater than $\sqrt{n}$. So the difference between $(2\sqrt{2/3} \cdot \sqrt{1 - 1/c})^2$ and $(2\sqrt{2/3} \cdot \sqrt{1 - 1/(c+1)})^2$ is at

least $\Theta(1/n)$. Since $\|A\|_F^2$ is at most n (see construction of A in the proof of Lemma 21.9.8), $\Theta(1/n)$ is an $\epsilon = O(1/n^2)$ fraction of $\min_{u,v,w\in\mathbb{R}^n} \|A - u\otimes v\otimes w\|_F^2$. Because

$$\min_{u,v,w\in\mathbb{R}^n} \|A - u\otimes v\otimes w\|_F^2 + \|A\|_2^2 = \|A\|_F^2,$$

if we have a $2^{o(\sqrt{n})}$ time algorithm to compute $u', v', w' \in \mathbb{R}^n$ such that

$$\|A - u'\otimes v'\otimes w'\|_F^2 \leq (1+\epsilon) \min_{u,v,w\in\mathbb{R}^n} \|A - u\otimes v\otimes w\|_F^2$$

for $\epsilon = O(1/n^2)$, it will contradict the fact that we cannot distinguish whether $\|A\|_2 \leq 2\sqrt{2/3}\cdot\sqrt{1-1/c}$ or $\|A\|_2 \geq 2\sqrt{2/3}\cdot\sqrt{1-1/(c+1)}$. □

Corollary 21.9.16. *Given $A \in \mathbb{R}^{n\times n\times n}$, unless* ETH *fails, for any ϵ for which $\frac{1}{2} \geq \epsilon \geq c/n^2$ where c is any constant, there is no $2^{o(\epsilon^{-1/4})}$ time algorithm to compute $u', v', w' \in \mathbb{R}^n$ such that*

$$\|A - u'\otimes v'\otimes w'\|_F^2 \leq (1+\epsilon) \min_{u,v,w\in\mathbb{R}^n} \|A - u\otimes v\otimes w\|_F^2.$$

Proof. If $\epsilon = \Omega(1/n^2)$, it means that $n = \Omega(1/\sqrt{\epsilon})$. Then, we can construct a hard instance B with size $m\times m\times m$ where $m = \Theta(1/\sqrt{\epsilon})$, and we can put B into A, and let A have zero entries elsewhere. Since B is hard, i.e., there is no $2^{o(m^{-1/2})} = 2^{o(\epsilon^{-1/4})}$ running time to compute a rank-1 approximation to B, this means there is no $2^{o(\epsilon^{-1/4})}$ running time algorithm to find an approximate rank-1 approximation to A. □

Corollary 21.9.17. *Unless* ETH *fails, there is no polynomial time algorithm to approximate the best rank-1 approximation of an n-dimensional tensor within $(1+\Theta(1/\log^{2+\gamma}(n)))$ relative-error, where $\gamma > 0$ is an arbitrarily small constant.*

Proof. We can apply a padding argument here. According to Theorem 21.9.15, there is a d-dimensional tensor such that there is no $2^{o(\sqrt{d})}$ time algorithm which can give a $(1+\Theta(1/d^4))$ relative approximation. Then, if we pad with 0s everywhere to extend the size of the tensor to $n = 2^{d^{(1-\gamma')/2}}$ where $\gamma' > 0$ is a sufficiently small constant, then $\text{poly}(n) = 2^{o(\sqrt{d})}$, and $d^4 = \log^{2+O(\gamma')}(n)$. Thus, it means that there is no polynomial time algorithm which can output a $(1 + 1/(\log^{2+\gamma}))$-relative error approximation to the tensor which has size n. □

21.9.4 Tensor rank is hard to approximate

This section presents the hardness result for approximating tensor rank under ETH . According to our new result, we notice that not only deciding the tensor rank is a hard problem, but also approximating the tensor rank is a hard problem. This therefore strengthens Håstad's NP-Hadness [Hås90] for computing tensor rank.

21.9.4.1 Cover number

Before getting into the details of the reduction, we provide a definition of an important concept called the "cover number" and discuss the cover number for the MAX-E3SAT(B) problem.

Definition 21.9.7 (Cover number)**.** For any 3SAT instance S with n variables and m clauses, we are allowed to assign one of three values $\{0, 1, *\}$ to each variable. For each clause, if one of the literals outputs true, then the clause outputs true. For each clause, if the corresponding variable of one of the literals is assigned to $*$, then the clause outputs true. We say $y \in \{0,1\}^n$ is a string, and $z \in \{0, 1, *\}^n$ is a star string. For an instance S, if there exists a string $y \in \{0,1\}^n$ that causes all the clauses to be true, then we say that S is satisfiable, otherwise it is unsatisfiable. For an instance S, let Z_S denote the set of star strings which cause all of the clauses of S to be true. For each star string $z \in \{0, 1, *\}^n$, let star(z) denote the number of $*$s in the star-string z. We define the "cover number" of instance S to be

$$\text{cover-number}(S) = \min_{z \in Z_S} \text{star}(z).$$

Notice that for a satisfiable 3SAT instance S, the cover number p is 0. Also, for any

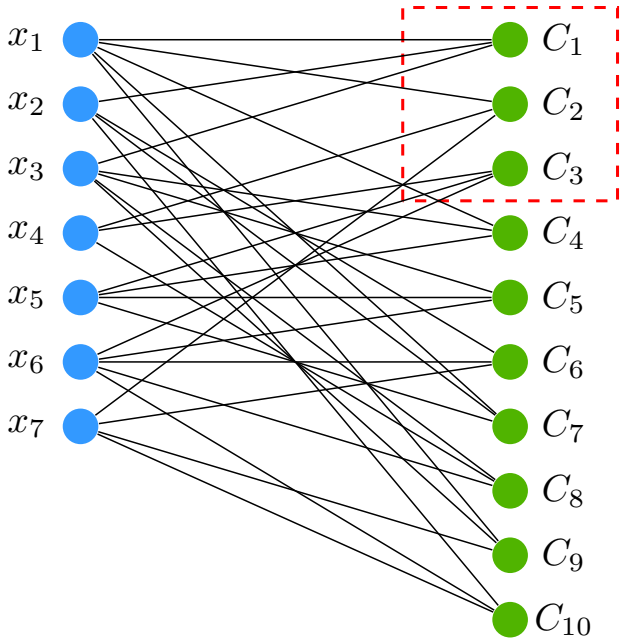

Figure 21.10: Cover number. For a 3SAT instance with n variables and m clauses, we can draw a bipartite graph which has n nodes on the left and m nodes on the right. Each node (blue) on the left corresponds to a variable x_i, each node (green) on the right corresponds to a clause C_j. If either x_i or $\overline{x}_i$ belongs to clause C_j, then we draw a line between these two nodes. Consider an input string $y \in \{0,1\}^7$. There exists some unsatisfied clauses with respect to this input string y. For for example, let C_1, C_2 and C_3 denote those unsatisfied clauses. We want to pick a smallest set of nodes on the left partition of the graph to guarantee that for each unsatisfied clause in the right partition, there exists a node on the left to cover it. The cover number is defined to be the smallest such number over all possible input strings.

unsatisfiable 3SAT instance S, the cover number p is at least 1. This is because for any input string, there exists at least one clause which cannot be satisfied. To fix that clause, we have to assign $*$ to a variable belonging to that clause. (Assigning $*$ to a variable can be regarded as assigning both 0 and 1 to a variable)

Lemma 21.9.18. *Let S denote a* MAX-E3SAT(B) *instance with n variables and m clauses and S suppose S is at most $7/8 + A$ satisfiable, where $A \in (0, 1/8)$. Then the cover number*

of S is at least $(1/8 - A)m/B$.

Proof. For any input string $y \in \{0,1\}^n$, there exists at least $(1/8 - A)m$ clauses which are not satisfied. Since each variable appears in at most B clauses, we need to assign $*$ to at least $(1/8 - A)m/B$ variables. Thus, the cover number of S is at least $(1/8 - A)m/B$. □

We say $x_1, x_2, \cdots, x_n$ are variables and $x_1, \overline{x}_1, x_2, \overline{x}_2, \cdots, x_n, \overline{x}_n$ are literals.

Definition 21.9.8. For a list of clauses C and a set of variables P, if for each clause, there exists at least one literal such that the corresponding variable of that literal belongs to P, then we say P covers L.

21.9.4.2 Properties of 3SAT instances

Fact 21.9.19. *For any* 3SAT *instance S with n variables and $m = \Theta(n)$ clauses, let $c > 0$ denote a constant. If S is $(1-c)m$ satisfiable, then let $y \in \{0,1\}^n$ denote a string for which S has the smallest number of unsatisfiable clauses. Let T denote the set of unsatisfiable clauses and let b denote the number of variables in T. Then $\Omega((cm)^{1/3}) \leq b \leq O(cm)$.*

Proof. Note that in S, there is no duplicate clause. Let T denote the set of unsatisfiable clauses by assigning string y to S. First, we can show that any two literals $x_i, \overline{x}_i$ cannot belong to T at the same time. If x_i and $\overline{x}_i$ belong to the same clause, then that clause must be an "always" satisfiable clause. If x_i and $\overline{x}_i$ belong to different clauses, then one of the clauses must be satisfiable. This contradicts the fact that that clause belongs to T. Thus, we can assume that literals $x_1, x_2, \cdots, x_b$ belong to T.

There are two extreme cases: one is that each clause only contains three literals and each literal appears in exactly one clause in T. Then $b = 3cm$. The other case is that each clause contains 3 literals, and each literal appears in as many clauses as possible. Then $\binom{b}{3} = cm$, which gives $b = \Theta((cm)^{1/3})$. □

Lemma 21.9.20. *For a random* 3SAT *instance, with probability* $1 - 2^{-\Omega(\log n \log\log n)}$ *there is no literal appearing in at least* $\log n$ *clauses.*

Proof. By the property of random 3SAT , for any literal x and any clause C, the probability that x appears in C is $\frac{3}{2n}$, i.e., $\Pr[x \in C] = \frac{3}{2n} = \Theta(1/n)$. Let p denote this probability. For any literal x, the probability of x appearing in at least $\log n$ clauses (out of m clauses) is

$$
\begin{aligned}
& \Pr[\ x \text{ appearing in} \geq \log n \text{ clauses }] \\
= & \sum_{i=\log n}^{m} \binom{m}{i} p^i (1-p)^{m-i} \\
= & \sum_{i=\log n}^{m/2} \binom{m}{i} p^i (1-p)^{m-i} + \sum_{i=m/2}^{m} \binom{m}{i} p^i (1-p)^{m-i} \\
\leq & \sum_{i=\log n}^{m/2} (em/i)^i p^i + \sum_{i=m/2}^{m} \binom{m}{i} p^i \qquad \text{by } (1-p) \leq 1, \binom{m}{i} \leq (em/i)^i \\
\leq & (\Theta(1/\log n))^{\log n} + 2 \cdot (2e)^{m/2} \cdot \Theta(1/n)^{m/2} \\
\leq & 2^{-\Omega(\log n \cdot \log\log n)}.
\end{aligned}
$$

Taking a union bound over all the literals, we complete the proof,

$$\Pr[\ \nexists\ x \text{ appearing in} \geq \log n \text{ clauses }] \geq 1 - 2^{-\Omega(\log n \log\log n)}.$$

□

Lemma 21.9.21. *For a sufficiently large constant $c' > 0$ and a constant $c > 0$, for any random* 3SAT *instance which has n variables and $m = c'n$ clauses, suppose it is $(1-c)m$ satisfiable. Then with probability $1 - 2^{-\Omega(\log n \log\log n)}$, for all input strings y, among the unsatisfied clauses, each literal appears in $O(\log n)$ places.*

Proof. This follows by Lemma 21.9.20. □

Next, we show how to reduce the $O(\log n)$ to $O(1)$.

Lemma 21.9.22. *For a sufficiently large constant c, for any random* 3SAT *instance that has n variables and $m = cn$ clauses, for any constant $B \geq 1, b \in (0,1)$, with probability at least $1 - \frac{9m}{Bbn}$, there exist at least $(1-b)m$ clauses such that each variable (in these $(1-b)m$ clauses) only appears in at most B clauses (out of these $(1-b)m$ clauses).*

Proof. For each $i \in [m]$, we use z_i to denote the indicator variable such that it is 1, if for each variable in the ith clause, it appears in at most a clauses. Let $B \in [1, \infty)$ denote a sufficiently large constant, which we will decide upon later.

For each variable x, the probability of it appearing in the i-th clause is $\frac{3}{n}$. Then we have

$$\mathbb{E}[\ \#\ \text{clauses that contain } x] = \sum_{i=1}^{m} \mathbb{E}[i\text{-th clause contains } x] = \frac{3m}{n}$$

By Markov's inequality,

$$\Pr[\ \#\ \text{clauses that contain } x \geq a] \leq \mathbb{E}[\ \#\ \text{clauses that contain } x]/B = \frac{3m}{Bn}$$

By a union bound, we can compute $\mathbb{E}[z_i]$,

$$\begin{aligned}\mathbb{E}[z_i] = &\Pr[z_i = 1] \\ &\geq 1 - 3\Pr[\text{ one variable in } i\text{-th clause appearing} \geq B \text{ clauses }] \\ &\geq 1 - \frac{9m}{Bn}.\end{aligned}$$

Furthermore, we have

$$\mathbb{E}[z] = \mathbb{E}[\sum_{i=1}^{m} z_i] = \sum_{i=1}^{m} \mathbb{E}[z_i] \geq (1 - \frac{9m}{Bn})m.$$

Note that $z \leq m$. Thus $\mathbb{E}[z] \leq m$. Let $b \in (0, 1)$ denote a sufficiently small constant. We can show

$$\begin{aligned}\Pr[m - z \geq bm] &\leq \frac{\mathbb{E}[m - z]}{bm} \\ &= \frac{m - \mathbb{E}[z]}{bm} \\ &\leq \frac{m - (1 - \frac{9m}{Bn})m}{bm} \\ &= \frac{9m}{Bbn}.\end{aligned}$$

This implies that with probability at least $1 - \frac{9m}{Bbn}$, we have $m - z \leq bm$. Notice that in random-ETH , $m = cn$ for a constant c. Thus, by choosing a sufficiently large constant B (which is a function of c, b), we can obtain arbitrarily large constant success probability. □

21.9.4.3 Reduction

We reduce 3SAT to tensor rank by following the same construction in [Hås90]. To obtain a stronger hardness result, we use the property that each variable only appears in at most B (some constant) clauses and that the cover number of an unsatisfiable 3SAT instance

is large. Note that both MAX-E3SAT(B) instances and random-ETH instances have that property. Also each MAX-E3SAT(B) is also a 3SAT instance. Thus if the reduction holds for 3SAT , it also holds for MAX-E3SAT(B) , and similarly for random-ETH .

Recall the definition of 3SAT : 3SAT is the problem of given a Boolean formula of n variables in CNF form with at most 3 variables in each of the m clauses, is it possible to find a satisfying assignment to the formula? We say $x_1, x_2, \cdots, x_n$ are variables and $x_1, \overline{x}_1, x_2, \overline{x}_2, \cdots, x_n, \overline{x}_n$ are literals. We transform this to the problem of computing the rank of a tensor of size $n_1 \times n_2 \times n_3$ where $n_1 = 2 + n + 2m$, $n_2 = 3n$ and $n_3 = 3n + m$. T has the following n_3 column-row faces, where each of the faces is an $m_1 \times n_2$ matrix,

- n variable matrices $V_i \in \mathbb{R}^{n_1 \times n_2}$. It has a 1 in positions $(1, 2i-1)$ and $(2, 2i)$ while all other elements are 0.
- n help matrices $S_i \in \mathbb{R}^{n_1 \times n_2}$. It has a 1 position in $(1, 2n+i)$ and is 0 otherwise.
- n help matrices $M_i \in \mathbb{R}^{n_1 \times n_2}$. It has a 1 in positions $(1, 2i-1), (2+i, 2i)$ and $(2+i, 2n+i)$ and is 0 otherwise.
- m clause matrices $C_l \in \mathbb{R}^{n_1 \times n_2}$. Suppose the clause c_l contains the literals $u_{l,1}, u_{l,2}$ and $u_{l,3}$. For each $j \in [3]$, $u_{l,j} \in \{x_1, x_2, \cdots, x_n, \overline{x}_1, \overline{x}_2, \cdots, \overline{x}_n\}$. Note that $x_i, \overline{x}_i$ are the literals of the 3SAT formula. We can also think of $x_i, \overline{x}_i$ as length $3n$ vectors. Let x_i denote the vector that has a 1 in position $2i-1$, i.e., $x_i = e_{2i-1}$. Let $\overline{x}_i$ denote the vector that has a 1 in positions $2i-1$ and $2i$, $\overline{x}_i = e_{2i-1} + e_{2i}$.
  - Row 1 is the vector $u_{l,1} \in \mathbb{R}^{3n}$,
  - Row $2 + n + 2l - 1$ is the vector $u_{l,1} - u_{l,2} \in \mathbb{R}^{3n}$,

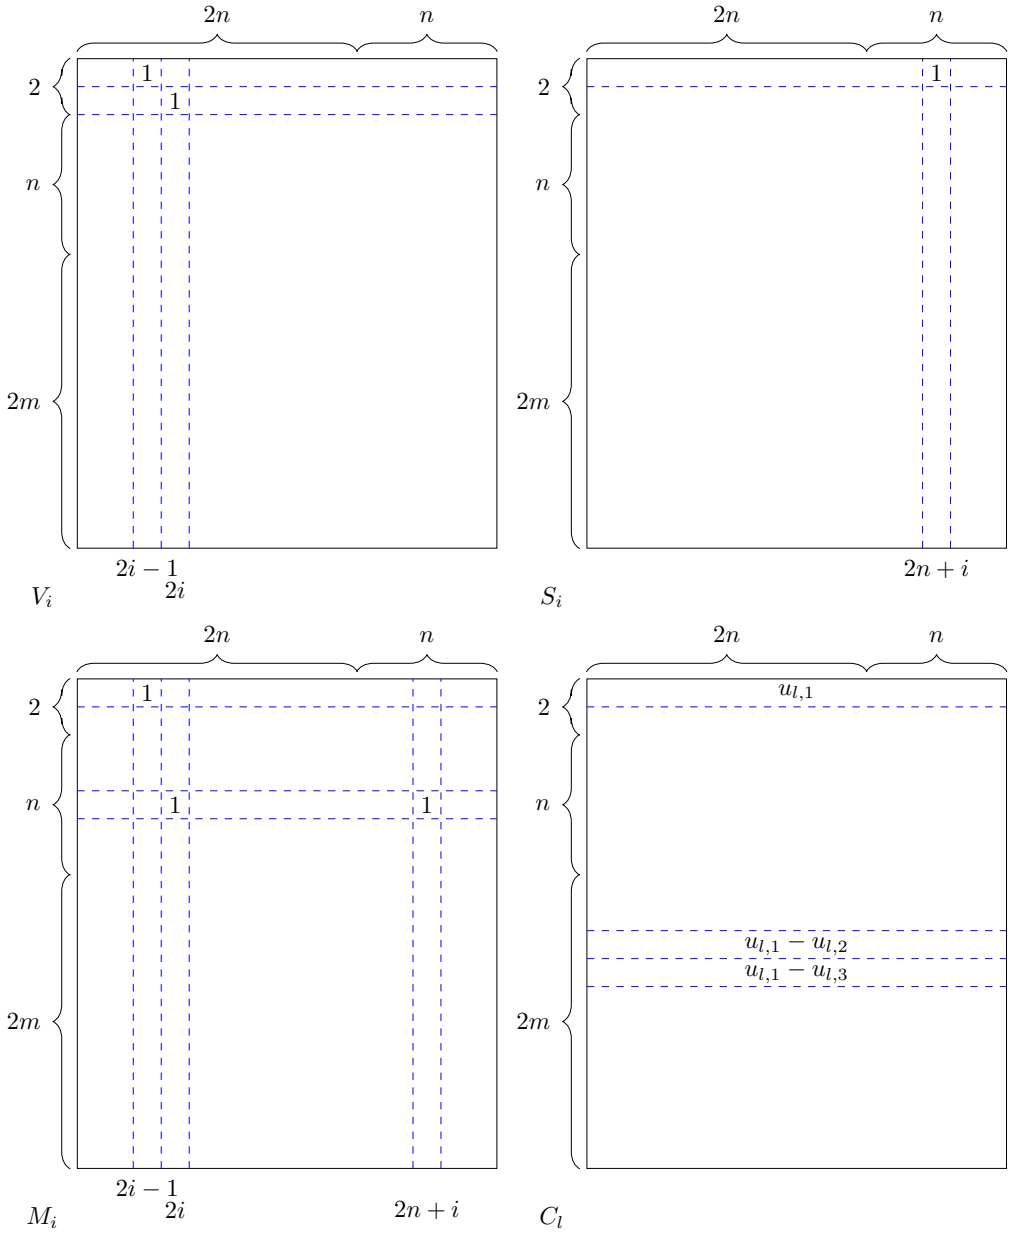

Figure 21.11: There are $3n + m$ column-row faces, $V_i, \forall i \in [n]$, $S_i, \forall i \in [n]$, $M_i, \forall i \in [n]$, $C_l, \forall l \in [m]$. In face C_l, each $u_{l,j}$ is either x_i or $\overline{x}_i$ where $x_i = e_{2i-1}$ and $\overline{x}_i = e_{2i-1} + e_{2i}$.

– Row $2 + n + 2l$ is the vector $u_{l,1} - u_{l,3} \in \mathbb{R}^{3n}$.

First, we can obtain Lemma 21.9.23 which follows by Lemma 2 in [Hås90]. For completeness, we provide a proof.

Lemma 21.9.23. *If the formula is satisfiable, then the constructed tensor has rank at most* $4n + 2m$.

Proof. We will construct $4n+2m$ rank-1 matrices $V_i^{(1)}, V_i^{(2)}, S_i^{(1)}, M_i^{(1)}, C_l^{(1)}$ and $C_l^{(2)}$. Then the goal is to show that for each matrix in the set

$$\{V_1, V_2, \cdots, V_n, S_1, S_2, \cdots, S_n, M_1, M_2, \cdots, M_n, C_1, C_2, \cdots, C_m\},$$

it can be written as a linear combination of these constructed matrices.

- Matrices $V_i^{(1)}$ and $V_i^{(2)}$. $V_i^{(1)}$ has the first row equal to x_i iff $\alpha_i = 1$ and otherwise $\overline{x}_i$. All the other rows are 0. We set $V_i^{(2)} = V_i - V_i^{(1)}$.
- Matrices $S_i^{(1)}$. $S_i^{(1)} = S_i$.
- Matrices $M_i^{(1)}$.

$$M_i^{(1)} = \begin{cases} M_i - V_i^{(1)} & \text{if } \alpha_i = 1 \\ M_i - V_i^{(1)} - S_i & \text{if } \alpha_i = 0 \end{cases}$$

- Matrices $C_l^{(1)}$ and $C_l^{(2)}$. Let $x_i = \alpha_i$ be the assignment that makes the clause c_l true. Then $C_l - V_i^{(1)}$ has rank 2, since either it has just two nonzero rows (in the case where x_i is the first variable in the clause) or it has three nonzero rows of which two are equal. In both cases we just need two additional rank 1 matrices.

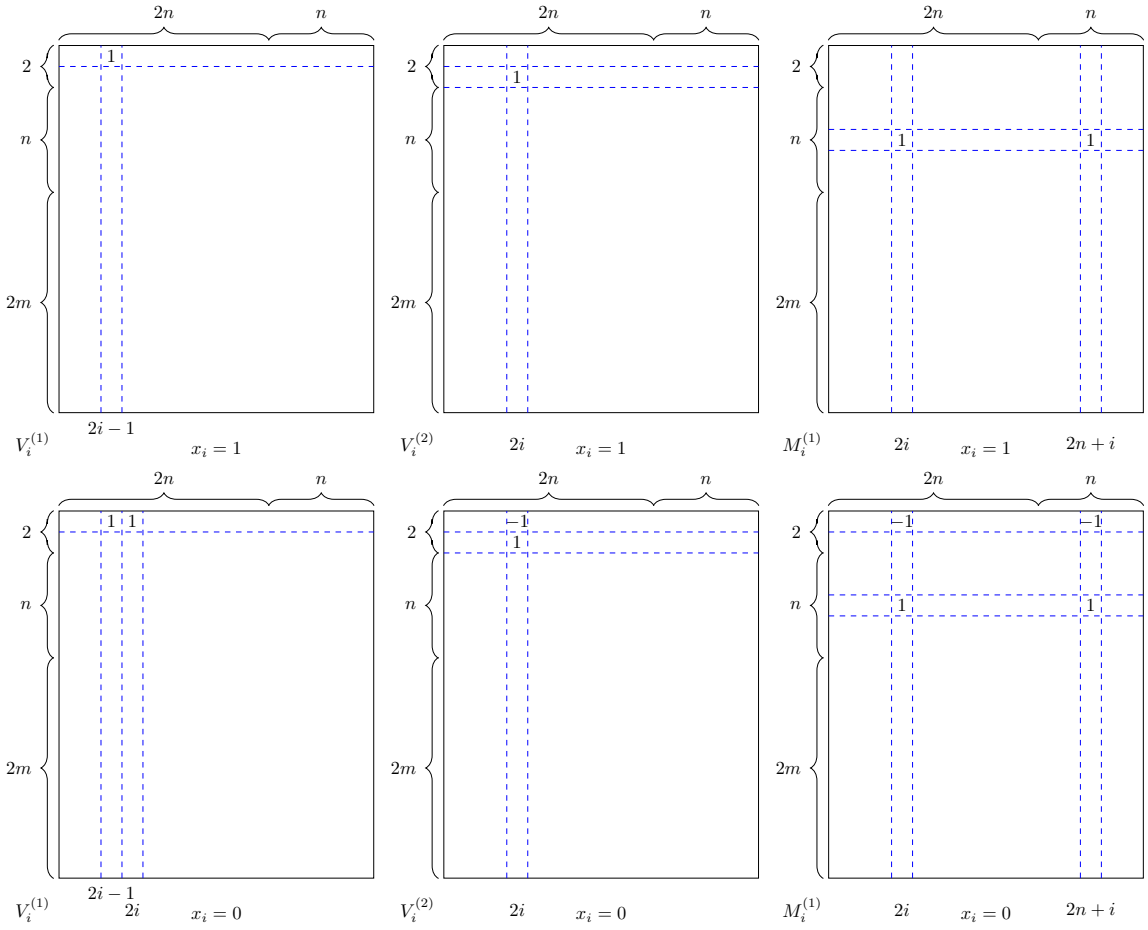

Figure 21.12: Two possibilities for $V_i^{(1)}, \forall i \in [n]$, $V^{(2)}, \forall i \in [n]$, $M_i^{(1)}, \forall i \in [n]$.

□

Once the 3SAT instance S is unsatisfiable, then its cover number is at least 1. For each unsatisfiable 3SAT instance S with cover number p, we can show that the constructed tensor has rank at most $4n + 2m + O(p)$ and also has rank at least $4n + 2m + \Omega(p)$. We first prove an upper bound,

Lemma 21.9.24. *For a* 3SAT *instance* S*, let* $y \in \{0, 1\}$ *denote a string such that* $S(y)$ *has*

a set L that contains unsatisfiable clauses. Let p denote the smallest number of variables that cover all clauses in L. Then the constructed tensor T has rank at most $4n + 2m + p$.

Proof. Let y denote a length-n Boolean string $(\alpha_1, \alpha_2, \cdots, \alpha_n)$. Based on the assignment y, all the clauses of S can be split into two sets: L contains all the unsatisfied clauses and $\overline{L}$ contains all the satisfied clauses. We use set P to denote a set of variables that covers all the clauses in set L. Let $p = |P|$. We will construct $4n + 2m + p$ rank-1 matrices $V_i^{(1)}, V_i^{(2)}$, $S_i^{(1)}$, $M_i^{(1)}$, $\forall i \in [n]$, $C_l^{(1)}$, $C_l^{(2)}$, $\forall l \in [m]$, and $V_j^{(3)}$, $\forall j \in P$. Then the goal is to show that the V_i, S_i, M_i and C_l can be written as linear combinations of these constructed matrices.

- Matrices $V_i^{(1)}$ and $V_i^{(2)}$. $V_i^{(1)}$ has first row equal to x_i iff $\alpha_i = 1$ and otherwise $\overline{x}_i$. All the other rows are 0. We set $V_i^{(2)} = V_i - V_i^{(1)}$.

- Matrices $V_j^{(3)}$. For each $j \in P$, $V_j^{(3)}$ has the first row equal to x_i iff $\alpha_i = 0$ and otherwise $\overline{x}_i$.

- Matrices $S_i^{(1)}$. $S_i^{(1)} = S_i$.

- Matrices $M_i^{(1)}$.

$$M_i^{(1)} = \begin{cases} M_i - V_i^{(1)} & \text{if } \alpha_i = 1 \\ M_i - V_i^{(1)} - S_i & \text{if } \alpha_i = 0 \end{cases}$$

- Matrices $C_l^{(1)}$ and $C_l^{(2)}$.

  - For each $l \notin L$, clause c_l is satisfied according to assignment y. Let $x_i = \alpha_i$ be the assignment that makes the clause c_l true. Then $C_l - V_i^{(1)}$ has rank 2, since either it has just two nonzero rows (in the case where x_i is the first variables in

the clause) or it has three nonzero rows of which two are equal. In both cases we just need two additional rank 1 matrices.

– For each $l \in L$. It means clause c_l is unsatisfied according to assignment y. Let $x_{j_1} = \alpha_{j_1}, x_{j_2} = \alpha_{j_2}, x_{j_3} = \alpha_{j_3}$ be an assignment that makes the clause c_l false. In other words, one of j_1, j_2, j_3 must be P according to the definition that P covers L. Then matrix $C_l - V_{j_1}^{(3)}$ has rank 2, since either it has just two nonzero rows (in the case where x_{j_1} is the first variables in the clause) or it has three nonzero rows of which two are equal. In both cases we just need two additional rank 1 matrices.

We finish the proof by taking the P that has the smallest size. □

Further, we have:

Corollary 21.9.25. *For a* 3SAT *instance S, let p denote the cover number of S, then the constructed tensor T has rank at most $4n + 2m + p$.*

Proof. This follows by applying Lemma 21.9.24 to all the input strings and the definition of cover number (Definition 21.9.7). □

We can split the tensor $T \in \mathbb{R}^{(2+n+3m)\times 3n\times(3n+m)}$ into two sub-tensors, one is $T_1 \in \mathbb{R}^{2\times 3n\times(3n+m)}$ (that contains the first two row-tube faces of T and linear combination of the remaining $2m$ row-tube faces of T), and the other is $T_2 \in \mathbb{R}^{(n+2m)\times 3n\times(3n+m)}$ (that contains the next $n + 2m$ row-tube faces of T). We first analyze the rank of T_1 and then analyze the rank of T_2.

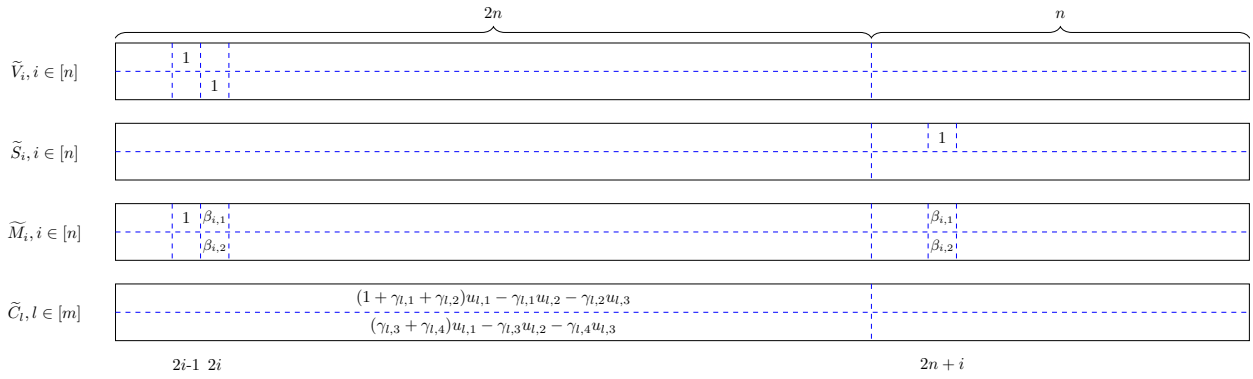

Figure 21.13: $\widetilde{V}_i$,$\widetilde{S}_i$,$\widetilde{M}_i$,$\widetilde{C}_l$.

Claim 21.9.26. *The rank of T_2 is $n + 2m$.*

Proof. According to Figure 21.11, the nonzero rows are distributed in $n + m$ fully separated sub-tensors. It is obvious that the rank of each one of those n sub-tensors is 1, and the rank of each of those m sub-tensors is 2. Thus, overall, the rank T_2 is $n + 2m$. □

To make sure $\text{rank}(T) = \text{rank}(T_1) + \text{rank}(T_2)$, the $T_1 \in \mathbb{R}^{2\times 3n\times(3n+m)}$ can be described as the following $3n + m$ column-row faces, and each of the faces is a $2 \times 3n$ matrix.

- Matrices $\widetilde{V}_i, \forall i \in [n]$. The two rows are from the first two rows of V_i in Figure 21.11, i.e., the first row is e_{2i-1} and the second row is e_{2i}.
- Matrices $\widetilde{S}_i, \forall i \in [n]$. The two rows are from the first two rows of S_i in Figure 21.11, i.e., the first row is e_{2n+i} and the second row is zero everywhere else.
- Matrices $\widetilde{M}_i, \forall i \in [n]$. The first row is $e_{2i-1} + \beta_{i,1}(e_{2i} + e_{2n+i})$, while the second row is $\beta_{i,2}(e_{2i} + e_{2n+i})$.

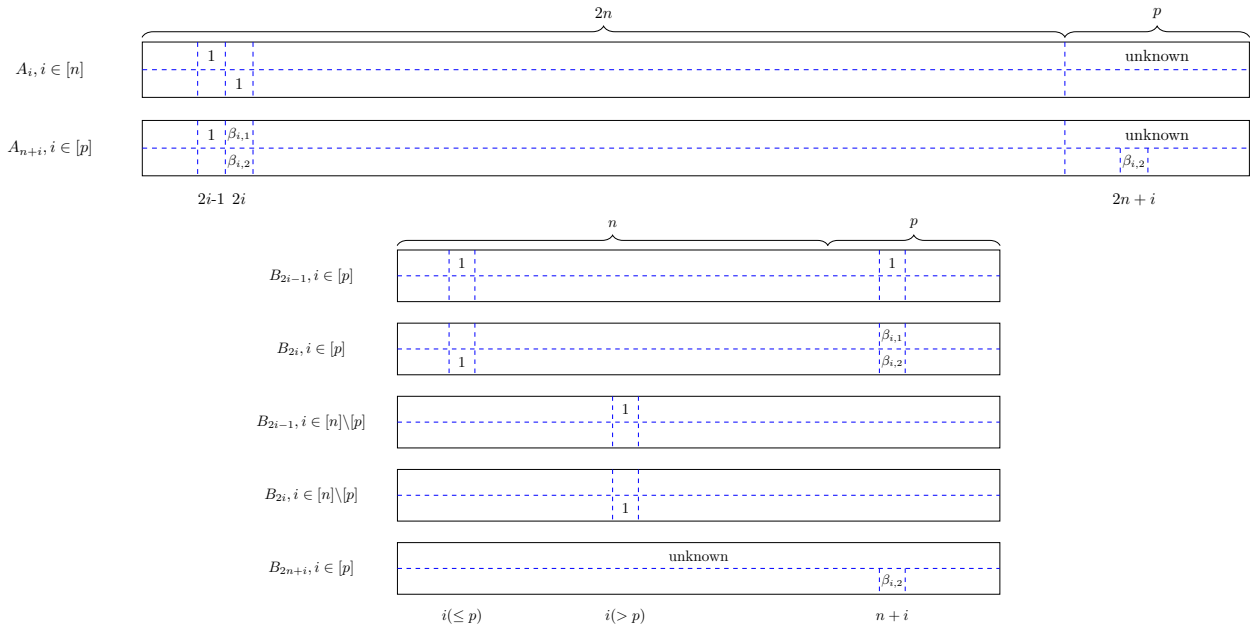

Figure 21.14: There are $n+p$ matrices $A_i \in \mathbb{R}^{2\times(2n+p)}, \forall i \in [n+p]$ and $2n+p$ matrices $B_i \in \mathbb{R}^{2\times(n+p)}, \forall i \in [2n+p]$. Tensor A and tensor B represet the same tensor, and for each $i \in [n+p], j \in [2], l \in [2n+p]$, $(A_i)_{j,l} = (B_l)_{j,i}$.

- Matrices $\widetilde{C}_l, \forall i \in [m]$. The first row is $(1+\gamma_{l,1}+\gamma_{l,2})u_{l,1} - \gamma_{l,1}u_{l,2} - \gamma_{l,2}u_{l,3}$ and the second is $(\gamma_{l,3}+\gamma_{l,4})u_{l,1} - \gamma_{l,3}u_{l,2} - \gamma_{l,4}u_{l,3}$,

where for each $i \in [3n]$, we use vector e_i to denote a length $3n$ vector such that it only has a 1 in position i and 0 otherwise. β, γ are variables. The goal is to show a lower bound for,

$$\operatorname*{rank}_{\beta,\gamma}(T_1).$$

Lemma 21.9.27. *Let P denote the set $\{i \mid$ the second row of matrix $\widetilde{M_i}$ is nonzero, $\forall i \in [n]\}$. Then the rank of T_1 is at least $3n + |P|$.*

Proof. We define $p = |P|$. Without loss of generality, we assume that for each $i \in [p]$, the second row of matrix $\widetilde{M_i}$ is nonzero.

Notice that matrices $\widetilde{V}_i$, $\widetilde{S}_i$, $\widetilde{M}_i$ have size $2 \times 3n$, but we only focus on the first $2n+p$ columns. Thus, we have $n+p$ column-row faces (from the 3rd dimension) $A_j \in \mathbb{R}^{2\times(2n+p)}$,

- A_j, $1 \le j \le n$, A_j is the first $2n+p$ columns of $\widetilde{V}_j - \sum_{i=1}^{n} \alpha_{i,j}\widetilde{S}_i \in \mathbb{R}^{2\times 3n}$, where $\alpha_{i,j}$ are some coefficients.
- A_{n+j}, $1 \le j \le p$, A_j is the first $2n+p$ columns of $\widetilde{M}_j - \sum_{i=1}^{n} \alpha_{i,n+j}\widetilde{S}_i \in \mathbb{R}^{2\times 3n}$, where $\alpha_{i,j}$ are some coefficients.

Consider the first $2n+p$ column-tube faces (from 2nd dimension), B_j, $\forall j \in [2n+p]$, of T_1. Notice that these matrices have size $2 \times (n+p)$.

- B_{2i-1}, $1 \le i \le p$, it has a 1 in positions $(1,i)$ and $(1,n+i)$.
- B_{2i}, $1 \le i \le p$, it has $\beta_{i,1}$ in position $(1,n+i)$, 1 in position $(2,i)$ and $\beta_{i,2}$ in position $(2,n+i)$.
- B_{2i-1}, $p+1 \le i \le n$, it has 1 in position $(1,i)$.
- B_{2i}, $p+1 \le i \le n$, it has 1 in position $(2,i)$.
- B_{2n+i}, $1 \le i \le p$, the first row is unknown, the second row has $\beta_{i,2}$ in position in $(2,n+i)$.

It is obvious that the first $2n$ matrices are linearly independent, thus the rank is at least $2n$. We choose the first $2n$ matrices as our basis. For B_{2n+1}, we try to write it as a linear combination of the first $2n$ matrices $\{B_i\}_{i\in[2n]}$. Consider the second row of B_{2n+1}. The first n positions are all 0. The matrices B_{2i} all have disjoint support for the second row of the

first n columns. Thus, the matrices B_{2i} should not be used. Consider the second row of $B_{2i-1}, \forall i \in [n]$. None of them has a nonzero value in position $n+1$. Thus B_{2n+1} cannot be written as a linear combination of of the first $2n$ matrices. Thus, we can show for any $i \in [p]$, B_{2n+i} cannot be written as a linear combination of matrices $\{B_i\}_{i\in[2n]}$. Consider the p matrices $\{B_{2n+i}\}_{i\in[p]}$. Each of them has a different nonzero position in the second row. Thus these matrices are all linearly independent. Putting it all together, we know that the rank of matrices $\{B_i\}_{i\in[2n+p]}$ is at least $2n+p$. □

Next, we consider another special case when $\beta_{i,2} = 0$, for all $i \in [n]$. If we subtract $\beta_{i,1}$ times $\widetilde{S}_i$ from $\widetilde{M}_i$ and leave the other column-row faces (from the 3rd dimension) as they are, and we make all column-tube faces(from the 2nd dimension) for $j > 2n$ identically 0, then all other choices do not change the first $2n$ column-tube faces (from the 2nd dimension) and make some other column-tube faces (from the 2nd dimension) nonzero. Such a choice could clearly only increase the rank of T. Thus, we obtain,

$$\operatorname{rank}(T) = 2n + 2m + \min \operatorname{rank}(T_3),$$

where T_3 is a tensor of size $2 \times 2n \times (2n+m)$ given by the following column-row faces (from 3rd dimension) $A_i, \forall i \in [2n+m]$ and each matrix has size $2 \times 2n$ (shown in Figure 21.15).

- A_i, $i \in [n]$, the first $2n$ columns of $\widetilde{V}_i$.
- A_{n+i}, $i \in [n]$, the first $2n$ columns of $\widetilde{M}_i$. The first row is $e_{2i-1} + \beta_{i,1} e_{2i}$, and the second row is 0.
- A_{2n+l}, $l \in [m]$, the first $2n$ columns of $\widetilde{C}_l$. The first row is $(1+\gamma_{l,1}+\gamma_{l,2})u_{l,1} - \gamma_{l,1}u_{l,2} - \gamma_{l,2}u_{l,3}$, and the second row is $(\gamma_{l,3}+\gamma_{l,4})u_{l,1} - \gamma_{l,3}u_{l,2} - \gamma_{l,4}u_{l,3}$.

We can show

Lemma 21.9.28. *Let p denote the cover number of the* 3SAT *instance. T_3 has rank at least $2n + \Omega(p)$.*

Proof. First, we can show that all matrices $A_{n+i} - A_i$ and A_{n+i} (for all $i \in [n]$) are in the expansion of tensor T_3. Thus, the rank of T_3 is at least $2n$.

We need the following claim:

Claim 21.9.29. *For any $l \in [m]$, if A_{2n+l} can be written as a linear combination of $\{A_{n+i} - A_i\}_{i\in[n]}$ and $\{A_{n+i}\}_{i\in[n]}$, then the second row of A_{2n+l} is 0, and the first row of one of the A_{n+i} is u_i where u_i is one of the literals appearing in clause c_l.*

Proof. We prove this for the second row first. For each $l \in [m]$, we consider the possibility of using all matrices $A_{n+i} - A_i$ and A_{n+i} to express matrix A_{2n+l}. If the second row of A_{2n+l} is nonzero, then it must have a nonzero entry in an odd position. But there is no nonzero in an odd position of the second row of any of matrices $A_{n+i} - A_i$ and A_{n+i}.

For the first row. It is obvious that the first row of A_{2n+l} must have at least one nonzero position, for any $\gamma_{l,1}, \gamma_{l,2}$. Let u_j be a literal belonging to the variable x_i which appears in the first row of A_{2n+l} with a nonzero coefficient. Since only A_{n+i} of all the other $A_{n+s}, \forall s \in [n]$ matrices has nonzero elements in either of the positions $(1, 2i-1)$ or $(1, 2i)$, then A_{n+i} must be used to cancel these elements. Thus, the first row of A_{n+i} must be a multiple of u_j and since the element in position $(1, 2i-1)$ of A_{n+i} is 1, this multiple must be 1.

□

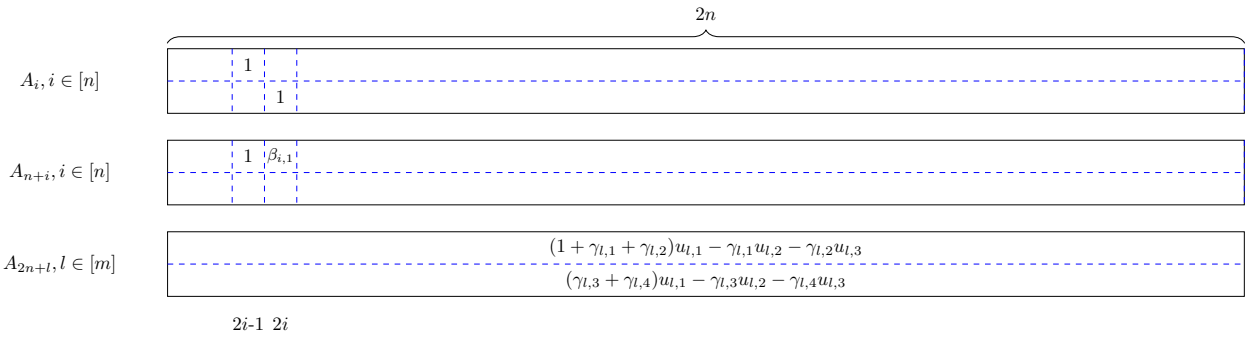

Figure 21.15: For any $i \in [n]$, $\beta_{i,1} \in \mathbb{R}$, for any $l \in [m]$, $\gamma_{l,1}, \gamma_{l,2} \in \mathbb{R}$, for any $l \in [m]$, if the first literal of clause l is x_j, then row vector $u_{l,1} = e_{2i-1} \in \mathbb{R}^{2n}$; if the first literal of clause l is $\overline{x}_j$, then row vector $u_{l,1} = e_{2i-1} + e_{2i} \in \mathbb{R}^{2n}$.

Note that matrices $A_i, \forall i \in [n]$ have the property that, for any matrix in $\{A_{n+1}, \cdots, A_{2n+m}\}$, it cannot be written as the linear combination of matrices $A_i, \forall i \in [n]$. Let $\widetilde{A} \in \mathbb{R}^{(n+m)\times 2n}$ denote a matrix that consists of the first rows of $\{A_{n+1}, \cdots, A_{2n+m}\}$. According to the property of matrices $A_i, \forall i \in [n]$, and that the rank of a tensor is always greater than or equal to the rank of any sub-tensor, we know that

$$\operatorname{rank}(T_3) \geq n + \min \operatorname{rank}(\widetilde{A}).$$

Claim 21.9.30. *For a* 3SAT *instance S, for any input string $y \in \{0,1\}^n$, set $\beta_{*,1}$ to be the entry-wise flipping of y,* (I) *if the clause l is satisfied, then the $(n+l)$-th row of $\widetilde{A} \in \mathbb{R}^{(n+m)\times 2n}$ can be written as a linear combination of the first n rows of $\widetilde{A}$.* (II) *if the clause l is unsatisfied, then the $(n+l)$-th row of $\widetilde{A}$ cannot be written as a linear combination of the first n rows of $\widetilde{A}$.*

Proof. Part (I), consider a clause l which is satisfied with input string y. Then there must exist a variable x_i belonging to clause l (either literal x_i or literal $\overline{x}_i$) and one of the following

holds: if x_i belongs to clause l, then $\alpha_i = 1$; if $\overline{x}_i$ belongs to clause l, then $\alpha_i = 0$. Suppose clause l contains literal x_i. The other case can be proved in a similar way. We consider the $(n+l)$-th row. One of the following assignments $(0,0), (-1,0), (0,-1)$ to $\gamma_{l,1}, \gamma_{l,1}$ is going to set the $(n+l)$-th row of $\widetilde{A}$ to be vector e_{2i-1}. We consider the i-th row of $\widetilde{A}$. Since we set $\alpha_i = 1$, then we set $\beta_{i,1} = 0$, it follows that the i-th row of A becomes e_{2i-1}. Therefore, the $(n+l)$-th row of $\widetilde{A}$ can be written as a linear combination of $\widetilde{A}$.

Part (II), consider a clause l which is unsatisfied with input string y. Suppose that clause contains three literals $x_{i_1}, x_{i_2}, x_{i_3}$ (the other seven possibilities can be proved in a similar way). Then for input string y, we have $\alpha_{i_1} = 0$, $\alpha_{i_2} = 0$ and $\alpha_{i_3} = 0$, otherwise this clause l is satisfied. Consider i_1-th row of $\widetilde{A}$. It becomes $e_{2i_1-1} + e_{2i_1}$. Similarly for the i_2-th row and i_3-th row. Consider the $(n+l)$-th row. We can observe that all of positions $2i_1, 2i_2, 2i_3$ must be 0. Any linear combination formed by the i_1, i_2, i_3-th row of $\widetilde{A}$ must have one nonzero in one of positions $2i_1, 2i_2, 2i_3$. However, if we consider the $(n+l)$-th row of $\widetilde{A}$, one of the positions $2i_1, 2i_2, 2i_3$ must be 0. Also, the remaining $n-3$ of the first n rows of $\widetilde{A}$ also have 0 in positions $2i_1, 2i_2, 2i_3$. Thus, we can show that the $(n+l)$-th row of $\widetilde{A}$ cannot be written as a linear combination of the first n rows. Similarly, for the other seven cases. □

Note that in order to make sure as many as possible rows in $n+1, \cdots, n+m$ can be written as linear combinations of the first n rows of $\widetilde{A}$, the $\beta_{i,1}$ should be set to either 0 or 1. Also each possibility of input string y is corresponding to a choice of $\beta_{i,1}$. According to the above Claim 21.9.30, let l_0 denote the smallest number of unsatisfied clauses over the choices of all the 2^n input strings. Then over all choices of β, γ, there must exist at least l_0 rows of

$\widetilde{A}_{n+1}, \cdots \widetilde{A}_{n+m}$, such that each of those rows cannot be written as the linear combination of the first n rows.

Claim 21.9.31. *Let $\widetilde{A} \in \mathbb{R}^{(n+m)\times 2n}$ denote a matrix that consists of the first rows of $A_{n+i}, \forall i \in [n]$ and $A_{n+l}, \forall l \in [m]$. Let p denote the cover number of* 3SAT *instance. Then* $\min \operatorname{rank}(\widetilde{A}) \geq n + \Omega(p)$.

Proof. For any choices of $\{\beta_{i,1}\}_{i\in[n]}$, there must exist a set of rows out of the next m rows such that, each of those rows cannot be written as a linear combination of the first n rows. Let L denote the set of those rows. Let t denote the maximum size set of disjoint rows from L. Since those t rows in L all have disjoint support, they are always linearly independent. Thus the rank is at least $n + t$.

Note that each row corresponds to a unique clause and each clause corresponds to a unique row. We can just pick an arbitrary clause l in L, then remove the clauses that are using the same literal as clause l from L. Because each variable occurs in at most B clauses, we only need to remove at most $3B$ clauses from L. We repeat the procedure until there is no clause L. The corresponding rows of all the clauses we picked have disjoint supports, thus we can show a lower bound for t,

$$t \geq |L|/(3B) \geq l_0/(3B) \geq p/(9B) \gtrsim p,$$

where the second step follows by $|L| \geq l_0$, the third step follows $3l_0 \geq p$, and the last step follows by B is some constant. □

Thus, putting it all together, we complete the proof.

□

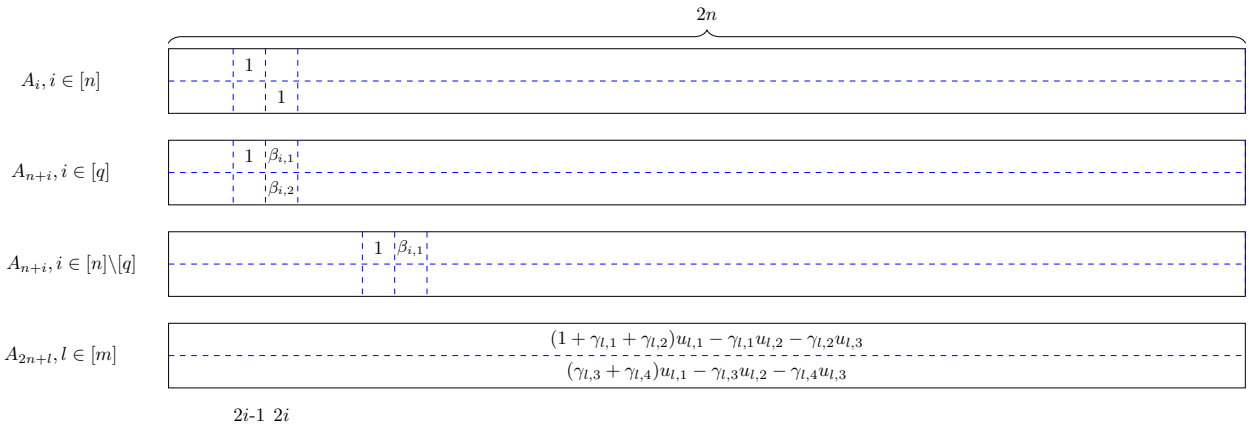

Figure 21.16: For any $i \in [n]$, $\beta_{i,1} \in \mathbb{R}$. For any $i \in [q]$, $\beta_{i,2} \in \mathbb{R}$. For any $l \in [m]$, $\gamma_{l,1}, \gamma_{l,2} \in \mathbb{R}$. For any $l \in [m]$, if the first literal of clause l is x_j, then row vector $u_{l,1} = e_{2i-1} \in \mathbb{R}^{2n}$; if the first literal of clause l is $\overline{x}_j$, then row vector $u_{l,1} = e_{2i-1} + e_{2i} \in \mathbb{R}^{2n}$.

Now, we consider a general case when there are q different $i \in [n]$ satisfying that $\beta_{i,2} \neq 0$. Similar to tensor T_3, we can obtain T_4 such that,

$$\operatorname{rank}(T) = 2n + 2m + \min \operatorname{rank}(T_4)$$

where T_4 is a tensor of size $2 \times 2n \times (2n+m)$ given by the following column-row faces (from 3rd dimension) A_i, $\forall i \in [2n+m]$ and each matrix has size $2 \times 2n$ (shown in Figure 21.16).

- A_i, $i \in [n]$, the first $2n$ columns of $\widetilde{V}_i$.
- A_{n+i}, $i \in [q]$, the first $2n$ columns of $\widetilde{M}_i$. The first row is $e_{2i-1} + \beta_{i,1} e_{2i}$, and the second row is $\beta_{i,2} e_{2i}$.
- A_{n+i}, $i \in \{q+1, \cdots, n\}$, the first $2n$ columns of $\widetilde{M}_i$. The first row is $e_{2i-1} + \beta_{i,1} e_{2i}$, and the second row is 0.

- A_{2n+l}, $l \in [m]$, the first $2n$ columns of $\widetilde{C}_l$. The first row is $(1+\gamma_{l,1}+\gamma_{l,2})u_{l,1} - \gamma_{l,1}u_{l,2} - \gamma_{l,2}u_{l,3}$, and the second row is $(\gamma_{l,3}+\gamma_{l,4})u_{l,1} - \gamma_{l,3}u_{l,2} - \gamma_{l,4}u_{l,3}$.

Note that modifying q entries(from Figure 21.15 to Figure 21.16) of a tensor can only decrease the rank by q, thus we obtain

Lemma 21.9.32. *Let q denote the number of i such that $\beta_{i,2} \neq 0$, and let p denote the cover number of the* 3SAT *instance. Then T_4 has rank at least $2n + \Omega(p) - q$.*

Combining the two perspectives we have

Lemma 21.9.33. *Let p denote the cover number of an unsatisfiable* 3SAT *instance. Then the tensor has rank at least $4n + 2m + \Omega(p)$.*

Proof. Let q denote the q in Figure 21.16. From one perspective, we know that the tensor has rank at least $4n + 2m + \Omega(p) - q$. From another perspective, we know that the tensor has rank at least $4n + 2m + q$. Combining them together, we obtain the rank is at least $4n + 2m + \Omega(p)/2$, which is still $4n + 2m + \Omega(p)$. □

Theorem 21.9.34. *Unless* ETH *fails, there is a $\delta > 0$ and an absolute constant $c_0 > 1$ such that the following holds. For the problem of deciding if the rank of a q-th order tensor, $q \geq 3$, with each dimension n, is at most k or at least $c_0 k$, there is no $2^{\delta k^{1-o(1)}}$ time algorithm.*

Proof. The reduction can be split into three parts.[13] The first part reduces the MAX-3SAT problem to the MAX-E3SAT problem by [MR10]. For each MAX-3SAT instance with

[13]The first two parts are accomplished by personal communication with Dana Moshkovitz and Govind Ramnarayan.

size n, the corresponding MAX-E3SAT instance has size $n^{1+o(1)}$. The second part is by reducing the MAX-E3SAT problem to MAX-E3SAT(B) by [Tre01]. For each MAX-E3SAT instance with size n, the corresponding MAX-E3SAT(B) instance has size $\Theta(n)$ when B is a constant. The third part is by reducing the MAX-E3SAT(B) problem to the tensor problem. Combining Theorem 21.9.5, Lemma 21.9.18 with this reduction, we complete the proof. □

Theorem 21.9.35. *Unless random-*ETH *fails, there is an absolute constant $c_0 > 1$ for which any deterministic algorithm for deciding if the rank of a q-th order tensor is at most k or at least $c_0 k$, requires $2^{\Omega(k)}$ time.*

Proof. This follows by combining the reduction with random-ETH and Lemma 21.9.22. □

Note that, if **BPP** = **P** then it also holds for randomized algorithms which succeed with probability 2/3.

Indeed, we know that any deterministic algorithm requires $2^{\Omega(n)}$ running time on tensors that have size $n \times n \times n$. Let $g(n)$ denote a fixed function of n, and $g(n) = o(n)$. We change the original tensor from size $n \times n \times n$ to $2^{g(n)} \times 2^{g(n)} \times 2^{g(n)}$ by adding zero entries. Then the number of entries in the new tensor is $2^{3g(n)}$ and the deterministic algorithm still requires $2^{\Omega(n)}$ running time on this new tensor. Assume there is a randomized algorithm that runs in $2^{cg(n)}$ time, for some constant $c > 3$. Then considering the size of this new tensor, the deterministic algorithm is a super-polynomial time algorithm, but the randomized algorithm is a polynomial time algorithm. Thus, by assuming **BPP** = **P**, we can rule out randomized algorithms, which means Theorem 21.9.35 also holds for randomized algorithms which succeed with probability 2/3.

We provide some some motivation for the $\mathbf{BPP} = \mathbf{P}$ assumption: this is a standard conjecture in complexity theory, as it is implied by the existence of strong pseudorandom generators or if any problem in deterministic exponential time has exponential size circuits [IW97].

21.10 Extension to Other Tensor Ranks

The tensor rank studied in the previous sections is also called the CP rank or canonical rank. The tensor rank can be thought of as a direct extension of the matrix rank. We would like to point out that there are other definitions of tensor rank, e.g., the tucker rank and train rank. In this section we explain how to extend our proofs to other notions of tensor rank. Section 21.10.1 provides the extension to tucker rank, and Section 21.10.2 provides the extension to train rank.

21.10.1 Tensor Tucker rank

Tensor Tucker rank has been studied in a number of works [KC07, PC08, MH09, ZW13, YC14]. We provide the formal definition here:

21.10.1.1 Definitions

Definition 21.10.1 (Tucker rank)**.** Given a third order tensor $A \in \mathbb{R}^{n \times n \times n}$, we say A has tucker rank k if k is the smallest integer such that there exist three matrices $U, V, W \in \mathbb{R}^{n \times k}$ and a (small) tensor $C \in \mathbb{R}^{k \times k \times k}$ satisfying

$$A_{i,j,l} = \sum_{i'=1}^{k} \sum_{j'=1}^{k} \sum_{l'=1}^{k} C_{i',j',l'} U_{i,i'} V_{j,j'} W_{l,l'}, \forall i, j, l \in [n] \times [n] \times [n],$$

or equivalently,

$$A = C(U, V, W).$$

21.10.1.2 Algorithm

Theorem 21.10.1. *Given a third order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$ and $\epsilon \in (0, 1)$, there exists an algorithm which takes $O(\mathrm{nnz}(A)) + n \,\mathrm{poly}(k, 1/\epsilon) + 2^{O(k^2/\epsilon + k^3)}$ time and outputs three matrices $U, V, W \in \mathbb{R}^{n \times k}$, and a tensor $C \in \mathbb{R}^{k \times k \times k}$ for which*

$$\|C(U, V, W) - A\|_F^2 \leq (1 + \epsilon) \min_{\text{tucker rank} - k \ A_k} \|A_k - A\|_F^2$$

holds with probability $9/10$.

Proof. We define OPT to be

$$\mathrm{OPT} = \min_{\text{tucker rank} - k \ A'} \|A' - A\|_F^2.$$

  return C,$A_1 S_1 X_1$, $A_2 S_2 X_2$, and $A_3 S_3 X_3$.
end procedure

Suppose the optimal $A_k = C^*(U^*, V^*, W^*)$. We fix $C^* \in \mathbb{R}^{k \times k \times k}$, $V^* \in \mathbb{R}^{n \times k}$ and $W^* \in \mathbb{R}^{n \times k}$. We use $V_1^*, V_2^*, \cdots, V_k^*$ to denote the columns of V^* and $W_1^*, W_2^*, \cdots, W_k^*$ to denote the columns of W^*.

We consider the following optimization problem,

$$\min_{U_1, \cdots, U_k \in \mathbb{R}^n} \|C^*(U, V^*, W^*) - A\|_F^2,$$

which is equivalent to

$$\min_{U_1, \cdots, U_k \in \mathbb{R}^n} \|U \cdot C^*(I, V^*, W^*) - A\|_F^2,$$

because $C^*(U, V^*, W^*) = U \cdot C^*(I, V^*, W^*)$ according to Definition 21.2.6.

Recall that $C^*(I, V^*, W^*)$ denotes a $k \times n \times n$ tensor. Let $(C^*(I, V^*, W^*))_1$ denote the matrix obtained by flattening $C^*(I, V^*, W^*)$ along the first dimension. We use matrix Z_1

to denote $(C^*(I, V^*, W^*))_1 \in \mathbb{R}^{k \times n^2}$. Then we can obtain the following equivalent objective function,

$$\min_{U \in \mathbb{R}^{n \times k}} \|UZ_1 - A_1\|_F^2.$$

Notice that $\min_{U \in \mathbb{R}^{n \times k}} \|UZ_1 - A_1\|_F^2 = \mathrm{OPT}$, since $A_k = U^* Z_1$.

Let $S_1^\top \in \mathbb{R}^{s_1 \times n^2}$ be the sketching matrix defined in Definition 21.3.12, where $s_1 = O(k/\epsilon)$. We obtain the following optimization problem,

$$\min_{U \in \mathbb{R}^{n \times k}} \|UZ_1 S_1 - A_1 S_1\|_F^2.$$

Let $\widehat{U} \in \mathbb{R}^{n \times k}$ denote the optimal solution to the above optimization problem. Then $\widehat{U} = A_1 S_1 (Z_1 S_1)^\dagger$. By Lemma 21.3.10 and Theorem 21.3.11, we have

$$\|\widehat{U} Z_1 - A_1\|_F^2 \leq (1+\epsilon) \min_{U \in \mathbb{R}^{n \times k}} \|UZ_1 - A_1\|_F^2 = (1+\epsilon)\,\mathrm{OPT},$$

which implies

$$\left\| C^*(\widehat{U}, V^*, W^*) - A \right\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}\,.$$

To write down $\widehat{U}_1, \cdots, \widehat{U}_k$, we use the given matrix A_1, and we create $s_1 \times k$ variables for matrix $(Z_1 S_1)^\dagger$.

As our second step, we fix $\widehat{U} \in \mathbb{R}^{n \times k}$ and $W^* \in \mathbb{R}^{n \times k}$, and we convert tensor A into matrix A_2. Let matrix Z_2 denote $(C^*(\widehat{U}, I, W^*))_2 \in \mathbb{R}^{k \times n^2}$. We consider the following objective function,

$$\min_{V \in \mathbb{R}^{n \times k}} \|VZ_2 - A_2\|_F^2,$$

for which the optimal cost is at most $(1+\epsilon)\,\mathrm{OPT}$.

Let $S_2^\top \in \mathbb{R}^{s_2 \times n^2}$ be a sketching matrix defined in Definition 21.3.12, where $s_2 = O(k/\epsilon)$. We sketch S_2 on the right of the objective function to obtain a new objective function,

$$\min_{V \in \mathbb{R}^{n \times k}} \|V Z_2 S_2 - A_2 S_2\|_F^2.$$

Let $\widehat{V} \in \mathbb{R}^{n \times k}$ denote the optimal solution to the above problem. Then $\widehat{V} = A_2 S_2 (Z_2 S_2)^\dagger$. By Lemma 21.3.10 and Theorem 21.3.11, we have,

$$\|\widehat{V} Z_2 - A_2\|_F^2 \leq (1+\epsilon) \min_{V \in \mathbb{R}^{n \times k}} \|V Z_2 - A_2\|_F^2 \leq (1+\epsilon)^2\,\mathrm{OPT},$$

which implies

$$\left\| C^*(\widehat{U}, \widehat{V}, W^*) - A \right\|_F^2 \leq (1+\epsilon)^2\,\mathrm{OPT}\,.$$

To write down $\widehat{V}_1, \cdots, \widehat{V}_k$, we need to use the given matrix $A_2 \in \mathbb{R}^{n^2 \times n}$, and we need to create $s_2 \times k$ variables for matrix $(Z_2 S_2)^\dagger$.

As our third step, we fix the matrices $\widehat{U} \in \mathbb{R}^{n \times k}$ and $\widehat{V} \in \mathbb{R}^{n \times k}$. We convert tensor $A \in \mathbb{R}^{n \times n \times n}$ into matrix $A_3 \in \mathbb{R}^{n^2 \times n}$. Let matrix Z_3 denote $(C^*(\widehat{U}, \widehat{V}, I))_3 \in \mathbb{R}^{k \times n^2}$. We consider the following objective function,

$$\min_{W \in \mathbb{R}^{n \times k}} \|W Z_3 - A_3\|_F^2,$$

which has optimal cost at most $(1+\epsilon)^2\,\mathrm{OPT}$.

Let $S_3^\top \in \mathbb{R}^{s_3 \times n^2}$ be a sketching matrix defined in Definition 21.3.12, where $s_3 = O(k/\epsilon)$. We sketch S_3 on the right of the objective function to obtain a new objective

function,

$$\min_{W \in \mathbb{R}^{n \times k}} \|W Z_3 S_3 - A_3 S_3\|_F^2.$$

Let $\widehat{W} \in \mathbb{R}^{n \times k}$ denote the optimal solution of the above problem. Then $\widehat{W} = A_3 S_3 (Z_3 S_3)^\dagger$. By Lemma 21.3.10 and Theorem 21.3.11, we have,

$$\|\widehat{W} Z_3 - A_3\|_F^2 \leq (1+\epsilon) \min_{W \in \mathbb{R}^{n \times k}} \|W Z_3 - A_3\|_F^2 \leq (1+\epsilon)^3 \operatorname{OPT}.$$

Thus, we have

$$\min_{X_1, X_2, X_3} \|C^*((A_1 S_1 X_1), (A_2 S_2 X_2), (A_3 S_3 X_3)) - A\|_F^2 \leq (1+\epsilon)^3 \operatorname{OPT}.$$

Let $V_1 = A_1 S_1, V_2 = A_2 S_2$, and $V_3 = A_3 S_3$. We then apply Lemma 21.4.3, and we obtain $\widehat{V}_1, \widehat{V}_2, \widehat{V}_3, B$. We then apply Theorem 21.4.44. Correctness follows by rescaling ϵ by a constant factor.

Running time. Due to Definition 21.3.12, the running time of line 7 (Algorithm 21.33) is $O(\operatorname{nnz}(A)) + n \operatorname{poly}(k, 1/\epsilon)$. Due to Lemma 21.4.3, line 7 and 8 can be executed in $\operatorname{nnz}(A) + n \operatorname{poly}(k, 1/\epsilon)$ time. The running time of line 11 is given by Theorem 21.4.44. (For simplicity, we ignore the bit complexity in the running time.) □

21.10.2 Tensor Train rank

21.10.2.1 Definitions

The tensor train rank has been studied in several works [Ose11, OTZ11, ZWZ16, PTBD16]. We provide the formal definition here.

Definition 21.10.2 (Tensor Train rank)**.** Given a third order tensor $A \in \mathbb{R}^{n\times n\times n}$, we say A has train rank k if k is the smallest integer such that there exist three tensors $U \in \mathbb{R}^{1\times n\times k}$, $V \in \mathbb{R}^{k\times n\times k}$, $W \in \mathbb{R}^{k\times n\times 1}$ satisfying:

$$A_{i,j,l} = \sum_{i_1=1}^{1}\sum_{i_2=1}^{k}\sum_{i_3=1}^{k}\sum_{i_4=1}^{1} U_{i_1,i,i_2}V_{i_2,j,i_3}W_{i_3,l,i_4}, \forall i,j,l \in [n]\times[n]\times[n],$$

or equivalently,

$$A_{i,j,l} = \sum_{i_2=1}^{k}\sum_{i_3=1}^{k}(U_2)_{i,i_2}(V_2)_{j,i_2+k(i_3-1)}(W_2)_{l,i_3},$$

where $V_2 \in \mathbb{R}^{n\times k^2}$ denotes the matrix obtained by flattening the tensor U along the second dimension, and $(V_2)_{i,i_1+k(i_2-1)}$ denotes the entry in the i-th row and $i_1+k(i_2-1)$-th column of V_2. We similarly define $U_2, W_2 \in \mathbb{R}^{n\times k}$.

21.10.2.2 Algorithm

Theorem 21.10.2. *Given a third order tensor $A \in \mathbb{R}^{n\times n\times n}$, for any $k \geq 1$, $\epsilon \in (0,1)$, there exists an algorithm which takes $O(\mathrm{nnz}(A)) + n\,\mathrm{poly}(k, 1/\epsilon) + 2^{O(k^4/\epsilon)}$ time and outputs three tensors $U \in \mathbb{R}^{1\times n\times k}$, $V \in \mathbb{R}^{k\times n\times k}$, $W \in \mathbb{R}^{k\times n\times 1}$ such that*

$$\left\|\sum_{i=1}^{k}\sum_{j=1}^{k}(U_2)_i \otimes (V_2)_{i+k(j-1)} \otimes (W_2)_j - A\right\|_F^2 \leq (1+\epsilon)\min_{\text{train rank}-k\ A_k}\|A_k - A\|_F^2$$

holds with probability $9/10$.

  return $A_1 S_1 X_1$, $A_2 S_2 X_2$, and $A_3 S_3 X_3$.
end procedure

Proof. We define OPT as

$$\mathrm{OPT} = \min_{\text{train}} \min_{\text{rank}-k \ A'} \|A' - A\|_F^2.$$

Suppose the optimal

$$A_k = \sum_{i=1}^{k} \sum_{j=1}^{k} U_i^* \otimes V_{i+k(j-1)}^* \otimes W_j^*.$$

We fix $V^* \in \mathbb{R}^{n \times k^2}$ and $W^* \in \mathbb{R}^{n \times k}$. We use $V_1^*, V_2^*, \cdots, V_{k^2}^*$ to denote the columns of V^*, and $W_1^*, W_2^*, \cdots, W_k^*$ to denote the columns of W^*.

We consider the following optimization problem,

$$\min_{U \in \mathbb{R}^{n \times k}} \left\| \sum_{i=1}^{k} \sum_{j=1}^{k} U_i \otimes V_{i+k(j-1)}^* \otimes W_j^* - A \right\|_F^2,$$

which is equivalent to

$$\min_{U \in \mathbb{R}^{n \times k}} \left\| U \cdot \begin{bmatrix} \sum_{j=1}^{k} V_{1+k(j-1)}^* \otimes W_j^* \\ \sum_{j=1}^{k} V_{2+k(j-1)}^* \otimes W_j^* \\ \cdots \\ \sum_{j=1}^{k} V_{k+k(j-1)}^* \otimes W_j^* \end{bmatrix} - A \right\|_F^2.$$

Let $A_1 \in \mathbb{R}^{n \times n^2}$ denote the matrix obtained by flattening the tensor A along the first dimension. We use matrix $Z_1 \in \mathbb{R}^{k \times n^2}$ to denote

$$\begin{bmatrix} \sum_{j=1}^{k} \mathrm{vec}(V_{1+k(j-1)}^* \otimes W_j^*) \\ \sum_{j=1}^{k} \mathrm{vec}(V_{2+k(j-1)}^* \otimes W_j^*) \\ \cdots \\ \sum_{j=1}^{k} \mathrm{vec}(V_{k+k(j-1)}^* \otimes W_j^*) \end{bmatrix}.$$

Then we can obtain the following equivalent objective function,

$$\min_{U \in \mathbb{R}^{n \times k}} \|U Z_1 - A_1\|_F^2.$$

Notice that $\min_{U \in \mathbb{R}^{n \times k}} \|U Z_1 - A_1\|_F^2 = \mathrm{OPT}$, since $A_k = U^* Z_1$.

Let $S_1^\top \in \mathbb{R}^{s_1 \times n^2}$ be a sketching matrix defined in Definition 21.3.12, where $s_1 = O(k/\epsilon)$. We obtain the following optimization problem,

$$\min_{U \in \mathbb{R}^{n \times k}} \|U Z_1 S_1 - A_1 S_1\|_F^2.$$

Let $\widehat{U} \in \mathbb{R}^{n \times k}$ denote the optimal solution to the above optimization problem. Then $\widehat{U} = A_1 S_1 (Z_1 S_1)^\dagger$. By Lemma 21.3.10 and Theorem 21.3.11, we have

$$\|\widehat{U} Z_1 - A_1\|_F^2 \leq (1+\epsilon) \min_{U \in \mathbb{R}^{n \times k}} \|U Z_1 - A_1\|_F^2 = (1+\epsilon)\,\mathrm{OPT},$$

which implies

$$\left\| \sum_{i=1}^k \sum_{j=1}^k \widehat{U}_i \otimes V_{i+k(j-1)}^* \otimes W_j^* - A \right\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}\,.$$

To write down $\widehat{U}_1, \cdots, \widehat{U}_k$, we use the given matrix A_1, and we create $s_1 \times k$ variables for matrix $(Z_1 S_1)^\dagger$.

As our second step, we fix $\widehat{U} \in \mathbb{R}^{n \times k}$ and $W^* \in \mathbb{R}^{n \times k}$, and we convert the tensor A into matrix A_2. Let matrix $Z_2 \in \mathbb{R}^{k^2 \times n^2}$ denote the matrix where the (i,j)-th row is the vectorization of $\widehat{U}_i \otimes W_j^*$. We consider the following objective function,

$$\min_{V \in \mathbb{R}^{n \times k}} \|V Z_2 - A_2\|_F^2,$$

for which the optimal cost is at most $(1+\epsilon)\,\mathrm{OPT}$.

Let $S_2^\top \in \mathbb{R}^{s_2 \times n^2}$ be a sketching matrix defined in Definition 21.3.12, where $s_2 = O(k^2/\epsilon)$. We sketch S_2 on the right of the objective function to obtain the new objective function,

$$\min_{V \in \mathbb{R}^{n \times k}} \|V Z_2 S_2 - A_2 S_2\|_F^2.$$

Let $\widehat{V} \in \mathbb{R}^{n \times k}$ denote the optimal solution of the above problem. Then $\widehat{V} = A_2 S_2 (Z_2 S_2)^\dagger$. By Lemma 21.3.10 and Theorem 21.3.11, we have,

$$\|\widehat{V} Z_2 - A_2\|_F^2 \leq (1+\epsilon) \min_{V \in \mathbb{R}^{n \times k}} \|V Z_2 - A_2\|_F^2 \leq (1+\epsilon)^2\,\mathrm{OPT},$$

which implies

$$\left\| \sum_{i=1}^k \sum_{j=1}^k \widehat{U}_i \otimes \widehat{V}_{i+k(j-1)} \otimes W^* - A \right\|_F^2 \leq (1+\epsilon)^2\,\mathrm{OPT}\,.$$

To write down $\widehat{V}_1, \cdots, \widehat{V}_k$, we need to use the given matrix $A_2 \in \mathbb{R}^{n^2 \times n}$, and we need to create $s_2 \times k$ variables for matrix $(Z_2 S_2)^\dagger$.

As our third step, we fix the matrices $\widehat{U} \in \mathbb{R}^{n \times k}$ and $\widehat{V} \in \mathbb{R}^{n \times k}$. We convert tensor $A \in \mathbb{R}^{n \times n \times n}$ into matrix $A_3 \in \mathbb{R}^{n^2 \times n}$. Let matrix $Z_3 \in \mathbb{R}^{k \times n^2}$ denote

$$\begin{bmatrix} \sum_{i=1}^k \mathrm{vec}(\widehat{U}_i \otimes \widehat{V}_{i+k\cdot 0}) \\ \sum_{i=1}^k \mathrm{vec}(\widehat{U}_i \otimes \widehat{V}_{i+k\cdot 1}) \\ \cdots \\ \sum_{i=1}^k \mathrm{vec}(\widehat{U}_i \otimes \widehat{V}_{i+k\cdot(k-1)}) \end{bmatrix}.$$

We consider the following objective function,

$$\min_{W \in \mathbb{R}^{n \times k}} \|W Z_3 - A_3\|_F^2,$$

which has optimal cost at most $(1+\epsilon)^2$ OPT.

Let $S_3^\top \in \mathbb{R}^{s_3 \times n^2}$ be a sketching matrix defined in Definition 21.3.12, where $s_3 = O(k/\epsilon)$. We sketch S_3 on the right of the objective function to obtain a new objective function,

$$\min_{W \in \mathbb{R}^{n \times k}} \|W Z_3 S_3 - A_3 S_3\|_F^2.$$

Let $\widehat{W} \in \mathbb{R}^{n \times k}$ denote the optimal solution of the above problem. Then $\widehat{W} = A_3 S_3 (Z_3 S_3)^\dagger$. By Lemma 21.3.10 and Theorem 21.3.11, we have,

$$\|\widehat{W} Z_3 - A_3\|_F^2 \leq (1+\epsilon) \min_{W \in \mathbb{R}^{n \times k}} \|W Z_3 - A_3\|_F^2 \leq (1+\epsilon)^3 \, \mathrm{OPT} \, .$$

Thus, we have

$$\min_{X_1, X_2, X_3} \left\| \sum_{i=1}^k \sum_{j=1}^k (A_1 S_1 X_1)_i \otimes (A_2 S_2 X_2)_{i+k(j-1)} \otimes (A_3 S_3 X_3)_j - A \right\|_F^2 \leq (1+\epsilon)^3 \, \mathrm{OPT} \, .$$

Let $V_1 = A_1 S_1, V_2 = A_2 S_2$, and $V_3 = A_3 S_3$. We then apply Lemma 21.4.3, and we obtain $\widehat{V}_1, \widehat{V}_2, \widehat{V}_3, B$. We then apply Theorem 21.4.44. Correctness follows by rescaling ϵ by a constant factor.

Running time. Due to Definition 21.3.12, the running time of line 7 (Algorithm 21.34) is $O(\mathrm{nnz}(A)) + n \, \mathrm{poly}(k, 1/\epsilon)$. Due to Lemma 21.4.3, lines 8 and 9 can be executed in $\mathrm{nnz}(A) + n \, \mathrm{poly}(k, 1/\epsilon)$ time. The running time of $2^{O(k^4/\epsilon)}$ comes from running Theorem 21.4.44 (For simplicity, we ignore the bit complexity in the running time.) □

21.11 Entry-wise ℓ_p Norm for Arbitrary Tensors, $1 < p < 2$

There is a long line of research dealing with ℓ_p norm-related problems [DDH+09, MM13, CDMI+13, CP15, BCKY16, YCRM16, BBC+17].

In this section, we provide several different algorithms for tensor ℓ_p-low rank approximation. Section 21.11.1 formally states the ℓ_p version of Theorem C.1 in [SWZ17]. Section 21.11.2 presents several existence results. Section 21.11.3 describes a tool that is able to reduce the size of the objective function from poly(n) to poly(k). Section 21.11.4 discusses the case when the problem size is small. Section 21.11.5 provides several bicriteria algorithms. Section 21.11.6 summarizes a batch of algorithms. Section 21.11.7 provides an algorithm for ℓ_p norm CURT decomposition.

Notice that if the rank-k solution does not exist, then every bicriteria algorithm in Section 21.11.5 can be stated in the form as Theorem 21.1.1, and every algorithm which can output a rank-k solution in Section 21.11.6 can be stated in the form as Theorem 21.1.2. See Section 21.1 for more details.

21.11.1 Existence results for matrix case

Theorem 21.11.1 ([SWZ17]). *Let $1 \leq p < 2$. Given $V \in \mathbb{R}^{k\times n}, A \in \mathbb{R}^{d\times n}$. Let $S \in \mathbb{R}^{n\times s}$ be a proper random sketching matrix. Let*

$$\widehat{U} = \arg\min_{U\in\mathbb{R}^{d\times k}} \|UVS - AS\|_F^2,$$

i.e.,

$$\widehat{U} = AS(VS)^\dagger.$$

Then with probability at least 0.999,

$$\|\widehat{U}V - A\|_p^p \leq \alpha \cdot \min_{U\in\mathbb{R}^{d\times k}} \|UV - A\|_p^p.$$

(I). *S denotes a dense p-stable transform,*
$s = \widetilde{O}(k)$, $\alpha = \widetilde{O}(k^{1-p/2})\log d$.

(II). *S denotes a sparse p-stable transform,*
$s = \widetilde{O}(k^5)$, $\alpha = \widetilde{O}(k^{5-5p/2+2/p})\log d$.

(III). *$S^\top$ denotes a sampling/rescaling matrix according to the ℓ_p Lewis weights of $V^\top$,*
$s = \widetilde{O}(k)$, $\alpha = \widetilde{O}(k^{1-p/2})$.

We give the proof for completeness.

Proof. Let $S \in \mathbb{R}^{n\times s}$ be a sketching matrix which satisfies the property $(*)$: $\forall c \geq 1, \widetilde{U} \in \mathbb{R}^{d\times k}$ which satisfy

$$\|\widetilde{U}VS - AS\|_p^p \leq c \cdot \min_{U\in\mathbb{R}^{d\times k}} \|UVS - AS\|_p^p,$$

we have

$$\|\widetilde{U}V - A\|_p^p \leq c\beta_S \cdot \min_{U \in \mathbb{R}^{d \times k}} \|UV - A\|_p^p,$$

where $\beta_S \geq 1$ only depends on the sketching matrix S. Let

$$\forall i \in [d], (\widehat{U}^i)^\top = \arg\min_{x \in \mathbb{R}^k} \|x^\top VS - A^i S\|_2^2,$$

i.e.,

$$\widehat{U} = AS(VS)^\dagger.$$

Let

$$\widetilde{U} = \arg\min_{U \in \mathbb{R}^{d \times k}} \|UVS - AS\|_p^p.$$

Then, we have:

$$\begin{aligned}
& \|\widehat{U}VS - AS\|_p^p \\
= & \sum_{i=1}^{d} \|\widehat{U}^i VS - A^i S\|_p^p \\
\leq & \sum_{i=1}^{d} (s^{1/p-1/2} \|\widehat{U}^i VS - A^i S\|_2)^p \\
\leq & \sum_{i=1}^{d} (s^{1/p-1/2} \|\widetilde{U}^i VS - A^i S\|_2)^p \\
\leq & \sum_{i=1}^{d} (s^{1/p-1/2} \|\widetilde{U}^i VS - A^i S\|_p)^p \\
\leq & s^{1-p/2} \|\widetilde{U}VS - AS\|_p^p.
\end{aligned}$$

The first inequality follows using $\forall x \in \mathbb{R}^s, \|x\|_p \leq s^{1/p-1/2}\|x\|_2$ since $p < 2$. The third inequality follows using $\forall x \in \mathbb{R}^s, \|x\|_2 \leq \|x\|_p$ since $p < 2$. Thus, according to the property $(*)$ of S,

$$\|\widehat{U}V - A\|_p^p \leq s^{1-p/2}\beta_S \min_{U \in \mathbb{R}^{d\times k}} \|UV - A\|_p^p.$$

Due to Lemma E.8 and Lemma E.11 of [SWZ17], we have:

for (I), $s = \widetilde{O}(k), \beta_S = O(\log d), \alpha = s^{1-p/2}\beta_S = \widetilde{O}(k^{1-p/2})\log d$,

for (II), $s = \widetilde{O}(k^5), \beta_S = \widetilde{O}(k^{2/p}\log d), \alpha = s^{1-p/2}\beta_S = \widetilde{O}(k^{5-5p/2+2/p})\log d$,

for (III), $s = \widetilde{O}(k), \beta_S = O(1), \alpha = s^{1-p/2}\beta_S = \widetilde{O}(k^{1-p/2})$. □

21.11.2 Existence results

Theorem 21.11.2. *Given a 3rd order tensor $A \in \mathbb{R}^{n\times n\times n}$, for any $k \geq 1$, there exist three matrices $S_1 \in \mathbb{R}^{n^2\times s_1}$, $S_2 \in \mathbb{R}^{n^2\times s_2}$, $S_3 \in \mathbb{R}^{n^2\times s_3}$ such that*

$$\min_{X_1,X_2,X_3} \left\| \sum_{i=1}^{k} (A_1S_1X_1)_i \otimes (A_2S_2X_2)_i \otimes (A_3S_3X_3)_i - A \right\|_p^p \leq \alpha \min_{\mathrm{rank}-k \ A_k\in\mathbb{R}^{n\times n\times n}} \|A_k - A\|_p^p,$$

holds with probability $99/100$.

(I). *Using a dense p-stable transform,*
$s_1 = s_2 = s_3 = \widetilde{O}(k)$, $\alpha = \widetilde{O}(k^{3-1.5p}) \log^3 n$.

(II). *Using a sparse p-stable transform,*
$s_1 = s_2 = s_3 = \widetilde{O}(k^5)$, $\alpha = \widetilde{O}(k^{15-7.5p+6/p}) \log^3 n$.

(III). *Guessing Lewis weights,*
$s_1 = s_2 = s_3 = \widetilde{O}(k)$, $\alpha = \widetilde{O}(k^{3-1.5p})$.

Proof. We use OPT to denote

$$\mathrm{OPT} := \min_{\mathrm{rank}-k \ A_k\in\mathbb{R}^{n\times n\times n}} \|A_k - A\|_p^p.$$

Given a tensor $A \in \mathbb{R}^{n_1\times n_2\times n_3}$, we define three matrices $A_1 \in \mathbb{R}^{n_1\times n_2n_3}$, $A_2 \in \mathbb{R}^{n_2\times n_3n_1}$, $A_3 \in \mathbb{R}^{n_3\times n_1n_2}$ such that, for any $i \in [n_1], j \in [n_2], l \in [n_3]$

$$A_{i,j,l} = (A_1)_{i,(j-1)\cdot n_3+l} = (A_2)_{j,(l-1)\cdot n_1+i} = (A_3)_{l,(i-1)\cdot n_2+j}.$$

We fix $V^* \in \mathbb{R}^{n\times k}$ and $W^* \in \mathbb{R}^{n\times k}$, and use $V_1^*, V_2^*, \cdots, V_k^*$ to denote the columns of V^* and $W_1^*, W_2^*, \cdots, W_k^*$ to denote the columns of W^*.

We consider the following optimization problem,

$$\min_{U_1,\cdots,U_k\in\mathbb{R}^n}\left\|\sum_{i=1}^k U_i\otimes V_i^*\otimes W_i^* - A\right\|_p^p,$$

which is equivalent to

$$\min_{U_1,\cdots,U_k\in\mathbb{R}^n}\left\|\begin{bmatrix}U_1 & U_2 & \cdots & U_k\end{bmatrix}\begin{bmatrix}V_1^*\otimes W_1^*\\ V_2^*\otimes W_2^*\\ \cdots\\ V_k^*\otimes W_k^*\end{bmatrix} - A\right\|_p^p.$$

We use matrix Z_1 to denote $V^{*\top}\odot W^{*\top}\in\mathbb{R}^{k\times n^2}$ and matrix U to denote $\begin{bmatrix}U_1 & U_2 & \cdots & U_k\end{bmatrix}$. Then we can obtain the following equivalent objective function,

$$\min_{U\in\mathbb{R}^{n\times k}}\|UZ_1 - A_1\|_p^p.$$

Choose a sketching matrix (a dense p-stable, a sparse p-stable or an ℓ_p Lewis weight sampling/rescaling matrix to Z_1) $S_1\in\mathbb{R}^{n^2\times s_1}$. We can obtain the optimization problem,

$$\min_{U\in\mathbb{R}^{n\times k}}\|UZ_1S_1 - A_1S_1\|_p^p = \min_{U\in\mathbb{R}^{n\times k}}\sum_{i=1}^n\|U^iZ_1S_1 - (A_1S_1)^i\|_p^p,$$

where U^i denotes the i-th row of matrix $U\in\mathbb{R}^{n\times k}$ and $(A_1S_1)^i$ denotes the i-th row of matrix A_1S_1. Instead of solving it under the ℓ_p-norm, we consider the ℓ_2-norm relaxation,

$$\min_{U\in\mathbb{R}^{n\times k}}\|UZ_1S_1 - A_1S_1\|_F^2 = \min_{U\in\mathbb{R}^{n\times k}}\sum_{i=1}^n\|U^iZ_1S_1 - (A_1S_1)^i\|_2^2.$$

Let $\widehat{U}\in\mathbb{R}^{n\times k}$ denote the optimal solution of the above optimization problem. Then, $\widehat{U} = A_1S_1(Z_1S_1)^\dagger$. We plug $\widehat{U}$ into the objective function under the ℓ_p-norm. By choosing s_1 and by the properties of sketching matrices (a dense p-stable, a sparse p-stable or an ℓ_p Lewis weight sampling/rescaling matrix to Z_1) $S_1\in\mathbb{R}^{n^2\times s_1}$, we have

$$\|\widehat{U}Z_1 - A_1\|_p^p \le \alpha\min_{U\in\mathbb{R}^{n\times k}}\|UZ_1 - A_1\|_p^p = \alpha\,\mathrm{OPT}\,.$$

This implies

$$\|\widehat{U} \otimes V^* \otimes W^* - A\|_p^p \leq \alpha \, \mathrm{OPT} \, .$$

As a second step, we fix $\widehat{U} \in \mathbb{R}^{n \times k}$ and $W^* \in \mathbb{R}^{n \times k}$, and convert tensor A into matrix A_2. Let matrix Z_2 denote $\widehat{U}^\top \odot W^{*\top}$. We consider the following objective function,

$$\min_{V \in \mathbb{R}^{n \times k}} \|V Z_2 - A_2\|_p^p,$$

and the optimal cost of it is at most $\alpha \, \mathrm{OPT}$.

We choose a sketching matrix (a dense p-stable, a sparse p-stable or an ℓ_p Lewis weight sampling/rescaling matrix to Z_2) $S_2 \in \mathbb{R}^{n^2 \times s_2}$ and sketch on the right of the objective function to obtain the new objective function,

$$\min_{V \in \mathbb{R}^{n \times k}} \|V Z_2 S_2 - A_2 S_2\|_p^p = \min_{V \in \mathbb{R}^{n \times k}} \sum_{i=1}^n \|V^i Z_2 S_2 - (A_2 S_2)^i\|_p^p,$$

where V^i denotes the i-th row of matrix V and $(A_2 S_2)^i$ denotes the i-th row of matrix $A_2 S_2$. Instead of solving this under the ℓ_p-norm, we consider the ℓ_2-norm relaxation,

$$\min_{V \in \mathbb{R}^{n \times k}} \|V Z_2 S_2 - A_2 S_2\|_F^2 = \min_{V \in \mathbb{R}^{n \times k}} \sum_{i=1}^n \|V^i (Z_2 S_2) - (A_2 S_2)^i\|_2^2.$$

Let $\widehat{V} \in \mathbb{R}^{n \times k}$ denote the optimal solution of the above problem. Then $\widehat{V} = A_2 S_2 (Z_2 S_2)^\dagger$. By properties of sketching matrix $S_2 \in \mathbb{R}^{n^2 \times s_2}$, we have,

$$\|\widehat{V} Z_2 - A_2\|_p^p \leq \alpha \min_{V \in \mathbb{R}^{n \times k}} \|V Z_2 - A_2\|_p^p \leq \alpha^2 \, \mathrm{OPT},$$

which implies

$$\|\widehat{U} \otimes \widehat{V} \otimes W^* - A\|_p^p \leq \alpha^2 \, \mathrm{OPT},$$

As a third step, we fix the matrices $\widehat{U} \in \mathbb{R}^{n \times k}$ and $\widehat{V} \in \mathbb{R}^{n \times k}$. We can convert tensor $A \in \mathbb{R}^{n \times n \times n}$ into matrix $A_3 \in \mathbb{R}^{n^2 \times n}$. Let matrix Z_3 denote $\widehat{U}^\top \odot \widehat{V}^\top \in \mathbb{R}^{k \times n^2}$. We consider the following objective function,

$$\min_{W \in \mathbb{R}^{n \times k}} \|W Z_3 - A_3\|_p^p,$$

and the optimal cost of it is at most $\alpha^2 \, \mathrm{OPT}$.

We choose sketching matrix (a dense p-stable, a sparse p-stable or an ℓ_p Lewis weight sampling/rescaling matrix to Z_3) $S_3 \in \mathbb{R}^{n^2 \times s_3}$ and sketch on the right of the objective function to obtain the new objective function,

$$\min_{W \in \mathbb{R}^{n \times k}} \|W Z_3 S_3 - A_3 S_3\|_p^p.$$

Instead of solving this under the ℓ_p-norm, we consider the ℓ_2-norm relaxation,

$$\min_{W \in \mathbb{R}^{n \times k}} \|W Z_3 S_3 - A_3 S_3\|_F^2 = \min_{W \in \mathbb{R}^{n \times k}} \sum_{i=1}^n \|W^i (Z_3 S_3) - (A_3 S_3)^i\|_2^2.$$

Let $\widehat{W} \in \mathbb{R}^{n \times k}$ denote the optimal solution of the above problem. Then $\widehat{W} = A_3 S_3 (Z_3 S_3)^\dagger$. By properties of sketching matrix $S_3 \in \mathbb{R}^{n^2 \times s_3}$, we have,

$$\|\widehat{W} Z_3 - A_3\|_p^p \leq \alpha \min_{W \in \mathbb{R}^{n \times k}} \|W Z_3 - A_3\|_p^p \leq \alpha^3 \, \mathrm{OPT} \, .$$

Thus, we obtain,

$$\min_{X_1 \in \mathbb{R}^{s_1 \times k}, X_2 \in \mathbb{R}^{s_2 \times k}, X_3 \in \mathbb{R}^{s_3 \times k}} \left\| \sum_{i=1}^k (A_1 S_1 X_1)_i \otimes (A_2 S_2 X_2)_i \otimes (A_3 S_3 X_3)_i - A \right\|_p^p \leq \alpha^3 \, \mathrm{OPT} \, .$$

According to Theorem 21.11.1, we let $s = s_1 = s_2 = s_3$ and take the corresponding α. We can directly get the results for (I), (II) and (III). $\square$

21.11.3 Polynomial in k size reduction

Definition 21.11.1 (Definition E.1 in [SWZ17])**.** Given a matrix $M \in \mathbb{R}^{n\times d}$, if matrix $S \in \mathbb{R}^{m\times n}$ satisfies

$$\|SM\|_p^p \leq \beta \|M\|_p^p,$$

then S has at most β dilation on M in the ℓ_p case.

Definition 21.11.2 (Definition E.2 in [SWZ17])**.** Given a matrix $U \in \mathbb{R}^{n\times k}$, if matrix $S \in \mathbb{R}^{m\times n}$ satisfies

$$\forall x \in \mathbb{R}^k, \|SUx\|_p^p \geq \frac{1}{\beta}\|Ux\|_p^p,$$

then S has at most β contraction on U in the ℓ_p case.

Theorem 21.11.3. *Given a tensor $A \in \mathbb{R}^{n_1\times n_2\times n_3}$ and three matrices $V_1 \in \mathbb{R}^{n_1\times b_1}, V_2 \in \mathbb{R}^{n_2\times b_2}, V_3 \in \mathbb{R}^{n_3\times b_3}$, let $X_1^* \in \mathbb{R}^{b_1\times k}, X_2^* \in \mathbb{R}^{b_2\times k}, X_3^* \in \mathbb{R}^{b_3\times k}$ satisfy*

$$X_1^*, X_2^*, X_3^* = \mathop{\arg\min}_{X_1\in\mathbb{R}^{b_1\times k}, X_2\in\mathbb{R}^{b_2\times k}, X_3\in\mathbb{R}^{b_3\times k}} \|V_1X_1 \otimes V_2X_2 \otimes V_3X_3 - A\|_p^p.$$

Let $S \in \mathbb{R}^{m\times n}$ have at most $\beta_1 \geq 1$ dilation on $V_1X_1^* \cdot ((V_2X_2^*)^\top \odot (V_3X_3^*)^\top) - A_1$ and S have at most $\beta_2 \geq 1$ contraction on V_1 in the ℓ_p case. If $\widehat{X}_1 \in \mathbb{R}^{b_1\times k}, \widehat{X}_2 \in \mathbb{R}^{b_2\times k}, \widehat{X}_3 \in \mathbb{R}^{b_3\times k}$ satisfy

$$\|SV_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - SA\|_p^p \leq \beta \min_{X_1\in\mathbb{R}^{b_1\times k}, X_2\in\mathbb{R}^{b_2\times k}, X_3\in\mathbb{R}^{b_3\times k}} \|SV_1X_1 \otimes V_2X_2 \otimes V_3X_3 - SA\|_p^p,$$

where $\beta \geq 1$, then

$$\|V_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - A\|_p^p \lesssim \beta_1\beta_2\beta \min_{X_1,X_2,X_3} \|V_1X_1 \otimes V_2X_2 \otimes V_3X_3 - A\|_p^p.$$

The proof is essentially the same as the proof of Theorem 21.7.4:

Proof. Let $A, V_1, V_2, V_3, S, X_1^*, X_2^*, X_3^*, \beta_1, \beta_2$ be as stated in the theorem. Let $\widehat{X}_1 \in \mathbb{R}^{b_1 \times k}, \widehat{X}_2 \in \mathbb{R}^{b_2 \times k}, \widehat{X}_3 \in \mathbb{R}^{b_3 \times k}$ satisfy

$$\|SV_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - SA\|_p^p \leq \beta \min_{X_1 \in \mathbb{R}^{b_1 \times k}, X_2 \in \mathbb{R}^{b_2 \times k}, X_3 \in \mathbb{R}^{b_3 \times k}} \|SV_1X_1 \otimes V_2X_2 \otimes V_3X_3 - SA\|_p^p.$$

Similar to the proof of Theorem 21.7.4, we have,

$$\begin{aligned}
&\|SV_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - SA\|_p^p \\
&= 2^{2-2p}\frac{1}{\beta_2}\|V_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - A\|_p^p - (2^{1-p}\frac{1}{\beta_2} + \beta_1)\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_p^p
\end{aligned}$$

The only difference from the proof of Theorem 21.7.4 is that instead of using triangle inequality, we actually use $\|x+y\|_p^p \leq 2^{p-1}\|x\|_p^p + \|y\|_p^p$. Then, we have

$$\begin{aligned}
&\|V_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - A\|_p^p \\
&\leq 2^{2p-2}\beta_2\|SV_1\widehat{X}_1 \otimes V_2\widehat{X}_2 \otimes V_3\widehat{X}_3 - SA\|_p^p + (2^{p-1} + 2^{2p-2}\beta_1\beta_2)\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_p^p \\
&\leq 2^{2p-2}\beta_2\beta\|SV_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - SA\|_p^p + (2^{p-1} + 2^{2p-2}\beta_1\beta_2)\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_p^p \\
&\leq 2^{2p-2}\beta_1\beta_2\beta\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_p^p + (2^{p-1} + 2^{2p-2}\beta_1\beta_2)\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_p^p \\
&\leq 2^{p-1}\beta(1 + 2\beta_1\beta_2)\|V_1X_1^* \otimes V_2X_2^* \otimes V_3X_3^* - A\|_p^p.
\end{aligned}$$

□

Lemma 21.11.4. *Let* $\min(b_1, b_2, b_3) \geq k$. *Given three matrices* $V_1 \in \mathbb{R}^{n \times b_1}$, $V_2 \in \mathbb{R}^{n \times b_2}$, *and* $V_3 \in \mathbb{R}^{n \times b_3}$, *there exists an algorithm which takes* $O(\mathrm{nnz}(A)) + n\,\mathrm{poly}(b_1, b_2, b_3)$ *time and outputs a tensor* $C \in \mathbb{R}^{c_1 \times c_2 \times c_3}$ *and three matrices* $\widehat{V}_1 \in \mathbb{R}^{c_1 \times b_1}$, $\widehat{V}_2 \in \mathbb{R}^{c_2 \times b_2}$ *and* $\widehat{V}_3 \in \mathbb{R}^{c_3 \times b_3}$

with $c_1 = c_2 = c_3 = \mathrm{poly}(b_1, b_2, b_3)$*, such that with probability* 0.99*, for any* $\alpha \geq 1$*, if* X_1', X_2', X_3' *satisfy that,*

$$\left\| \sum_{i=1}^{k} (\widehat{V}_1 X_1')_i \otimes (\widehat{V}_2 X_2')_i \otimes (\widehat{V}_3 X_3')_i - C \right\|_p^p \leq \alpha \min_{X_1, X_2, X_3} \left\| \sum_{i=1}^{k} (\widehat{V}_1 X_1)_i \otimes (\widehat{V}_2 X_2)_i \otimes (\widehat{V}_3 X_3)_i - C \right\|_p^p,$$

then,

$$\left\| \sum_{i=1}^{k} (V_1 X_1')_i \otimes (V_2 X_2')_i \otimes (V_3 X_3')_i - A \right\|_p^p \lesssim \alpha \min_{X_1, X_2, X_3} \left\| \sum_{i=1}^{k} (V_1 X_1)_i \otimes (V_2 X_2)_i \otimes (V_3 X_3)_i - A \right\|_p^p.$$

Proof. For simplicity, we define OPT to be

$$\min_{X_1, X_2, X_3} \left\| \sum_{i=1}^{k} (V_1 X_1)_i \otimes (V_2 X_2)_i \otimes (V_3 X_3)_i - A \right\|_p^p.$$

Let $T_1 \in \mathbb{R}^{c_1 \times n}$ correspond to sampling according to the ℓ_p Lewis weights of $V_1 \in \mathbb{R}^{n \times b_1}$, where $c_1 = \widetilde{b_1}$. Let $T_2 \in \mathbb{R}^{c_2 \times n}$ be sampling according to the ℓ_p Lewis weights of $V_2 \in \mathbb{R}^{n \times b_2}$, where $c_2 = \widetilde{b_2}$. Let $T_3 \in \mathbb{R}^{c_3 \times n}$ be sampling according to the ℓ_p Lewis weights of $V_3 \in \mathbb{R}^{n \times b_3}$, where $c_3 = \widetilde{b_3}$.

For any $\alpha \geq 1$, let $X_1' \in \mathbb{R}^{b_1 \times k}, X_2' \in \mathbb{R}^{b_2 \times k}, X_3' \in \mathbb{R}^{b_3 \times k}$ satisfy

$$\begin{aligned} &\|T_1 V_1 X_1' \otimes T_2 V_2 X_2' \otimes T_3 V_3 X_3' - A(T_1, T_2, T_3)\|_p^p \\ \leq\ & \alpha \min_{X_1 \in \mathbb{R}^{b_1 \times k}, X_2 \in \mathbb{R}^{b_2 \times k}, X_3 \in \mathbb{R}^{b_3 \times k}} \|T_1 V_1 X_1 \otimes T_2 V_2 X_2 \otimes T_3 V_3 X_3 - A(T_1, T_2, T_3)\|_p^p. \end{aligned}$$

First, we regard T_1 as the sketching matrix for the remainder. Then by Lemma D.11 in [SWZ17] and Theorem 21.7.4, we have

$$\begin{aligned} &\|V_1 X_1' \otimes T_2 V_2 X_2' \otimes T_3 V_3 X_3' - A(I, T_2, T_3)\|_p^p \\ \lesssim\ & \alpha \min_{X_1 \in \mathbb{R}^{b_1 \times k}, X_2 \in \mathbb{R}^{b_2 \times k}, X_3 \in \mathbb{R}^{b_3 \times k}} \|V_1 X_1 \otimes T_2 V_2 X_2 \otimes T_3 V_3 X_3 - A(I, T_2, T_3)\|_p^p. \end{aligned}$$

Second, we regard T_2 as the sketching matrix for $V_1X_1 \otimes V_2X_2 \otimes T_3V_3X_3 - A(I, I, T_3)$. Then by Lemma D.11 in [SWZ17] and Theorem 21.7.4, we have

$$\begin{aligned}
&\|V_1X_1' \otimes V_2X_2' \otimes T_3V_3X_3' - A(I, I, T_3)\|_p^p \\
\lesssim\ &\alpha \min_{X_1 \in \mathbb{R}^{b_1 \times k}, X_2 \in \mathbb{R}^{b_2 \times k}, X_3 \in \mathbb{R}^{b_3 \times k}} \|V_1X_1 \otimes V_2X_2 \otimes T_3V_3X_3 - A(I, I, T_3)\|_p^p.
\end{aligned}$$

Third, we regard T_3 as the sketching matrix for $V_1X_1 \otimes V_2X_2 \otimes V_3X_3 - A$. Then by Lemma D.11 in [SWZ17] and Theorem 21.7.4, we have

$$\left\|\sum_{i=1}^k (V_1X_1')_i \otimes (V_2X_2')_i \otimes (V_3X_3')_i - A\right\|_p^p \lesssim \alpha \min_{X_1, X_2, X_3} \left\|\sum_{i=1}^k (V_1X_1)_i \otimes (V_2X_2)_i \otimes (V_3X_3)_i - A\right\|_p^p.$$

□

21.11.4 Solving small problems

Combining Section B.5 in [SWZ17] and the proof of Theorem 21.7.4, for any $p = a/b$ with a, b are integers, we can obtain the ℓ_p version of Theorem 21.7.4.

21.11.5 Bicriteria algorithm

We present several bicriteria algorithms with different tradeoffs. We first present an algorithm that runs in nearly linear time and outputs a solution with rank $\widetilde{O}(k^3)$ in Theorem 21.11.5. Then we show an algorithm that runs in $\mathrm{nnz}(A)$ time but outputs a solution with rank $\mathrm{poly}(k)$ in Theorem 21.11.6. Then we explain an idea which is able to decrease the cubic rank to quadratic, and thus we can obtain Theorem 21.11.7.

Theorem 21.11.5. *Given a 3rd order tensor $A \in \mathbb{R}^{n\times n\times n}$, for any $k \geq 1$, let $r = \widetilde{O}(k^3)$. There exists an algorithm which takes $\mathrm{nnz}(A) \cdot \widetilde{O}(k) + n\,\mathrm{poly}(k) + \mathrm{poly}(k)$ time and outputs three matrices $U, V, W \in \mathbb{R}^{n\times r}$ such that*

$$\left\| \sum_{i=1}^{r} U_i \otimes V_i \otimes W_i - A \right\|_p^p \leq \widetilde{O}(k^{3-p/2}) \log^3 n \min_{\mathrm{rank}-k\ A_k} \|A_k - A\|_p^p$$

holds with probability $9/10$.

Proof. We first choose three dense Cauchy transforms $S_i \in \mathbb{R}^{n^2\times s_i}$. According to Section 21.3.7, for each $i \in [3]$, $A_i S_i$ can be computed in $\mathrm{nnz}(A) \cdot \widetilde{O}(k)$ time. Then we apply Lemma 21.11.4. We obtain three matrices $Y_1 = T_1 A_1 S_1, Y_2 = T_2 A_2 S_2, Y_3 = T_3 A_3 S_3$ and a tensor $C = A(T_1, T_2, T_3)$. Note that for each $i \in [3]$, Y_i can be computed in $n\,\mathrm{poly}(k)$ time. Because $C = A(T_1, T_2, T_3)$ and $T_1, T_2, T_3 \in \mathbb{R}^{n\times \widetilde{O}(k)}$ are three sampling and rescaling matrices, C can be computed in $\mathrm{nnz}(A) + \widetilde{O}(k^3)$ time. At the end, we just need to run an ℓ_p-regression solver to find the solution for the problem:

$$\min_{X\in\mathbb{R}^{s_1\times s_2\times s_3}} \left\| \sum_{i=1}^{s_1}\sum_{j=1}^{s_2}\sum_{l=1}^{s_3} X_{i,j,l} (Y_1)_i \otimes (Y_2)_j \otimes (Y_3)_j \right\|_p^p,$$

where $(Y_1)_i$ denotes the i-th column of matrix Y_1. Since the size of the above problem is only $\mathrm{poly}(k)$, this can be solved in $\mathrm{poly}(k)$ time. □

Theorem 21.11.6. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$, let $r = \widetilde{O}(k^{15})$. There exists an algorithm that takes $\mathrm{nnz}(A) + n\,\mathrm{poly}(k) + \mathrm{poly}(k)$ time and outputs three matrices $U, V, W \in \mathbb{R}^{n \times r}$ such that*

$$\left\| \sum_{i=1}^{r} U_i \otimes V_i \otimes W_i - A \right\|_p^p \leq \mathrm{poly}(k, \log n) \min_{\mathrm{rank}-k \ A_k} \|A_k - A\|_p^p$$

holds with probability 9/10.

Proof. We first choose three sparse p-stable transforms $S_i \in \mathbb{R}^{n^2 \times s_i}$. According to Section 21.3.7, for each $i \in [3]$, $A_i S_i$ can be computed in $O(\mathrm{nnz}(A))$ time. Then we apply Lemma 21.11.4, and can obtain three matrices $Y_1 = T_1 A_1 S_1, Y_2 = T_2 A_2 S_2, Y_3 = T_3 A_3 S_3$ and a tensor $C = A(T_1, T_2, T_3)$. Note that for each $i \in [3]$, Y_i can be computed in $n\,\mathrm{poly}(k)$ time. Because $C = A(T_1, T_2, T_3)$ and $T_1, T_2, T_3 \in \mathbb{R}^{n \times \widetilde{O}(k)}$ are three sampling and rescaling matrices, C can be computed in $\mathrm{nnz}(A) + \widetilde{O}(k^3)$ time. At the end, we just need to run an ℓ_p-regression solver to find the solution to the problem,

$$\min_{X \in \mathbb{R}^{s_1 \times s_2 \times s_3}} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} X_{i,j,l} (Y_1)_i \otimes (Y_2)_j \otimes (Y_3)_l - C \right\|_p^p,$$

where $(Y_1)_i$ denotes the i-th column of matrix Y_1. Since the size of the above problem is only $\mathrm{poly}(k)$, it can be solved in $\mathrm{poly}(k)$ time. □

Theorem 21.11.7. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$, $\epsilon \in (0, 1)$, let $r = \widetilde{O}(k^2)$. There exists an algorithm which takes $\mathrm{nnz}(A) \cdot \widetilde{O}(k) + n\,\mathrm{poly}(k) + \mathrm{poly}(k)$ time and outputs three matrices $U, V, W \in \mathbb{R}^{n \times r}$ such that*

$$\left\| \sum_{i=1}^{r} U_i \otimes V_i \otimes W_i - A \right\|_p^p \leq \widetilde{O}(k^{3-1.5p}) \log^3 n \min_{\mathrm{rank}-k \ A_k} \|A_k - A\|_p^p$$

holds with probability 9/10.

Proof. The proof is similar to Theorem 21.7.11. □

procedure LpBicriteriaAlgorithm(A, n, k) ▷ Corollary 21.11.8
  $s_1 \leftarrow s_2 \leftarrow s_3 \leftarrow \widetilde{O}(k)$.
  For each $i \in [3]$, choose $S_i \in \mathbb{R}^{n^2 \times s_i}$ to be the composition of a sparse p-stable transform and a dense p-stable transform. ▷ Part (I,II) of Theorem 21.11.2
  Compute $A_1 \cdot S_1$, $A_2 \cdot S_2$.
  For each $i \in [2]$, choose T_i to be a sampling and rescaling diagonal matrix according to the Lewis weights of $A_i S_i$, with $t_i = \widetilde{O}(k)$ nonzero entries.
  $C \leftarrow A(T_1, T_2, I)$.
  $B^{i+(j-1)s_1} \leftarrow \mathrm{vec}((T_1 A_1 S_1)_i \otimes (T_2 A_2 S_2)_j), \forall i \in [s_1], j \in [s_2]$.
  Form objective function $\min_W \|WB - C_3\|_1$.
  Run ℓ_p-regression solver to find $\widehat{W}$.
  Construct $\widehat{U}$ by copying $(A_1 S_1)_i$ to the (i,j)-th column of $\widehat{U}$.
  Construct $\widehat{V}$ by copying $(A_2 S_2)_j$ to the (i,j)-th column of $\widehat{V}$.
  return $\widehat{U}, \widehat{V}, \widehat{W}$.
end procedure

As for ℓ_1, notice that if we first apply a sparse Cauchy transform, we can reduce the rank of the matrix to poly(k). Theyn we can apply a dense Cauchy transform and further reduce the dimension, while only incurring another poly(k) factor in the approximation ratio. By combining sparse p-stable and dense p-stable transforms, we can improve the running time from $\mathrm{nnz}(A) \cdot \widetilde{O}(k)$ to be $\mathrm{nnz}(A)$ by losing some additional poly(k) factors in the approximation ratio.

Corollary 21.11.8. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$, $\epsilon \in (0,1)$, let $r = \widetilde{O}(k^2)$. There exists an algorithm which takes $\mathrm{nnz}(A) + n\,\mathrm{poly}(k) + \mathrm{poly}(k)$ time and*

outputs three matrices $U, V, W \in \mathbb{R}^{n \times r}$ *such that*

$$\left\| \sum_{i=1}^{r} U_i \otimes V_i \otimes W_i - A \right\|_p^p \leq \mathrm{poly}(k, \log n) \min_{\mathrm{rank}-k \ A_k} \|A_k - A\|_p^p$$

holds with probability $9/10$.

21.11.6 Algorithms

In this section, we show two different algorithms by using different kind of sketches. One is shown in Theorem 21.11.9 which gives a fast running time. Another one is shown in Theorem 21.11.10 which gives the best approximation ratio.

Theorem 21.11.9. *Given a 3rd tensor $A \in \mathbb{R}^{n\times n\times n}$, for any $k \geq 1$, there exists an algorithm which takes $O(\mathrm{nnz}(A)) + n\,\mathrm{poly}(k) + 2^{\widetilde{O}(k^2)}$ time and outputs three matrices $U, V, W \in \mathbb{R}^{n\times k}$ such that,*

$$\|U \otimes V \otimes W - A\|_p^p \leq \mathrm{poly}(k, \log n) \min_{\mathrm{rank}-k\ A'} \|A' - A\|_p^p.$$

holds with probability at least $9/10$.

Proof. First, we apply part (II) of Theorem 21.11.2. Then $A_i S_i$ can be computed in $O(\mathrm{nnz}(A))$ time. Second, we use Lemma 21.11.4 to reduce the size of the objective function from $O(n^3)$ to $\mathrm{poly}(k)$ in $n\,\mathrm{poly}(k)$ time by only losing a constant factor in approximation ratio. Third, we use Claim 21.3.6 to relax the objective function from entry-wise ℓ_p-norm to Frobenius norm, and this step causes us to lose some other $\mathrm{poly}(k)$ factors in approximation ratio. As a last step, we use Theorem 21.4.44 to solve the Frobenius norm objective function. □

Theorem 21.11.10. *Given a 3rd order tensor $A \in \mathbb{R}^{n\times n\times n}$, for any $k \geq 1$, there exists an algorithm that takes $n^{\widetilde{O}(k)} 2^{\widetilde{O}(k^3)}$ time and output three matrices $U, V, W \in \mathbb{R}^{n\times k}$ such that,*

$$\|U \otimes V \otimes W - A\|_p^p \leq \widetilde{O}(k^{3-1.5p}) \min_{\mathrm{rank}-k\ A'} \|A' - A\|_p^p.$$

holds with probability at least $9/10$.

Proof. First, we apply part (III) of Theorem 21.11.2. Then, guessing S_i requires $n^{\widetilde{O}(k)}$ time. Second, we use Lemma 21.11.4 to reduce the size of the objective from $O(n^3)$ to poly(k) in polynomial time while only losing a constant factor in approximation ratio. Third, we solve the small optimization problem. □

21.11.7 CURT decomposition

Theorem 21.11.11. *Given a 3rd order tensor $A \in \mathbb{R}^{n\times n\times n}$, let $k \geq 1$, and let $U_B, V_B, W_B \in \mathbb{R}^{n\times k}$ denote a rank-k, α-approximation to A. Then there exists an algorithm which takes $O(\mathrm{nnz}(A)) + O(n^2)\,\mathrm{poly}(k)$ time and outputs three matrices $C \in \mathbb{R}^{n\times c}$ with columns from A, $R \in \mathbb{R}^{n\times r}$ with rows from A, $T \in \mathbb{R}^{n\times t}$ with tubes from A, and a tensor $U \in \mathbb{R}^{c\times r\times t}$ with $\mathrm{rank}(U) = k$ such that $c = r = t = O(k \log k \log\log k)$, and*

$$\left\| \sum_{i=1}^{c}\sum_{j=1}^{r}\sum_{l=1}^{t} U_{i,j,l} \cdot C_i \otimes R_j \otimes T_l - A \right\|_p^p \leq \widetilde{O}(k^{3-1.5p})\alpha \min_{\mathrm{rank}-k\ A'} \|A' - A\|_p^p$$

holds with probability $9/10$.

Proof. We define

$$\mathrm{OPT} := \min_{\mathrm{rank}-k\ A'} \|A' - A\|_p^p.$$

We already have three matrices $U_B \in \mathbb{R}^{n\times k}$, $V_B \in \mathbb{R}^{n\times k}$ and $W_B \in \mathbb{R}^{n\times k}$ and these three matrices provide a rank-k, α approximation to A, i.e.,

$$\left\| \sum_{i=1}^{k} (U_B)_i \otimes (V_B)_i \otimes (W_B)_i - A \right\|_p^p \leq \alpha\,\mathrm{OPT}\,. \tag{21.51}$$

Let $B_1 = V_B^\top \odot W_B^\top \in \mathbb{R}^{k\times n^2}$ denote the matrix where the i-th row is the vectorization of $(V_B)_i \otimes (W_B)_i$. By Section B.3 in [SWZ17], we can compute $D_1 \in \mathbb{R}^{n^2\times n^2}$ which is a sampling and rescaling matrix corresponding to the Lewis weights of $B_1^\top$ in $O(n^2\,\mathrm{poly}(k))$ time, and there are $d_1 = O(k \log k \log\log k)$ nonzero entries on the diagonal of D_1. Let $A_i \in \mathbb{R}^{n\times n^2}$ denote the matrix obtained by flattening A along the i-th direction, for each $i \in [3]$.

Define $U^* \in \mathbb{R}^{n\times k}$ to be the optimal solution to $\min_{U\in\mathbb{R}^{n\times k}} \|UB_1 - A_1\|_p^p$, $\widehat{U} = A_1 D_1 (B_1 D_1)^\dagger \in \mathbb{R}^{n\times k}$, $V_0 \in \mathbb{R}^{n\times k}$ to be the optimal solution to $\min_{V\in\mathbb{R}^{n\times k}} \|V \cdot (\widehat{U}^\top \odot W_B^\top) - A_2\|_p^p$, and U' to be the optimal solution to $\min_{U\in\mathbb{R}^{n\times k}} \|UB_1D_1 - A_1D_1\|_p^p$.

By Claim 21.3.4, we have

$$\|\widehat{U}B_1D_1 - A_1D_1\|_p^p \leq d_1^{1-p/2}\|U'B_1D_1 - A_1D_1\|_p^p.$$

Due to Lemma E.11 and Lemma E.8 in [SWZ17], with constant probability, we have

$$\|\widehat{U}B_1 - A_1\|_p^p \leq d_1^{1-p/2}\alpha_{D_1}\|U^*B_1 - A_1\|_p^p, \tag{21.52}$$

where $\alpha_{D_1} = O(1)$.

Recall that $(\widehat{U}^\top \odot W_B^\top) \in \mathbb{R}^{k\times n^2}$ denotes the matrix where the i-th row is the vectorization of $\widehat{U}_i \otimes (W_B)_i$, $\forall i \in [k]$. Now, we can show,

$$\begin{aligned}
\|V_0 \cdot (\widehat{U}^\top \odot W_B^\top) - A_2\|_p^p &\leq \|\widehat{U}B_1 - A_1\|_p^p && \text{by } V_0 = \arg\min_{V\in\mathbb{R}^{n\times k}} \|V \cdot (\widehat{U}^\top \odot W_B^\top) - A_2\|_p^p \\
&\lesssim d_1^{1-p/2}\|U^*B_1 - A_1\|_p^p && \text{by Equation (21.52)} \\
&\leq d_1^{1-p/2}\|U_BB_1 - A_1\|_p^p && \text{by } U^* = \arg\min_{U\in\mathbb{R}^{n\times k}} \|UB_1 - A_1\|_p^p \\
&\leq O(d_1^{1-p/2})\alpha\,\mathrm{OPT}\,. && \text{by Equation (21.51)}
\end{aligned} \tag{21.53}$$

We define $B_2 = \widehat{U}^\top \odot W_B^\top$. We can compute $D_2 \in \mathbb{R}^{n^2\times n^2}$ which is a sampling and rescaling matrix corresponding to the ℓ_p Lewis weights of $B_2^\top$ in $O(n^2\,\mathrm{poly}(k))$ time, and there are $d_2 = O(k\log k\log\log k)$ nonzero entries on the diagonal of D_2.

Define $V^* \in \mathbb{R}^{n\times k}$ to be the optimal solution of $\min_{V\in\mathbb{R}^{n\times k}} \|VB_2 - A_2\|_p^p$, $\widehat{V} = A_2D_2(B_2D_2)^\dagger \in \mathbb{R}^{n\times k}$, $W_0 \in \mathbb{R}^{n\times k}$ to be the optimal solution of $\min_{W\in\mathbb{R}^{n\times k}} \|W\cdot(\widehat{U}^\top \odot \widehat{V}^\top) - A_3\|_p^p$, and V' to be the optimal solution of $\min_{V\in\mathbb{R}^{n\times k}} \|VB_2D_2 - A_2D_2\|_p^p$.

By Claim 21.3.4, we have

$$\|\widehat{V}B_2D_2 - A_2D_2\|_p^p \leq d_2^{1-p/2}\|V'B_2D_2 - A_2D_2\|_p^p.$$

Due to Lemma E.11 and Lemma E.8 in [SWZ17], with constant probability, we have

$$\|\widehat{V}B_2 - A_2\|_p^p \leq d_2^{1-p/2}\alpha_{D_2}\|V^*B_2 - A_2\|_p^p, \tag{21.54}$$

where $\alpha_{D_2} = O(1)$.

Recall that $(\widehat{U}^\top \odot \widehat{V}^\top) \in \mathbb{R}^{k\times n^2}$ denotes the matrix for which the i-th row is the vectorization of $\widehat{U}_i \otimes \widehat{V}_i$, $\forall i \in [k]$. Now, we can show,

$$\begin{aligned}
&\|W_0 \cdot (\widehat{U}^\top \odot \widehat{V}^\top) - A_3\|_p^p \\
\leq\ &\|\widehat{V}B_2 - A_2\|_p^p && \text{by } W_0 = \arg\min_{W\in\mathbb{R}^{n\times k}}\|W \cdot (\widehat{U}^\top \odot \widehat{V}^\top) - A_3\|_p^p \\
\lesssim\ &d_2^{1-p/2}\|V^*B_2 - A_2\|_p^p && \text{by Equation (21.54)} \\
\leq\ &d_2^{1-p/2}\|V_0B_2 - A_2\|_p^p && \text{by } V^* = \arg\min_{V\in\mathbb{R}^{n\times k}}\|VB_2 - A_2\|_p^p \\
\leq\ &O((d_1d_2)^{1-p/2})\alpha\,\mathrm{OPT}\,. && \text{by Equation (21.53)}
\end{aligned} \tag{21.55}$$

We define $B_3 = \widehat{U}^\top \odot \widehat{V}^\top$. We can compute $D_3 \in \mathbb{R}^{n^2\times n^2}$ which is a sampling and rescaling matrix corresponding to the ℓ_p Lewis weights of $B_3^\top$ in $O(n^2\,\mathrm{poly}(k))$ time, and there are $d_3 = O(k\log k\log\log k)$ nonzero entries on the diagonal of D_3.

Define $W^* \in \mathbb{R}^{n\times k}$ to be the optimal solution to $\min_{W\in\mathbb{R}^{n\times k}}\|WB_3 - A_3\|_p^p$, $\widehat{W} = A_3D_3(B_3D_3)^\dagger \in \mathbb{R}^{n\times k}$, and W' to be the optimal solution to $\min_{W\in\mathbb{R}^{n\times k}}\|WB_3D_3 - A_3D_3\|_p^p$.

By Claim 21.3.4, we have

$$\|\widehat{W}B_3D_3 - A_3D_3\|_p^p \leq d_3^{1-p/2}\|W'B_3D_3 - A_3D_3\|_p^p.$$

Due to Lemma E.11 and Lemma E.8 in [SWZ17], with constant probability, we have

$$\|\widehat{W}B_3 - A_3\|_p^p \leq d_3^{1-p/2}\alpha_{D_3}\|W^*B_3 - A_3\|_p^p, \tag{21.56}$$

where $\alpha_{D_3} = O(1)$. Now we can show,

$$\begin{aligned}
\|\widehat{W}B_3 - A_3\|_p^p &\lesssim d_3^{1-p/2}\|W^*B_3 - A_3\|_p^p, && \text{by Equation (21.56)} \\
&\leq d_3^{1-p/2}\|W_0B_3 - A_3\|_p^p, && \text{by } W^* = \arg\min_{W\in\mathbb{R}^{n\times k}}\|WB_3 - A_3\|_p^p \\
&\leq O((d_1d_2d_3)^{1-p/2})\alpha\,\mathrm{OPT}\,. && \text{by Equation (21.55)}
\end{aligned}$$

Thus, it implies,

$$\left\|\sum_{i=1}^{k}\widehat{U}_i\otimes\widehat{V}_i\otimes\widehat{W}_i - A\right\|_p^p \leq \mathrm{poly}(k,\log n)\,\mathrm{OPT}\,.$$

where $\widehat{U} = A_1D_1(B_1D_1)^\dagger$, $\widehat{V} = A_2D_2(B_2D_2)^\dagger$, $\widehat{W} = A_3D_3(B_3D_3)^\dagger$.

□

21.12 Robust Subspace Approximation (Asymmetric Norms for Arbitrary Tensors)

Recently, [CW15b] and [CW15a] study the linear regression problem and low-rank approximation problem under M-Estimator loss functions. In this section, we extend the matrix version of the low rank approximation problem to tensors, i.e., in particular focusing on tensor low-rank approximation under M-Estimator norms. Note that M-Estimators are very different from Frobenius norm and Entry-wise ℓ_1 norm, which are symmetric norms. Namely, flattening the tensor objective function along any of the dimensions does not change the cost if the norm is Frobenius or Entry-wise ℓ_1-norm. However, for M-Estimator norms, we cannot flatten the tensor along all three dimensions. This property makes the tensor low-rank approximation problem under M-Estimator norms more difficult. This section can be split into two independent parts. Section 21.12.2 studies the ℓ_1-ℓ_2-ℓ_2 norm setting, and Section 21.12.3 studies the ℓ_1-ℓ_1-ℓ_2 norm setting.

21.12.1 Preliminaries

Definition 21.12.1 (Nice functions for M-Estimators, $\mathcal{M}_2$, $\mathcal{L}_p$, [CW15a])**.** We say an M-Estimator is **nice** if $M(x) = M(-x)$, $M(0) = 0$, M is non-decreasing in $|x|$, there is a constant $C_M > 0$ and a constant $p \geq 1$ so that for all $a, b \in \mathbb{R}_{>0}$ with $a \geq b$, we have

$$C_m \frac{|a|}{|b|} \leq \frac{M(a)}{M(b)} \leq (\frac{a}{b})^p,$$

and also that $M(x)^{\frac{1}{p}}$ is subadditive, that is, $M(x+y)^{\frac{1}{p}} \leq M(x)^{\frac{1}{p}} + M(y)^{\frac{1}{p}}$.

Let $\mathcal{M}_2$ denote the set of such nice M-estimators, for $p = 2$. Let $\mathcal{L}_p$ denote M-Estimators with $M(x) = |x|^p$ and $p \in [1, 2)$.

21.12.2 ℓ_1-Frobenius (a.k.a ℓ_1-ℓ_2-ℓ_2) norm

Section 21.12.2.1 presents basic definitions and facts for the ℓ_1-ℓ_2-ℓ_2 norm setting. Section 21.12.2.2 introduces some useful tools. Section 21.12.2.3 presents the "no dilation" and "no contraction" bounds, which are the key ideas for reducing the problem to a "generalized" Frobenius norm low rank approximation problem. Finally, we provide our algorithms in Section 21.12.2.6.

21.12.2.1 Definitions

We first give the definition for the v-norm of a tensor, and then give the definition of the v-norm for a matrix and a weighted version of the v-norm for a matrix.

Definition 21.12.2 (Tensor v-norm)**.** For an $n \times n \times n$ tensor A, we define the v-norm of A, denoted $\|A\|_v$, to be

$$\left(\sum_{i=1}^{n} M(\|A_{i,*,*}\|_F) \right)^{1/p},$$

where $A_{i,*,*}$ is the i-th face of A (along the 1st direction), and p is a parameter associated with the function $M()$, which defines a nice M-Estimator.

Definition 21.12.3 (Matrix v-norm)**.** For an $n \times d$ matrix A, we define the v-norm of A, denoted $\|A\|_v$, to be

$$\sum_{i=1}^{n} M(\|A_{i,*}\|_2)^{1/p},$$

where $A_{i,*}$ is the i-th row of A, and p is a parameter associated with the function $M()$, which defines a nice M-Estimator.

Definition 21.12.4. Given matrix $A \in \mathbb{R}^{n\times d}$, let $A_{i,*}$ denote the i-th row of A. Let $T_S \subset [n]$ denote the indices i such that e_i is chosen for S. Using a probability vector q and a sampling and rescaling matrix $S \in \mathbb{R}^{n\times n}$ from q, we will estimate $\|A\|_v$ using S and a re-weighted version, $\|S\cdot\|_{v,w'}$ of $\|\cdot\|_v$, with

$$\|SA\|_{v,w'} = \left(\sum_{i\in T_S} w_i' M(\|A_{i,*}\|_2)\right)^{1/p},$$

where $w_i' = w_i/q_i$. Since w' is generally understood, we will usually just write $\|SA\|_v$. We will also need an "entrywise row-weighted" version :

$$|||SA||| = \left(\sum_{i\in T_S} \frac{w_i}{q_i}\|A_{i,*}\|_M^p\right)^{1/p} = \left(\sum_{i\in T_S, j\in[d]} \frac{w_i}{q_i} M(A_{i,j})\right)^{1/p},$$

where $A_{i,j}$ denotes the entry in the i-th row and j-th column of A.

Fact 21.12.1. *For $p = 1$, for any two matrices A and B, we have $\|A+B\|_v \le \|A\|_v + \|B\|_v$. For any two tensors A and B, we have $\|A+B\|_v \le \|A\|_v + \|B\|_v$.*

21.12.2.2 Sampling and rescaling sketches

Note that Lemmas 42 and 44 in [CW15a] are stronger than stated. In particular, we do not need to assume X is a square matrix. For any $m \ge z$, if $X \in \mathbb{R}^{d\times m}$, then we have the same result.

Lemma 21.12.2 (Lemma 42 in [CW15a])**.** *Let $\rho > 0$ and integer $z > 0$. For sampling matrix S, suppose for a given $y \in \mathbb{R}^d$ with failure probability δ it holds that $\|SAy\|_M = (1\pm 1/10)\|Ay\|_M$. There is $K_1 = O(z^2/C_M)$ so that with failure probability $\delta(K_N/C_M)^{(1+p)d}$, for a constant K_N, any rank-z matrix $X \in \mathbb{R}^{d\times m}$ has the property that if $\|AX\|_v \ge K_1\rho$, then $\|SAX\|_v \ge \rho$, and that if $\|AX\|_v \le \rho/K_1$, then $\|SAX\|_v \le \rho$.*

Lemma 21.12.3 (Lemma 44 in [CW15a]). *Let $\delta, \rho > 0$ and integer $z > 0$. Given matrix $A \in \mathbb{R}^{n\times d}$, there exists a sampling and rescaling matrix $S \in \mathbb{R}^{n\times n}$ with $r = O(\gamma(A, M, w)\epsilon^{-2}dz^2 \log(z/\epsilon)\log(1/\delta))$ nonzero entries such that, with probability at least $1-\delta$, for any* rank-z *matrix $X \in \mathbb{R}^{d\times m}$, we have either*

$$\|SAX\|_v \geq \rho,$$

or

$$(1-\epsilon)\|AX\|_v - \epsilon\rho \leq \|SAX\|_v \leq (1+\epsilon)\|AX\|_v + \epsilon\rho.$$

Lemma 21.12.4 (Lemma 43 in [CW15a]). *For $r > 0$, let $\widehat{r} = r/\gamma(A, M, w)$, and let $q \in \mathbb{R}^n$ have*

$$q_i = \min\{1, \widehat{r}\gamma_i(A, M, w)\}.$$

Let S be a sampling and rescaling matrix generated using q, with weights as usual $w_i' = w_i/q_i$. Let $W \in \mathbb{R}^{d\times z}$, and $\delta > 0$. There is an absolute constant C so that for $\widehat{r} \geq Cz\log(1/\delta)/\epsilon^2$, with probability at least $1-\delta$, we have

$$(1-\epsilon)\|AW\|_{v,w} \leq \|SAW\|_{v,w'} \leq (1+\epsilon)\|AW\|_{v,w}.$$

21.12.2.3 No dilation and no contraction

Lemma 21.12.5. *Given matrices $A \in \mathbb{R}^{n\times m}$, $U \in \mathbb{R}^{n\times d}$, let $V^* = \underset{\text{rank}-k\ V\in\mathbb{R}^{d\times m}}{\arg\min} \|UV - A\|_v$. If $S \in \mathbb{R}^{s\times n}$ has at most c_1-dilation on $UV^* - A$, i.e.,*

$$\|S(UV^* - A)\|_v \leq c_1\|UV^* - A\|_v,$$

and it has at most c_2-contraction on U, i.e.,

$$\forall x \in \mathbb{R}^d, \|SUx\|_v \geq \frac{1}{c_2}\|Ux\|_v,$$

then S has at most $(c_2, c_1 + \frac{1}{c_2})$-contraction on (U, A), i.e.,

$$\forall \text{ rank}-k\ V \in \mathbb{R}^{d\times m}, \|SUV - SA\|_v \geq \frac{1}{c_2}\|UV - A\|_v - (c_1 + \frac{1}{c_2})\|UV^* - A\|_v.$$

Proof. Let $A \in \mathbb{R}^{n\times m}$, $U \in \mathbb{R}^{n\times d}$ and $S \in \mathbb{R}^{s\times n}$ be the same as that described in the lemma. Let $(V - V^*)_j$ denote the j-th column of $V - V^*$. Then $\forall$ rank $-k$ $V \in \mathbb{R}^{d\times m}$,

$$\begin{aligned}
\|SUV - SA\|_v &\geq \|SUV - SUV^*\|_v - \|SUV^* - SA\|_v \\
&\geq \|SUV - SUV^*\|_v - c_1\|UV^* - A\|_v \\
&= \|SU(V - V^*)\|_v - c_1\|UV^* - A\|_v \\
&= \sum_{j=1}^{m} \|SU(V - V^*)_j\|_v - c_1\|UV^* - A\|_v \\
&\geq \sum_{j=1}^{m} \frac{1}{c_2}\|U(V - V^*)_j\|_v - c_1\|UV^* - A\|_v \\
&= \frac{1}{c_2}\|UV - UV^*\|_v - c_1\|UV^* - A\|_v \\
&\geq \frac{1}{c_2}\|UV - A\|_v - \frac{1}{c_2}\|UV^* - A\|_v - c_1\|UV^* - A\|_v \\
&= \frac{1}{c_2}\|UV - A\|_v - \left((\frac{1}{c_2} + c_2)\|UV^* - A\|_v\right),
\end{aligned}$$

where the first inequality follows by the triangle inequality, the second inequality follows since S has at most c_1 dilation on $UV^* - A$, the third inequality follows since S has at most c_2 contraction on U, and the fourth inequality follows by the triangle inequality. □

Claim 21.12.6. *Given matrix $A \in \mathbb{R}^{n\times m}$, for any distribution $p = (p_1, p_2, \cdots, p_n)$ define random variable X such that $X = \|A_i\|_2/p_i$ with probability p_i where A_i is the i-th row of matrix A. Then take m independent samples $X^1, X^2, \cdots, X^m$, and let $Y = \frac{1}{m}\sum_{j=1}^m X^j$. We have*

$$\Pr[Y \leq 1000\|A\|_v] \geq .999.$$

Proof. We can compute the expectation of X^j, for any $j \in [m]$,

$$\mathbb{E}[X^j] = \sum_{i=1}^n \frac{\|A_i\|_2}{p_i} \cdot p_i = \|A\|_v.$$

Then $\mathbb{E}[Y] = \frac{1}{m}\sum_{j=1}^m \mathbb{E}[X^j] = \|A\|_v$. Using Markov's inequality, we have

$$\Pr[Y \geq \|A\|_v] \leq .001.$$

□

Lemma 21.12.7. *For any fixed $U^* \in \mathbb{R}^{n\times d}$ and* rank-k *$V^* \in \mathbb{R}^{d\times m}$ with $d = \mathrm{poly}(k)$, there exists an algorithm that takes $\mathrm{poly}(n, d)$ time to compute a sampling and rescaling diagonal matrix $S \in \mathbb{R}^{n\times n}$ with $s = \mathrm{poly}(k)$ nonzero entries such that, with probability at least .999, we have: for all* rank-k *$V \in \mathbb{R}^{d\times m}$,*

$$\|U^*V^* - U^*V\|_v \lesssim \|SU^*V^* - SU^*V\|_v \lesssim \|U^*V^* - U^*V\|_v.$$

Lemma 21.12.8 (No dilation)**.** *Given matrices $A \in \mathbb{R}^{n\times m}$, $U^* \in \mathbb{R}^{n\times d}$ with $d = \mathrm{poly}(k)$, define $V^* \in \mathbb{R}^{d\times m}$ to be the optimal solution $\min_{\mathrm{rank}-k\ V\in\mathbb{R}^{d\times m}} \|U^*V - A\|_v$. Choose a sampling and rescaling diagonal matrix $S \in \mathbb{R}^{n\times n}$ with $s = \mathrm{poly}(k)$ according to Lemma 21.12.4. Then with probability at least .99, we have: for all* rank-k *$V \in \mathbb{R}^{d\times m}$,*

$$\|SU^*V - SA\|_v \lesssim \|U^*V^* - U^*V\|_v + O(1)\|U^*V^* - A\|_v \lesssim \|U^*V - A\|_v.$$

Proof. Using Claim 21.12.6 and Lemma 21.12.7, we have with probability at least .99, for all rank-k $V \in \mathbb{R}^{d\times m}$,

$$\begin{aligned}
&\|SU^*V - SA\|_v \\
\leq\ &\|SU^*V - SU^*V^*\|_v + \|SU^*V^* - SA\|_v && \text{by triangle inequality} \\
\lesssim\ &\|SU^*V - SU^*V^*\|_v + O(1)\|U^*V^* - A\|_v && \text{by Claim 21.12.6} \\
\lesssim\ &\|U^*V - U^*V^*\|_v + O(1)\|U^*V^* - A\|_v && \text{by Lemma 21.12.7} \\
\lesssim\ &\|U^*V - A\|_v + \|U^*V^* - A\|_v + O(1)\|U^*V^* - A\|_v && \text{by triangle inequality} \\
\lesssim\ &\|U^*V - A\|_v.
\end{aligned}$$

□

Lemma 21.12.9 (No contraction)**.** *Given matrices $A \in \mathbb{R}^{n\times m}$, $U^* \in \mathbb{R}^{n\times d}$ with $d = \mathrm{poly}(k)$, define $V^* \in \mathbb{R}^{d\times m}$ to be the optimal solution $\min_{\mathrm{rank}-k\ V\in\mathbb{R}^{d\times m}} \|U^*V - A\|_v$. Choose a sampling and rescaling diagonal matrix $S \in \mathbb{R}^{n\times n}$ with $s = \mathrm{poly}(k)$ according to Lemma 21.12.4. Then with probability at least .99, we have: for all* rank-k $V \in \mathbb{R}^{d\times m}$,

$$\|U^*V - A\|_v \lesssim \|SU^*V - SA\|_v + O(1)\|U^*V^* - A\|_v.$$

Proof. This follows by Lemma 21.12.5, Claim 21.12.6 and Lemma 21.12.8. □

21.12.2.4 Oblivious sketches, MSketch

In this section, we recall a concept called M-sketches for M-estimators which is defined in [CW15b]. M-sketch is an oblivious sketch for matrices.

Theorem 21.12.10 (Theorem 3.1 in [CW15b]). *Let* OPT *denote* $\min_{x\in\mathbb{R}^d}\|Ax-b\|_G$. *There is an algorithm that in* $O(\mathrm{nnz}(A))+\mathrm{poly}(d\log n)$ *time, with constant probability finds* x' *such that* $\|Ax'-b\|_G \leq O(1)\,\mathrm{OPT}$.

Definition 21.12.5 (M-Estimator sketches or MSketch [CW15b]). Given parameters $N, n, m, b > 1$, define $h_{\max} = \lfloor \log_b(n/m) \rfloor$, $\beta = (b - b^{-h_{\max}})/(b-1)$ and $s = Nh_{\max}$. For each $p \in [n]$, σ_p, g_p, h_p are generated (independently) in the following way,

$$\begin{aligned} &\sigma_p \leftarrow \pm 1, && \text{chosen with equal probability,} \\ &g_p \in [N], && \text{chosen with equal probability,} \\ &h_p \leftarrow t, && \text{chosen with probability } 1/(\beta b^t) \text{ for } t \in \{0, 1, \cdots h_{\max}\}. \end{aligned}$$

For each $p \in [n]$, we define $j_p = g_p + Nh_p$. Let $w \in \mathbb{R}^s$ denote the scaling vector such that, for each $j \in [s]$,

$$w_j = \begin{cases} \beta b^{h_p}, & \text{if there exists } p \in [n] \text{ s.t.} j = j_p, \\ 0 & \text{otherwise.} \end{cases}$$

Let $\overline{S} \in \mathbb{R}^{Nh_{\max} \times n}$ be such that, for each $j \in [s]$,for each $p \in [n]$,

$$\overline{S}_{j,p} = \begin{cases} \sigma_p, & \text{if } j = g_p + N \cdot h_p, \\ 0, & \text{otherwise.} \end{cases}$$

Let D_w denote the diagonal matrix where the i-th entry on the diagonal is the i-th entry of w. Let $S = D_w\overline{S}$. We say $(\overline{S}, w)$ or S is an MSketch.

Definition 21.12.6 (Tensor $\|\|\|_{v,w}$-norm). For a tensor $A \in \mathbb{R}^{d\times n_1\times n_2}$ and a vector $w \in$, we define

$$\|A\|_{v,w} = \sum_{i=1}^{d} w_i \|A_{i,*,*}\|_F.$$

Let $(\overline{S}, w)$ denote an MSketch, and let $S = D_w \overline{S}$. If v corresponds to a scale-invariant M-Estimator, then for any three matrices U, V, W, we have the following,

$$\|(\overline{S}U) \otimes V \otimes W\|_{v,w} = \|(D_w \overline{S}U) \otimes V \otimes W\|_v = \|(SU) \otimes V \otimes W\|_v.$$

Fact 21.12.11. *For a tensor $A \in \mathbb{R}^{n \times n \times n}$, let $S \in \mathbb{R}^{s \times n}$ denote an* MSketch *(defined in 21.12.5) with $s = \mathrm{poly}(k, \log n)$. Then SA can be computed in $O(\mathrm{nnz}(A))$ time.*

Lemma 21.12.12. *For any fixed $U^* \in \mathbb{R}^{n \times d}$ and* rank-k *$V^* \in \mathbb{R}^{d \times m}$ with $d = \mathrm{poly}(k)$, let $S \in \mathbb{R}^{s \times n}$ denote an* MSketch *(defined in Definition 21.12.5) with $s = \mathrm{poly}(k, \log n)$ rows. Then with probability at least .999, we have: for all* rank-k *$V \in \mathbb{R}^{d \times m}$,*

$$\|U^*V^* - U^*V\|_v \lesssim \|SU^*V^* - SU^*V\|_v \lesssim \|U^*V^* - U^*V\|_v.$$

Lemma 21.12.13 (No dilation, Theorem 3.4 in [CW15b])**.** *Given matrices $A \in \mathbb{R}^{n \times m}$, $U^* \in \mathbb{R}^{n \times d}$ with $d = \mathrm{poly}(k)$, define $V^* \in \mathbb{R}^{d \times m}$ to be the optimal solution to $\min_{\mathrm{rank}-k \ V \in \mathbb{R}^{d \times m}} \|U^*V - A\|_v$. Choose an* MSketch *$S \in \mathbb{R}^{s \times n}$ with $s = \mathrm{poly}(k, \log n)$ according to Definition 21.12.5. Then with probability at least .99, we have: for all* rank-k *$V \in \mathbb{R}^{d \times m}$,*

$$\|SU^*V - SA\|_v \lesssim \|U^*V^* - U^*V\|_v + O(1)\|U^*V^* - A\|_v \lesssim \|U^*V - A\|_v.$$

Lemma 21.12.14 (No contraction)**.** *Given matrices $A \in \mathbb{R}^{n \times m}$, $U^* \in \mathbb{R}^{n \times d}$ with $d = \mathrm{poly}(k)$, define $V^* \in \mathbb{R}^{d \times m}$ to be the optimal solution to $\min_{\mathrm{rank}-k \ V \in \mathbb{R}^{d \times m}} \|U^*V - A\|_v$. Choose an* MSketch *$S \in \mathbb{R}^{s \times n}$ with $s = \mathrm{poly}(k, \log n)$ according to Definition 21.12.5. Then with probability at least .99, we have: for all* rank-k *$V \in \mathbb{R}^{d \times m}$,*

$$\|U^*V - A\|_v \lesssim \|SU^*V - SA\|_v + O(1)\|U^*V^* - A\|_v.$$

21.12.2.5 Running time analysis

Lemma 21.12.15. *Given a tensor $A \in \mathbb{R}^{n\times d\times d}$, let $S \in \mathbb{R}^{s\times n}$ denote an* MSketch *with s rows. Let SA denote a tensor that has size $s \times d \times d$. For each $i \in \{2, 3\}$, let $(SA)_i \in \mathbb{R}^{d\times ds}$ denote a matrix obtained by flattening tensor SA along the i-th dimension. For each $i \in \{2, 3\}$, let $S_i \in \mathbb{R}^{ds\times s_i}$ denote a CountSketch transform with s_i columns. For each $i \in \{2, 3\}$, let $T_i \in \mathbb{R}^{t_i\times d}$ denote a CountSketch transform with t_i rows. Then*

(I) *For each $i \in \{2, 3\}$, $(SA)_i S_i$ can be computed in $O(\mathrm{nnz}(A))$ time.*

(II) *For each $i \in \{2, 3\}$, $T_i(SA)_i S_i$ can be computed in $O(\mathrm{nnz}(A))$ time.*

Proof. Proof of Part (I). First note that $(SA)_2 S_2$ has size $n\times S_2$. Thus for each $i \in [d], j \in [s_2]$, we have,

$$\begin{aligned}
((SA)_2 S_2)_{i,j} &= \sum_{x'=1}^{ds} ((SA)_2)_{i,x'} (S_2)_{x',j} && \text{by } (SA)_2 \in \mathbb{R}^{d\times ds}, S_2 \in \mathbb{R}^{ds\times s_2} \\
&= \sum_{y=1}^{d}\sum_{z=1}^{s} ((SA)_2)_{i,(y-1)s+z} (S_2)_{(y-1)s+z,j} \\
&= \sum_{y=1}^{d}\sum_{z=1}^{s} (SA)_{z,i,y} (S_2)_{(y-1)s+z,j} && \text{by unflattening} \\
&= \sum_{y=1}^{d}\sum_{z=1}^{s} \left(\sum_{x=1}^{n} S_{z,x} A_{x,i,y}\right) (S_2)_{(y-1)s+z,j} \\
&= \sum_{y=1}^{d}\sum_{z=1}^{s}\sum_{x=1}^{n} S_{z,x} \cdot A_{x,i,y} \cdot (S_2)_{(y-1)s+z,j}.
\end{aligned}$$

For each nonzero entry $A_{x,i,y}$, there is only one z such that $S_{z,x}$ is nonzero. Thus there is only one j such that $(S_2)_{(y-1)s+z,j}$ is nonzero. It means that $A_{x,i,y}$ can only affect one entry of $((SA)_2 S_2)_{i,j}$. Thus, $(SA)_2 S_2$ can be computed in $O(\mathrm{nnz}(A))$ time. Similarly, we can compute $(SA)_3 S_3$ in $O(\mathrm{nnz}(A))$ time.

Proof of Part (II). Note that $T_2(SA)_2S_2$ has size $t_2 \times s_2$. Thus for each $i \in [t_2], j \in [s_2]$, we have,

$$\begin{aligned}
(T_2(SA)_2S_2)_{i,j} &= \sum_{x=1}^{d}\sum_{y'=1}^{ds}(T_2)_{i,x}((SA)_2)_{x,y'}(S_2)_{y',j} && \text{by } (SA)_2 \in \mathbb{R}^{d\times ds} \\
&= \sum_{x=1}^{d}\sum_{y=1}^{d}\sum_{z=1}^{s}(T_2)_{i,x}((SA)_2)_{x,(y-1)s+z}(S_2)_{(y-1)s+z,j} \\
&= \sum_{x=1}^{d}\sum_{y=1}^{d}\sum_{z=1}^{s}(T_2)_{i,x}(SA)_{z,x,y}(S_2)_{(y-1)s+z,j} && \text{by unflattening} \\
&= \sum_{x=1}^{d}\sum_{y=1}^{d}\sum_{z=1}^{s}(T_2)_{i,x}\left(\sum_{w=1}^{n}S_{z,w}A_{w,x,y}\right)(S_2)_{(y-1)s+z,j} \\
&= \sum_{x=1}^{d}\sum_{y=1}^{d}\sum_{z=1}^{s}\sum_{w=1}^{n}(T_2)_{i,x}\cdot S_{z,w}\cdot A_{w,x,y}\cdot(S_2)_{(y-1)s+z,j}.
\end{aligned}$$

For each nonzero entry $A_{w,x,y}$, there is only one z such that $S_{z,w}$ is nonzero. There is only one i such that $(T_2)_{i,x}$ is nonzero. Since there is only one z to make $S_{z,w}$ nonzero, there is only one j, such that $(S_2)_{(y-1)s+z,j}$ is nonzero. Thus, $T_2(SA)_2S_2$ can be computed in $O(\text{nnz}(A))$ time. Similarly, we can compute $T_3(SA)_3S_3$ in $O(\text{nnz}(A))$ time. □

21.12.2.6 Algorithms

We first give a "warm-up" algorithm in Theorem 21.12.16 by using a sampling and rescaling matrix. Then we improve the running time to be polynomial in all the parameters by using an oblivious sketch, and thus we obtain Theorem 21.12.17.

Theorem 21.12.16. *Given a 3rd order tensor $A \in \mathbb{R}^{n\times n\times n}$, for any $k \geq 1$, let $r = O(k^2)$. There exists an algorithm which takes $n^{\text{poly}(k)}$ time and outputs three matrices $U, V, W \in \mathbb{R}^{n\times r}$*

Algorithm 21.36 ℓ_1-Frobenius(ℓ_1-ℓ_2-ℓ_2) Low-rank Approximation Algorithm, poly(k) approximation

procedure L122TensorLowRankApprox(A, n, k) ▷ Theorem 21.12.16
  $\epsilon \leftarrow 0.1$.
  $s \leftarrow \text{poly}(k, 1/\epsilon)$.
  Guess a sampling and rescaling matrix $S \in \mathbb{R}^{s \times n}$.
  $s_2 \leftarrow s_3 \leftarrow O(k/\epsilon)$.
  $r \leftarrow s_2 s_3$.
  Choose sketching matrices $S_2 \in \mathbb{R}^{ns \times s_2}$, $S_3 \in \mathbb{R}^{ns \times s_3}$.
  Compute $(SA)_2 S_2, (SA)_3 S_3$.
  Form $\widetilde{V} \in \mathbb{R}^{n \times r}$ by repeating $(SA)_2 S_2$ s_3 times according to Equation (21.64).
  Form $\widetilde{W} \in \mathbb{R}^{n \times r}$ by repeating $(SA)_3 S_3$ s_2 times according to Equation (21.65).
  Form objective function $\min_{U \in \mathbb{R}^{n \times r}} \|U \cdot (\widetilde{V}^\top \odot \widetilde{W}^\top) - A_1\|_F$.
  Use a linear regression solver to find a solution $\widetilde{U}$.
  Take the best solution found over all guesses.
  return $\widetilde{U}$, $\widetilde{V}$, $\widetilde{W}$.
end procedure

such that

$$\|U \otimes V \otimes W - A\|_v \leq \text{poly}(k) \min_{\text{rank}-k\ A'} \|A' - A\|_v,$$

holds with probability at least $9/10$.

Proof. We define OPT as follows,

$$\text{OPT} = \min_{U,V,W \in \mathbb{R}^{n \times k}} \|U \otimes V \otimes W - A\|_v = \min_{U,V,W \in \mathbb{R}^{n \times k}} \left\| \sum_{i=1}^k U_i \otimes V_i \otimes W_i - A \right\|_v.$$

Let $A_1 \in \mathbb{R}^{n \times n^2}$ denote the matrix obtained by flattening tensor A along the 1st dimension. Let $U^* \in \mathbb{R}^{n \times k}$ denote the optimal solution. We fix $U^* \in \mathbb{R}^{n \times k}$, and consider this objective function,

$$\min_{V,W \in \mathbb{R}^{n \times k}} \|U^* \otimes V \otimes W - A\|_v \equiv \min_{V,W \in \mathbb{R}^{n \times k}} \left\|U^* \cdot (V^\top \odot W^\top) - A_1\right\|_v, \tag{21.57}$$

which has cost at most OPT, and where $V^\top \odot W^\top \in \mathbb{R}^{k\times n^2}$ denotes the matrix for which the i-th row is a vectorization of $V_i \otimes W_i, \forall i \in [k]$. (Note that $V_i \in \mathbb{R}^n$ is the i-th column of matrix $V \in \mathbb{R}^{n\times k}$). Choose a sampling and rescaling diagonal matrix $S \in \mathbb{R}^{n\times n}$ according to U^*, which has $s = \text{poly}(k)$ non-zero entries. Using S to sketch on the left of the objective function when U^* is fixed (Equation (21.57)), we obtain a smaller problem,

$$\min_{V,W\in\mathbb{R}^{n\times k}} \|(SU^*)\otimes V\otimes W - SA\|_v \equiv \min_{V,W\in\mathbb{R}^{n\times k}} \left\|SU^*\cdot(V^\top \odot W^\top) - SA_1\right\|_v . \tag{21.58}$$

Let V', W' denote the optimal solution to the above problem, i.e.,

$$V', W' = \arg\min_{V,W\in\mathbb{R}^{n\times k}} \|(SU^*)\otimes V\otimes W - SA\|_v .$$

Then using properties (no dilation Lemma 21.12.8 and no contraction Lemma 21.12.9) of S, we have

$$\|U^*\otimes V'\otimes W' - A\|_v \le \alpha\,\text{OPT}\,.$$

where α is an approximation ratio determined by S.

By definition of $\|\cdot\|_v$ and $\|\cdot\|_2 \le \|\cdot\|_1 \le \sqrt{\dim}\|\cdot\|_2$, we can rewrite Equation (21.58) in the following way,

$$\begin{aligned}
&\|(SU^*)\otimes V\otimes W - SA\|_v \\
&= \sum_{i=1}^{s}\left(\sum_{j=1}^{n}\sum_{l=1}^{n}\left(((SU^*)\otimes V\otimes W)_{i,j,l} - (SA)_{i,j,l}\right)^2\right)^{\frac{1}{2}} \\
&\le \sqrt{s}\left(\sum_{i=1}^{s}\sum_{j=1}^{n}\sum_{l=1}^{n}\left(((SU^*)\otimes V\otimes W)_{i,j,l} - (SA)_{i,j,l}\right)^2\right)^{\frac{1}{2}} \\
&= \sqrt{s}\,\|(SU^*)\otimes V\otimes W - SA\|_F\,.
\end{aligned} \tag{21.59}$$

Given the above properties of S and Equation (21.59), for any $\beta \geq 1$, let V'', W'' denote a β-approximate solution of $\min_{V,W \in \mathbb{R}^{n \times k}} \|(SU^*) \otimes V \otimes W - SA\|_F$, i.e.,

$$\|(SU^*) \otimes V'' \otimes W'' - SA\|_F \leq \beta \cdot \min_{V,W \in \mathbb{R}^{n \times k}} \|(SU^*) \otimes V \otimes W - SA\|_F . \tag{21.60}$$

Then,

$$\|U^* \otimes V'' \otimes W'' - A\|_v \leq \sqrt{s}\alpha\beta \cdot \mathrm{OPT} . \tag{21.61}$$

In the next few paragraphs we will focus on solving Equation (21.60). We start by fixing $W^* \in \mathbb{R}^{n \times k}$ to be the optimal solution of

$$\min_{V,W \in \mathbb{R}^{n \times k}} \|(SU^*) \otimes V \otimes W - SA\|_F .$$

We use $(SA)_2 \in \mathbb{R}^{n \times ns}$ to denote the matrix obtained by flattening the tensor $SA \in \mathbb{R}^{s \times n \times n}$ along the second direction. We use $Z_2 = (SU^*)^\top \odot (W^*)^\top \in \mathbb{R}^{k \times ns}$ to denote the matrix where the i-th row is the vectorization of $(SU^*)_i \otimes W_i^*$. We can consider the following objective function,

$$\min_{V \in \mathbb{R}^{n \times k}} \|VZ_2 - (SA)_2\|_F .$$

Choosing a sketching matrix $S_2 \in \mathbb{R}^{ns \times s_2}$ with $s_2 = O(k/\epsilon)$ gives a smaller problem,

$$\min_{V \in \mathbb{R}^{n \times k}} \|VZ_2S_2 - (SA)_2S_2\|_F .$$

Letting $\widehat{V} = (SA)_2 S_2 (Z_2 S_2)^\dagger \in \mathbb{R}^{n\times k}$, then

$$\begin{aligned}
\|\widehat{V} Z_2 - (SA)_2\|_F &\leq (1+\epsilon) \min_{V\in\mathbb{R}^{n\times k}} \|V Z_2 - (SA)_2\|_F \\
&= (1+\epsilon) \min_{V\in\mathbb{R}^{n\times k}} \|V((SU^*)^\top \odot (W^*)^\top) - (SA)_2\|_F \\
&= (1+\epsilon) \min_{V\in\mathbb{R}^{n\times k}} \|(SU^*)\otimes V \otimes W^* - SA\|_F \qquad \text{by unflattening} \\
&= (1+\epsilon) \min_{V,W\in\mathbb{R}^{n\times k}} \|(SU^*)\otimes V \otimes W - SA\|_F. \qquad \text{by definition of } W^*
\end{aligned} \tag{21.62}$$

We define $D_2 \in \mathbb{R}^{n^2\times n^2}$ to be a diagonal matrix obrained by copying the $n\times n$ identity matrix s times on n diagonal blocks of D_2. Then it has ns nonzero entries. Thus, D_2 also can be thought of as a matrix that has size $n^2 \times ns$.

We can think of $(SA)_2 S_2 \in \mathbb{R}^{n\times s_2}$ as follows,

$$\begin{aligned}
(SA)_2 S_2 &= (A(S,I,I))_2 S_2 \\
&= \underbrace{A_2}_{n\times n^2} \cdot \underbrace{D_2}_{n^2\times n^2} \cdot \underbrace{S_2}_{ns\times s_2} \text{ by } D_2 \text{ can be thought of as having size } n^2\times ns \\
&= A_2 \cdot \begin{bmatrix} c_{2,1} I_n & & & \\ & c_{2,2} I_n & & \\ & & \ddots & \\ & & & c_{2,n} I_n \end{bmatrix} \cdot S_2
\end{aligned}$$

where I_n is an $n\times n$ identity matrix, $c_{2,i} \geq 0$ for each $i \in [n]$, and the number of nonzero $c_{2,i}$ is s.

For the last step, we fix SU^* and $\widehat{V}$. We use $(SA)_3 \in \mathbb{R}^{n\times ns}$ to denote the matrix obtained by flattening the tensor $SA \in \mathbb{R}^{s\times n\times n}$ along the third direction. We use $Z_3 = (SU^*)^\top \odot \widehat{V}^\top \in \mathbb{R}^{k\times ns}$ to denote the matrix where the i-th row is the vectorization of

$(SU^*)_i \otimes \widehat{V}_i$. We can consider the following objective function,

$$\min_{W \in \mathbb{R}^{n \times k}} \|WZ_3 - (SA)_3\|_F.$$

Choosing a sketching matrix $S_3 \in \mathbb{R}^{ns \times s_3}$ with $s_3 = O(k/\epsilon)$ gives a smaller problem,

$$\min_{W \in \mathbb{R}^{n \times k}} \|WZ_3S_3 - (SA)_3S_3\|_F.$$

Let $\widehat{W} = (SA)_3S_3(Z_3S_3)^\dagger \in \mathbb{R}^{n \times k}$. Then

$$\begin{aligned}
\|\widehat{W}Z_3 - (SA)_3\|_F &\leq (1+\epsilon) \min_{W \in \mathbb{R}^{n \times k}} \|WZ_3 - (SA)_3\|_F && \text{by property of } S_3 \\
&= (1+\epsilon) \min_{W \in \mathbb{R}^{n \times k}} \|W((SU^*)^\top \odot \widehat{V}^\top) - (SA)_3\|_F && \text{by definition } Z_3 \\
&= (1+\epsilon) \min_{W \in \mathbb{R}^{n \times k}} \|(SU^*) \otimes \widehat{V} \otimes W - SA\|_F && \text{by unflattening} \\
&\leq (1+\epsilon)^2 \|(SU^*) \otimes V \otimes W - SA\|_F . && \text{by Equation (21.62)}
\end{aligned}$$

We define $D_3 \in \mathbb{R}^{n^2 \times n^2}$ to be a diagonal matrix formed by copying the $n \times n$ identity matrix s times on n diagonal blocks of D_3. Then it has ns nonzero entries. Thus, D_3 also can be thought of as a matrix that has size $n^2 \times ns$ and D_3 is uniquely determined by S.

Similarly as to the 2nd dimension, for the 3rd dimension, we can think of $(SA)_3S_3$ as follows,

$$\begin{aligned}
(SA)_3S_3 &= (A(S, I, I))_3S_3 \\
&= \underbrace{A_3}_{n \times n^2} \cdot \underbrace{D_3}_{n^2 \times n^2} \cdot \underbrace{S_3}_{ns \times s_3} && \text{by } D_3 \text{ can be thought of as having size } n^2 \times ns \\
&= A_3 \cdot \begin{bmatrix} c_{3,1}I_n & & & \\ & c_{3,2}I_n & & \\ & & \ddots & \\ & & & c_{3,n}I_n \end{bmatrix} \cdot S_3
\end{aligned}$$

where I_n is an $n \times n$ identity matrix, $c_{3,i} \geq 0$ for each $i \in [n]$ and the number of nonzero $c_{3,i}$ is s.

Overall, we have proved that,

$$\min_{X_2, X_3} \|(SU^*) \otimes (A_2 D_2 S_2 X_2) \otimes (A_3 D_3 S_3 X_3) - SA\|_F \leq (1+\epsilon)^2 \|(SU^*) \otimes V \otimes W - SA\|_F , \tag{21.63}$$

where diagonal matrix $D_2 \in \mathbb{R}^{n^2 \times n^2}$ (with ns nonzero entries) and $D_3 \in \mathbb{R}^{n^2 \times n^2}$ (with ns nonzero entries) are uniquely determined by diagonal matrix $S \in \mathbb{R}^{n \times n}$ (s nonzero entries). Let X_2' and X_3' denote the optimal solution to the above problem (Equation (21.63)). Let $V'' = (A_2 D_2 S_2 X_2') \in \mathbb{R}^{n \times k}$ and $W'' = (A_3 D_3 S_3 X_3') \in \mathbb{R}^{n \times k}$. Then we have

$$\|U^* \otimes V'' \otimes W'' - A\|_v \leq \sqrt{s}\alpha\beta \, \mathrm{OPT} .$$

We construct matrix $\widetilde{V} \in \mathbb{R}^{n \times s_2 s_3}$ by copying matrix $(SA)_2 S_2 \in \mathbb{R}^{n \times s_2}$ s_3 times,

$$\widetilde{V} = \begin{bmatrix} (SA)_2 S_2 & (SA)_2 S_2 & \cdots & (SA)_2 S_2 . \end{bmatrix} \tag{21.64}$$

We construct matrix $\widetilde{W} \in \mathbb{R}^{n \times s_2 s_3}$ by copying the i-th column of matrix $(SA)_3 S_3 \in \mathbb{R}^{n \times s_3}$ into $(i-1)s_2 + 1, \cdots, is_2$ columns of $\widetilde{W}$,

$$\widetilde{W} = \begin{bmatrix} ((SA)_3 S_3)_1 \cdots ((SA)_3 S_3)_1 & ((SA)_3 S_3)_2 \cdots ((SA)_3 S_3)_2 & \cdots & ((SA)_3 S_3)_{s_3} \cdots ((SA)_3 S_3)_{s_3} . \end{bmatrix} \tag{21.65}$$

Although we don't know S, we can guess all of the possibilities. For each possibility,

we can find a solution $\widetilde{U} \in \mathbb{R}^{n \times s_2 s_3}$ to the following problem,

$$\begin{aligned}
& \min_{U \in \mathbb{R}^{n \times s_2 s_3}} \left\| \sum_{i=1}^{s_2} \sum_{j=1}^{s_3} U_{(i-1)s_3+j} \otimes ((SA)_2 S_2)_i \otimes ((SA)_3 S_3)_j - A \right\|_v \\
= & \min_{U \in \mathbb{R}^{n \times s_2 s_3}} \left\| \sum_{i=1}^{s_2} \sum_{j=1}^{s_3} U_{(i-1)s_3+j} \cdot \mathrm{vec}(((SA)_2 S_2)_i \otimes ((SA)_3 S_3)_j) - A_1 \right\|_v \\
= & \min_{U \in \mathbb{R}^{n \times s_2 s_3}} \left\| \sum_{i=1}^{s_2} \sum_{j=1}^{s_3} U_{(i-1)s_3+j} \cdot (\widetilde{V}^\top \odot \widetilde{W}^\top)^{(i-1)s_3+j} - A_1 \right\|_v \\
= & \min_{U \in \mathbb{R}^{n \times s_2 s_3}} \left\| U \cdot (\widetilde{V}^\top \odot \widetilde{W}^\top) - A_1 \right\|_v \\
= & \min_{U \in \mathbb{R}^{n \times s_2 s_3}} \| UZ - A_1 \|_v \\
= & \min_{U \in \mathbb{R}^{n \times s_2 s_3}} \sum_{i=1}^{s_2 s_3} \| U^i Z - A_1^i \|_2,
\end{aligned}$$

where the first step follows by flattening the tensor along the 1st dimension, $U_{(i-1)s_3+j}$ denotes the $(i-1)s_3 + j$-th column of $U \in \mathbb{R}^{n \times s_2 s_3}$, $A_1 \in \mathbb{R}^{n \times n^2}$ denotes the matrix obtained by flattening tensor A along the 1st dimension, the second step follows since $\widetilde{V}^\top \odot \widetilde{W}^\top \in \mathbb{R}^{s_2 s_3 \in n^2}$ is defined to be the matrix where the $(i-1)s_3 + j$-th row is vectorization of $((SA)_2 S_2)_i \otimes ((SA)_3 S_3)_j$, the fourth step follows by defining Z to be $\widetilde{V}^\top \odot \widetilde{W}^\top$, and the last step follows by definition of $\| \cdot \|_v$ norm. Thus, we obtain a multiple regression problem and it can be solved directly by using [CW13, NN13a].

Finally, we take the best $\widetilde{U}, \widetilde{V}, \widetilde{W}$ over all the guesses. The entire running time is dominated by the number of guesses, which is $n^{\mathrm{poly}(k)}$. This completes the proof. □

Theorem 21.12.17. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, for any $k \geq 1$, let $r = O(k^2)$. There exists an algorithm which takes $O(\mathrm{nnz}(A)) + n\,\mathrm{poly}(k, \log n)$ time and outputs three*

matrices $U, V, W \in \mathbb{R}^{n \times r}$ *such that*

$$\|U \otimes V \otimes W - A\|_v \leq \text{poly}(k, \log n) \min_{\text{rank}-k\ A'} \|A' - A\|_v$$

holds with probability at least $9/10$.

Proof. We define OPT as follows,

$$\text{OPT} = \min_{U,V,W \in \mathbb{R}^{n \times k}} \|U \otimes V \otimes W - A\|_v = \min_{U,V,W \in \mathbb{R}^{n \times k}} \left\| \sum_{i=1}^{k} U_i \otimes V_i \otimes W_i - A \right\|_v .$$

Let $A_1 \in \mathbb{R}^{n \times n^2}$ denote the matrix obtained by flattening tensor A along the 1st dimension. Let $U^* \in \mathbb{R}^{n \times k}$ denote the optimal solution. We fix $U^* \in \mathbb{R}^{n \times k}$, and consider the objective function,

$$\min_{V,W \in \mathbb{R}^{n \times k}} \|U^* \otimes V \otimes W - A\|_v \equiv \min_{V,W \in \mathbb{R}^{n \times k}} \left\|U^* \cdot (V^\top \odot W^\top) - A_1\right\|_v , \tag{21.66}$$

which has cost at most OPT, and where $V^\top \odot W^\top \in \mathbb{R}^{k \times n^2}$ denotes the matrix for which the i-th row is a vectorization of $V_i \otimes W_i, \forall i \in [k]$. (Note that $V_i \in \mathbb{R}^n$ is the i-th column of matrix $V \in \mathbb{R}^{n \times k}$). Choose an (oblivious) MSketch $S \in \mathbb{R}^{s \times n}$ with $s = \mathrm{poly}(k, \log n)$ according to Definition 21.12.5. Using MSketch S, w to sketch on the left of the objective function when U^* is fixed (Equation (21.66)), we obtain a smaller problem,

$$\min_{V,W \in \mathbb{R}^{n \times k}} \|(SU^*) \otimes V \otimes W - SA\|_v \equiv \min_{V,W \in \mathbb{R}^{n \times k}} \left\|SU^* \cdot (V^\top \odot W^\top) - SA_1\right\|_v . \tag{21.67}$$

Let V', W' denote the optimal solution to the above problem, i.e.,

$$V', W' = \arg\min_{V,W \in \mathbb{R}^{n \times k}} \|(SU^*) \otimes V \otimes W - SA\|_v .$$

Then using properties (no dilation Lemma 21.12.13 and no contraction Lemma 21.12.14) of S, we have

$$\|U^* \otimes V' \otimes W' - A\|_v \leq \alpha \, \mathrm{OPT} .$$

where α is an approximation ratio determined by S.

By definition of $\|\cdot\|_v$ and $\|\cdot\|_2 \leq \|\cdot\|_1 \leq \sqrt{\dim}\|\cdot\|_2$, we can rewrite Equation (21.67)

in the following way,

$$\begin{aligned}
&\|(SU^*) \otimes V \otimes W - SA\|_v \\
&= \sum_{i=1}^{s} \left(\sum_{j=1}^{n} \sum_{l=1}^{n} \left(((SU^*) \otimes V \otimes W)_{i,j,l} - (SA)_{i,j,l} \right)^2 \right)^{\frac{1}{2}} \\
&\leq \sqrt{s} \left(\sum_{i=1}^{s} \sum_{j=1}^{n} \sum_{l=1}^{n} \left(((SU^*) \otimes V \otimes W)_{i,j,l} - (SA)_{i,j,l} \right)^2 \right)^{\frac{1}{2}} \\
&= \sqrt{s} \, \|(SU^*) \otimes V \otimes W - SA\|_F
\end{aligned} \tag{21.68}$$

Using the properties of S and Equation (21.68), for any $\beta \geq 1$, let V'', W'' denote a β-approximation solution of $\min_{V,W \in \mathbb{R}^{n \times k}} \|(SU^*) \otimes V \otimes W - SA\|_F$, i.e.,

$$\|(SU^*) \otimes V'' \otimes W'' - SA\|_F \leq \beta \cdot \min_{V,W \in \mathbb{R}^{n \times k}} \|(SU^*) \otimes V \otimes W - SA\|_F . \tag{21.69}$$

Then,

$$\|U^* \otimes V'' \otimes W'' - A\|_v \leq \sqrt{s}\alpha\beta \cdot \mathrm{OPT} . \tag{21.70}$$

Let $\widehat{A}$ denote SA. Choose $S_i \in \mathbb{R}^{ns \times s_i}$ to be Gaussian matrix with $s_i = O(k/\epsilon)$, $\forall i \{2, 3\}$. By a similar proof as in Theorem 21.12.16, we have if X_2', X_3' is a β-approximate solution to

$$\min_{X_2, X_3} \|(SU^*) \otimes (\widehat{A}_2 S_2 X_2) \otimes (\widehat{A}_3 S_3 X_3) - SA\|_F,$$

then,

$$\|U^* \otimes (\widehat{A}_2 S_2 X_2) \otimes (\widehat{A}_3 S_3 X_3) - A\|_v \leq \sqrt{s}\alpha\beta.$$

To reduce the size of the objective function from poly(n) to poly(k/ϵ), we use perform an "input sparsity reduction" (in Lemma 21.4.3). Note that, we do not need to use this idea to optimize the running time in Theorem 21.12.16. The running time of Theorem 21.12.16 is dominated by guessing sampling and rescaling matrices. (That running time is $\gg \text{nnz}(A)$.) Choose $T_i \in \mathbb{R}^{t_i \times n}$ to be a sparse subspace embedding matrix (CountSketch transform) with $t_i = \text{poly}(k, 1/\epsilon)$, $\forall i \in \{2, 3\}$. Applying the proof of Lemma 21.4.3 here, we obtain, if X_2', X_3' is a β-approximate solution to

$$\min_{X_2, X_3} \|(SU^*) \otimes (T_2(SA)_2 S_2 X_2) \otimes (T_3(SA)_3 S_3 X_3) - SA\|_F,$$

then,

$$\|U^* \otimes ((SA)_2 S_2 X_2) \otimes ((SA)_3 S_3 X_3) - A\|_v \leq \sqrt{s}\alpha\beta. \tag{21.71}$$

Similar to the bicriteria results in Section 21.4.4, Equation (21.71) indicates that we can construct a bicriteria solution by using two matrices $(SA)_2 S_2$ and $(SA)_3 S_3$. The next question is how to obtain the final results $\widehat{U}, \widehat{V}, \widehat{W}$. We first show how to obtain $\widehat{U}$. Then we show to construct $\widehat{V}$ and $\widehat{W}$.

To obtain $\widehat{U}$, we need to solve a regression problem related to two matrices $\overline{V}, \widehat{W}$ and a tensor $A(I, T_2, T_3)$. We construct matrix $\overline{V} \in \mathbb{R}^{t_2 \times s_2 s_3}$ by copying matrix $T_2(SA)_2 S_2 \in \mathbb{R}^{t_2 \times s_2}$ s_3 times,

$$\overline{V} = \begin{bmatrix} T_2(SA)_2 S_2 & T_2(SA)_2 S_2 & \cdots & T_2(SA)_2 S_2 \end{bmatrix}. \tag{21.72}$$

We construct matrix $\overline{W} \in \mathbb{R}^{t_3 \times s_2 s_3}$ by copying the i-th column of matrix $T_3(SA)_3 S_3 \in \mathbb{R}^{t_3 \times s_3}$ into $(i-1)s_2 + 1, \cdots, is_2$ columns of $\overline{W}$,

$$\overline{W} = \begin{bmatrix} F_1 \cdots F_1 & F_2 \cdots F_2 & \cdots & F_{s_3} \cdots F_{s_3} \end{bmatrix}, \tag{21.73}$$

where $F = T_3(SA)_3 S_3$.

Thus, to obtain $\widetilde{U} \in \mathbb{R}^{s_2 s_3}$, we just need to use a linear regression solver to solve a smaller problem,

$$\min_{U \in \mathbb{R}^{s_2 s_3}} \|U \cdot (\overline{V}^\top \odot \overline{W}^\top) - A(I, T_2, T_3)\|_F,$$

which can be solved in $O(\mathrm{nnz}(A)) + n\,\mathrm{poly}(k, \log n)$ time. We will show how to obtain $\widetilde{V}$ and $\widetilde{W}$.

We construct matrix $\widetilde{V} \in \mathbb{R}^{n \times s_2 s_3}$ by copying matrix $(SA)_2 S_2 \in \mathbb{R}^{n \times s_2}$ s_3 times,

$$\widetilde{V} = \begin{bmatrix} (SA)_2 S_2 & (SA)_2 S_2 & \cdots & (SA)_2 S_2 . \end{bmatrix} \tag{21.74}$$

We construct matrix $\widetilde{W} \in \mathbb{R}^{n \times s_2 s_3}$ by copying the i-th column of matrix $(SA)_3 S_3 \in \mathbb{R}^{n \times s_3}$ into $(i-1)s_2 + 1, \cdots, i s_2$ columns of $\widetilde{W}$,

$$\widetilde{W} = \begin{bmatrix} F_1 \cdots F_1 & F_2 \cdots F_2 & \cdots & F_{s_3} \cdots F_{s_3} \end{bmatrix}, \tag{21.75}$$

where $F = (SA)_3 S_3$. □

21.12.3 ℓ_1-ℓ_1-ℓ_2 norm

Section 21.12.3.1 presents some definitions and useful facts for the tensor ℓ_1-ℓ_1-ℓ_2 norm. We provide some tools in Section 21.12.3.2. Section 21.12.3.3 presents a key idea which shows we are able to reduce the original problem to a new problem under entry-wise ℓ_1 norm. Section 21.12.3.4 presents several existence results. Finally, Section 21.12.3.6 introduces several algorithms with different tradeoffs.

21.12.3.1 Definitions

Definition 21.12.7. (Tensor u-norm) For an $n \times n \times n$ tensor A, we define the u-norm of A, denoted $\|A\|_u$, to be

$$\left(\sum_{i=1}^{n}\sum_{j=1}^{n} M(\|A_{i,j,*}\|_2)\right)^{1/p},$$

where $A_{i,j,*}$ is the (i,j)-th tube of A, and p is a parameter associated with the function $M()$, which defines a nice M-Estimator.

Definition 21.12.8. (Matrix u-norm) For an $n \times n$ matrix A, we define u-norm of A, denoted $\|A\|_u$, to be

$$\left(\sum_{i=1}^{n} M(\|A_{i,*}\|_2)\right)^{1/p},$$

where $A_{i,*}$ is the i-th row of A, and p is a parameter associated with the function $M()$, which defines a nice M-Estimator.

Fact 21.12.18. *For $p = 1$, for any two matrices A and B, we have $\|A+B\|_u \leq \|A\|_u + \|B\|_u$. For any two tensors A and B, we have $\|A + B\|_u \leq \|A\|_u + \|B\|_u$.*

21.12.3.2 Projection via Gaussians

Definition 21.12.9. Let $p \geq 1$. Let $\ell_p^{\mathcal{S}^{n-1}}$ be an infinite dimensional ℓ_p metric which consists of a coordinate for each vector r in the unit sphere $\mathcal{S}^{n-1}$. Define function $f : \mathcal{S}^{n-1} \to \mathbb{R}$. The ℓ_1-norm of any such f is defined as follows:

$$\|f\|_1 = \left(\int_{r \in \mathcal{S}^{n-1}} |f(r)|^p \mathrm{d}r \right)^{1/p}.$$

Claim 21.12.19. *Let $f_v(r) = \langle v, r \rangle$. There exists a universal constant α_p such that*

$$\|f_v\|_p = \alpha_p \|v\|_2.$$

Proof. We have,

$$\begin{aligned} \|f_v\|_p = & \left(\int_{r \in \mathcal{S}^{n-1}} |\langle v, r \rangle|^p \mathrm{d}r \right)^{1/p} \\ = & \left(\int_{\theta \in \mathcal{S}^{n-1}} \|v\|_2^p \cdot |\cos\theta|^p \mathrm{d}\theta \right)^{1/p} \\ = & \|v\|_2 \left(\int_{\theta \in \mathcal{S}^{n-1}} |\cos\theta|^p \mathrm{d}\theta \right)^{1/p} \\ = & \alpha_p \|v\|_2. \end{aligned}$$

This completes the proof. □

Lemma 21.12.20. *Let $G \in \mathbb{R}^{k \times n}$ denote i.i.d. random Gaussian matrices with rescaling. Then for any $v \in \mathbb{R}^n$, we have*

$$\Pr[(1-\epsilon)\|v\|_2 \leq \|Gv\|_1 \leq (1+\epsilon)\|v\|_2] \geq 1 - 2^{-\Omega(k\epsilon^2)}.$$

Proof. For each $i \in [k]$, we define $X_i = \langle v, g_i \rangle$, where $g_i \in \mathbb{R}^n$ is the i-th row of G. Then $X_i = \sum_{j=1}^n v_j g_{i,j}$ and $\mathbb{E}[|X_i|] = \alpha_p \|v\|_2$. Define $Y = \sum_{i=1}^k |X_i|$. We have $\mathbb{E}[Y] = k\alpha_1 \|v\|_2 = k\alpha_1$.

We can show

$$\begin{aligned}
\Pr[Y \geq (1+\epsilon)\alpha_1 k] =& \Pr[e^{sY} \geq e^{s(1+\epsilon)\alpha_1 k}] && \text{for all } s > 0 \\
\leq& \mathbb{E}[e^{sY}]/e^{s(1+\epsilon)\alpha_1 k} && \text{by Markov's inequality} \\
=& e^{-s(1+\epsilon)\alpha_1 k} \cdot \mathbb{E}[\prod_{i=1}^{k} e^{s|X_i|}] && \text{by } Y = \sum_{i=1}^{k} |X_i| \\
=& e^{-s(1+\epsilon)\alpha_1 k} \cdot (\mathbb{E}[e^{s|X_1|}])^k
\end{aligned}$$

It remains to bound $\mathbb{E}[e^{s|X_1|}]$. Since $X_1 \sim \mathcal{N}(0,1)$, we have that X_1 has density function $e^{-t^2/2}$. Thus, we have,

$$\begin{aligned}
\mathbb{E}[e^{s|X_1|}] &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} e^{s|t|} \cdot e^{-t^2/2} \mathrm{d}t \\
&= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} e^{s^2/2} \cdot e^{-(|t|-s)^2/2} \mathrm{d}t \\
&= e^{s^2/2}(\mathrm{erf}(s/\sqrt{2}) + 1) \\
&\leq e^{s^2/2}((1-\exp(-2s^2/\pi))^{1/2} + 1) && \text{by } 1-\exp(-4x^2/\pi) \geq \mathrm{erf}(x)^2 \\
&\leq e^{s^2/2}(\sqrt{2/\pi}s + 1). && \text{by } 1 - e^{-x} \leq x
\end{aligned}$$

Thus, we have

$$\begin{aligned}
\Pr[Y \geq (1+\epsilon)\alpha_1 k] &\leq e^{-s(1+\epsilon)k} e^{ks^2/2} (1 + s\sqrt{2/\pi})^k \\
&= e^{-s(1+\epsilon)\alpha_1 k} e^{ks^2/2} e^{k \cdot \log(1+s\sqrt{2/\pi})} \\
&\leq e^{-s(1+\epsilon)\alpha_1 k + ks^2/2 + k \cdot s\sqrt{2/\pi}} \\
&\leq e^{-\Omega(k\epsilon^2)}. && \text{by } \alpha_1 \geq \sqrt{2/\pi} \text{ and setting } s = \epsilon
\end{aligned}$$

□

Lemma 21.12.21. *For any $\epsilon \in (0,1)$, let $k = O(n/\epsilon^2)$. Let $G \in \mathbb{R}^{k \times n}$ denote i.i.d. random Gaussian matrices with rescaling. Then for any $v \in \mathbb{R}^n$, with probability at least $1 - 2^{-\Omega(n/\epsilon^2)}$, we have : for all $v \in \mathbb{R}^n$,*

$$(1-\epsilon)\|v\|_2 \leq \|Gv\|_1 \leq (1+\epsilon)\|v\|_2.$$

Proof. Let $\mathcal{S}$ denote $\{y \in \mathbb{R}^n \mid \|y\|_2 = 1\}$. We construct a γ-net so that for all $y \in \mathcal{S}$, there exists a vector $w \in \mathcal{N}$ for which $\|y - w\|_2 \leq \gamma$. We set $\gamma = 1/2$.

For any unit vector y, we can write

$$y = y^0 + y^1 + y^2 + \cdots,$$

where $\|y^i\|_2 \leq 1/2^i$ and y^i is a scalar multiple of a vector in $\mathcal{N}$. Thus, we have

$$\begin{aligned}
\|Gy\|_1 &= \|G(y^0 + y^1 + y^2 + \cdots)\|_1 \\
&\leq \sum_{i=0}^{\infty} \|Gy^i\|_1 && \text{by triangle inequality} \\
&\leq \sum_{i=0}^{\infty} (1+\epsilon)\|y^i\|_2 \\
&\leq \sum_{i=0}^{\infty} (1+\epsilon)\frac{1}{2^i} \\
&\leq 1 + \Theta(\epsilon).
\end{aligned}$$

Similarly, we can lower bound $\|Gy\|_1$ by $1 - \Theta(\epsilon)$. By Lemma 2.2 in [Woo14b], we know that for any $\gamma \in (0,1)$, there exists a γ-net $\mathcal{N}$ of $\mathcal{S}$ for which $|\mathcal{N}| \leq (1 + 4/\gamma)^n$. □

21.12.3.3 Reduction, projection to high dimension

Lemma 21.12.22. *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$, let $S \in \mathbb{R}^{n \times s}$ denote a Gaussian matrix with $s = O(n/\epsilon^2)$ columns. With probability at least $1 - 2^{-\Omega(n/\epsilon^2)}$, for any $U, V, W \in$*

$\mathbb{R}^{n\times k}$, *we have*

$$(1-\epsilon)\left\|U\otimes V\otimes W-A\right\|_u \le \left\|(U\otimes V\otimes W)S-AS\right\|_1 \le (1+\epsilon)\left\|U\otimes V\otimes W-A\right\|_u.$$

Proof. By definition of the $\otimes$ product between matrices and $\cdot$ product between a tensor and a matrix, we have $(U\otimes V\otimes W)S = U\otimes V\otimes(SW)\in\mathbb{R}^{n\times n\times s}$. We use $A_{i,j,*}\in\mathbb{R}^n$ to denote the (i,j)-th tube (the column in the 3rd dimension) of tensor A. We first prove the upper bound,

$$\begin{aligned}\left\|(U\otimes V\otimes W)S-AS\right\|_1 &= \sum_{i=1}^n\sum_{j=1}^n \left\|\left((U\otimes V\otimes W)_{i,j,*}-A_{i,j,*}\right)S\right\|_1\\ &\le \sum_{i=1}^n\sum_{j=1}^n (1+\epsilon)\left\|(U\otimes V\otimes W)_{i,j,*}-A_{i,j,*}\right\|_2\\ &= (1+\epsilon)\left\|U\otimes V\otimes W-A\right\|_u,\end{aligned}$$

where the first step follows by definition of tensor $\|\cdot\|_u$ norm, the second step follows by Lemma 21.12.21, and the last step follows by tensor entry-wise ℓ_1 norm. Similarly, we can prove the lower bound,

$$\begin{aligned}\left\|(U\otimes V\otimes W)S-AS\right\|_1 &\ge \sum_{i=1}^n\sum_{j=1}^n (1-\epsilon)\left\|(U\otimes V\otimes W)_{i,j,*}-A_{i,j,*}\right\|_2\\ &= (1-\epsilon)\left\|U\otimes V\otimes W-A\right\|_u.\end{aligned}$$

This completes the proof. □

Corollary 21.12.23. *For any $\alpha\ge 1$, if U',V',W' satisfy*

$$\left\|(U'\otimes V'\otimes W'-A)S\right\|_1 \le \gamma \min_{\mathrm{rank}-k\ A_k}\left\|(A_k-A)S\right\|_1,$$

then

$$\left\|U'\otimes V'\otimes W'-A\right\|_u \le \gamma\frac{1+\epsilon}{1-\epsilon}\min_{\mathrm{rank}-k\ A_k}\left\|A_k-A\right\|_u.$$

Proof. Let $\widehat{U}, \widehat{V}, \widehat{W}$ denote the optimal solution to $\min_{\text{rank}-k\ A_k} \|(A_k - A)S\|_1$. Let U^*, V^*, W^* denote the optimal solution to $\min_{\text{rank}-k\ A_k} \|A_k - A\|_u$. Then,

$$\begin{aligned}
\|U' \otimes V' \otimes W' - A\|_u &\leq \frac{1}{1-\epsilon} \|(U' \otimes V' \otimes W' - A)S\|_1 \\
&\leq \gamma \frac{1}{1-\epsilon} \|(\widehat{U} \otimes \widehat{V} \otimes \widehat{W} - A)S\|_1 \\
&\leq \gamma \frac{1}{1-\epsilon} \|(U^* \otimes V^* \otimes W^* - A)S\|_1 \\
&\leq \gamma \frac{1+\epsilon}{1-\epsilon} \|U^* \otimes V^* \otimes W^* - A\|_u,
\end{aligned}$$

which completes the proof. □

21.12.3.4 Existence results

Theorem 21.12.24 (Existence results)**.** *Given a 3rd order tensor $A \in \mathbb{R}^{n \times n \times n}$ and a matrix $S \in \mathbb{R}^{n \times \overline{n}}$, let* OPT *denote* $\min_{\text{rank}-k\ A_k \in \mathbb{R}^{n \times n \times n}} \|(A_k - A)S\|_1$*, let $\widehat{A} = AS \in \mathbb{R}^{n \times n \times \overline{n}}$. For any $k \geq 1$, there exist three matrices $S_1 \in \mathbb{R}^{n\overline{n} \times s_1}$, $S_2 \in \mathbb{R}^{n\overline{n} \times s_2}$, $S_3 \in \mathbb{R}^{n^2 \times s_3}$ such that*

$$\min_{X_1 \in \mathbb{R}^{s_1 \times k}, X_2 \in \mathbb{R}^{s_2 \times k}, X_3 \in \mathbb{R}^{s_3 \times k}} \left\| (\widehat{A}_1 S_1 X_1) \otimes (\widehat{A}_2 S_2 X_2) \otimes (\widehat{A}_3 S_3 X_3) - \widehat{A} \right\|_1 \leq \alpha\, \text{OPT},$$

or equivalently,

$$\min_{X_1 \in \mathbb{R}^{s_1 \times k}, X_2 \in \mathbb{R}^{s_2 \times k}, X_3 \in \mathbb{R}^{s_3 \times k}} \left\| \left((\widehat{A}_1 S_1 X_1) \otimes (\widehat{A}_2 S_2 X_2) \otimes (A_3 S_3 X_3) - A \right) S \right\|_1 \leq \alpha\, \text{OPT},$$

holds with probability 99/100*.*

(I). *Using a dense Cauchy transform,*
$s_1 = s_2 = s_3 = \widetilde{O}(k)$, $\alpha = \widetilde{O}(k^{1.5}) \log^3 n$.

(II). *Using a sparse Cauchy transform,*
$s_1 = s_2 = s_3 = \widetilde{O}(k^5)$, $\alpha = \widetilde{O}(k^{13.5}) \log^3 n$.

(III). *Guessing Lewis weights,*

$s_1 = s_2 = s_3 = \widetilde{O}(k)$, $\alpha = \widetilde{O}(k^{1.5})$.

Proof. We use OPT to denote the optimal cost,

$$\mathrm{OPT} := \min_{\mathrm{rank}-k\ A_k \in \mathbb{R}^{n\times n\times n}} \|(A_k - A)S\|_1.$$

We fix $V^* \in \mathbb{R}^{n\times k}$ and $W^* \in \mathbb{R}^{n\times k}$ to be the optimal solution to

$$\min_{U,V,W} \|(U \otimes V \otimes W - A)S\|_1.$$

We define $Z_1 \in \mathbb{R}^{k\times n\overline{n}}$ to be the matrix where the i-th row is the vectorization of $V_i^* \otimes (SW_i^*)$. We define tensor

$$\widehat{A} = AS \in \mathbb{R}^{n\times n\times \overline{n}}.$$

Then we also have $\widehat{A} = A(I, I, S)$ according to the definition of the $\cdot$ product between a tensor and a matrix.

Let $\widehat{A}_1 \in \mathbb{R}^{n\times n\overline{n}}$ denote the matrix obtained by flattening tensor $\widehat{A}$ along the first direction. We can consider the following optimization problem,

$$\min_{U\in\mathbb{R}^{n\times k}} \left\| UZ_1 - \widehat{A}_1 \right\|_1.$$

Choosing S_1 to be one of the following sketching matrices:

(I) a dense Cauchy transform,

(II) a sparse Cauchy transform,

(III) a sampling and rescaling diagonal matrix according to Lewis weights.

Let α_{S_1} denote the approximation ratio produced by the sketching matrix S_1. We use $S_1 \in \mathbb{R}^{n\overline{n}\times s_1}$ to sketch on right of the above problem, and obtain the problem:

$$\min_{U\in\mathbb{R}^{n\times k}} \|UZ_1S_1 - \widehat{A}_1S_1\|_1 = \min_{U\in\mathbb{R}^{n\times k}} \sum_{i=1}^{n} \|U^iZ_1S_1 - (\widehat{A}_1S_1)^i\|_1,$$

where U^i denotes the i-th row of matrix $U \in \mathbb{R}^{n\times k}$ and $(\widehat{A}_1S_1)^i$ denotes the i-th row of matrix $\widehat{A}_1S_1$. Instead of solving it under ℓ_1-norm, we consider the ℓ_2-norm relaxation,

$$\min_{U\in\mathbb{R}^{n\times k}} \|UZ_1S_1 - \widehat{A}_1S_1\|_F^2 = \min_{U\in\mathbb{R}^{n\times k}} \sum_{i=1}^{n} \|U^iZ_1S_1 - (\widehat{A}_1S_1)^i\|_2^2.$$

Let $\widehat{U} \in \mathbb{R}^{n\times k}$ denote the optimal solution of the above optimization problem, so that $\widehat{U} = \widehat{A}_1S_1(Z_1S_1)^\dagger$. We plug $\widehat{U}$ into the objective function under the ℓ_1-norm. By the property of sketching matrix $S_1 \in \mathbb{R}^{n\overline{n}\times s_1}$, we have,

$$\|\widehat{U}Z_1 - \widehat{A}_1\|_1 \leq \alpha_{S_1} \min_{U\in\mathbb{R}^{n\times k}} \|UZ_1 - \widehat{A}_1\|_1 = \alpha_{S_1}\,\mathrm{OPT},$$

which implies that,

$$\|\widehat{U}\otimes V^*\otimes(SW^*) - \widehat{A}\|_1 = \|(\widehat{U}\otimes V^*\otimes W^*)S - \widehat{A}\|_1 \leq \alpha_{S_1}\,\mathrm{OPT}\,.$$

In the second step, we fix $\widehat{U} \in \mathbb{R}^{n\times k}$ and $W^* \in \mathbb{R}^{n\times k}$. Let $\widehat{A}_2 \in \mathbb{R}^{n\times n\overline{n}}$ denote the matrix obtained by flattening tensor $\widehat{A} \in \mathbb{R}^{n\times n\times\overline{n}}$ along the second direction. We choose a sketching matrix $S_2 \in \mathbb{R}^{n\overline{n}\times s_2}$. Let $Z_2 = \widehat{U}^\top \odot (SW^*)^\top \in \mathbb{R}^{k\times n\overline{n}}$ denote the matrix where the i-th row is the vectorization of $\widehat{U}_i \otimes (SW_i^*)$. Define $\widehat{V} = \widehat{A}_2S_2(Z_2S_2)^\dagger$. By the properties of sketching matrix S_2, we have

$$\|\widehat{V}Z_2 - \widehat{A}_2\|_1 \leq \alpha_{S_2}\alpha_{S_1}\,\mathrm{OPT},$$

In the third step, we fix $\widehat{U} \in \mathbb{R}^{n\times k}$ and $\widehat{V} \in \mathbb{R}^{n\times k}$. Let $\widehat{A}_3 \in \mathbb{R}^{\overline{n}\times n^2}$ denote the matrix obtained by flattening tensor $\widehat{A} \in \mathbb{R}^{n\times n\times \overline{n}}$ along the third direction. We choose a sketching matrix $S_3 \in \mathbb{R}^{n^2\times s_3}$. Let $Z_3 \in \mathbb{R}^{k\times n^2}$ denote the matrix where the i-th row is the vectorization of $\widehat{U}_i \otimes \widehat{V}_i$. Define $W' = \widehat{A}_3 S_3 (Z_3 S_3)^\dagger \in \mathbb{R}^{\overline{n}\times k}$ and $\widehat{W} = A_3 S_3 (Z_3 S_3)^\dagger \in \mathbb{R}^{n\times k}$. Then we have,

$$\begin{aligned} W' &= \widehat{A}_3 S_3 (Z_3 S_3)^\dagger \\ &= (A(I,I,S))_3 S_3 (Z_3 S_3)^\dagger \\ &= (S^\top A_3) S_3 (Z_3 S_3)^\dagger \\ &= S^\top \widehat{W} \end{aligned}$$

By properties of sketching matrix S_3, we have

$$\|W' Z_3 - \widehat{A}_3\|_1 \leq \alpha_{S_3}\alpha_{S_2}\alpha_{S_1}\,\mathrm{OPT}\,.$$

Replacing W' by $S^\top \widehat{W}$, we obtain,

$$\|W' Z_3 - \widehat{A}_3\|_1 = \|S^\top \widehat{W} Z_3 - \widehat{A}_3\|_1 = \|S^\top \widehat{W} Z_3 - S^\top A_3\|_1 = \|(\widehat{U}\otimes\widehat{V}\otimes\widehat{W} - A)S\|_1.$$

Thus, we have

$$\min_{X_1\in\mathbb{R}^{s_1\times k}, X_2\in\mathbb{R}^{s_2\times k}, X_3\in\mathbb{R}^{s_3\times k}} \left\|(\widehat{A}_1 S_1 X_1)\otimes(\widehat{A}_2 S_2 X_2)\otimes(\widehat{A}_3 S_3 X_3) - \widehat{A}\right\|_1 \leq \alpha_{S_1}\alpha_{S_2}\alpha_{S_3}\,\mathrm{OPT}\,.$$

□

21.12.3.5 Running time analysis

Fact 21.12.25. *Given tensor $A \in \mathbb{R}^{n\times n\times n}$ and a matrix $B \in \mathbb{R}^{n\times d}$ with $d = O(n)$, let AB denote an $n \times n \times d$ size tensor, For each $i \in [3]$, let $(AB)_i$ denote a matrix obtained by*

flattening tensor AB along the i-th dimension, then

$$(AB)_1 \in \mathbb{R}^{n \times nd}, (AB)_2 \in \mathbb{R}^{n \times nd}, (AB)_3 \in \mathbb{R}^{d \times n^2}.$$

For each $i \in [3]$, let $S_i \in \mathbb{R}^{nd \times s_i}$ denote a sparse Cauchy transform, $T_i \in \mathbb{R}^{t_i \times n}$. Then we have,

(I) *If T_1 denotes a sparse Cauchy transform or a sampling and rescaling matrix according to the Lewis weights, $T_1(AB)_1 S_1$ can be computed in $O(\mathrm{nnz}(A)d)$ time. Otherwise, it can be computed in $O(\mathrm{nnz}(A)d + ns_1t_1)$.*

(II) *If T_2 denotes a sparse Cauchy transform or a sampling and rescaling matrix according to the Lewis weights, $T_2(AB)_2 S_2$ can be computed in $O(\mathrm{nnz}(A)d)$ time. Otherwise, it can be computed in $O(\mathrm{nnz}(A)d + ns_2t_2)$.*

(III) *If T_3 denotes a sparse Cauchy transform or a sampling and rescaling matrix according to the Lewis weights, $T_3(AB)_3 S_3$ can be computed in $O(\mathrm{nnz}(A)d)$ time. Otherwise, it can be computed in $O(\mathrm{nnz}(A)d + ds_3t_3)$.*

Proof. Part (I). Note that $T_1(AB)_1S_1 \in \mathbb{R}^{t_1\times s_1}$ and $(AB)_1 \in \mathbb{R}^{n\times nd}$, for each $i \in [t_1], j \in [s_1]$,

$$\begin{aligned}
(T_1(AB)_1S_1)_{i,j} = & \sum_{x=1}^{n}\sum_{y'=1}^{nd}(T_1)_{i,x}((AB)_1)_{x,y'}(S_1)_{y',j} \\
= & \sum_{x=1}^{n}\sum_{y=1}^{n}\sum_{z=1}^{d}(T_1)_{i,x}((AB)_1)_{x,(y-1)d+z}(S_1)_{(y-1)d+z,j} \\
= & \sum_{x=1}^{n}\sum_{y=1}^{n}\sum_{z=1}^{d}(T_1)_{i,x}(AB)_{x,y,z}(S_1)_{(y-1)d+z,j} \\
= & \sum_{x=1}^{n}\sum_{y=1}^{n}\sum_{z=1}^{d}(T_1)_{i,x}\sum_{w=1}^{n}(A_{x,y,w}B_{w,z})(S_1)_{(y-1)d+z,j} \\
= & \sum_{x=1}^{n}\sum_{y=1}^{n}(T_1)_{i,x}\sum_{w=1}^{n}A_{x,y,w}\sum_{z=1}^{d}B_{w,z}(S_1)_{(y-1)d+z,j}.
\end{aligned}$$

We look at a non-zero entry $A_{x,y,w}$ and the entry $B_{w,z}$. If T_1 denotes a sparse Cauchy transform or a sampling and rescaling matrix according to the Lewis weights, then there is at most one pair (i,j) such that $(T_1)_{i,x}A_{x,y,w}B_{w,z}(S_1)_{(y-1)d+z,j}$ is non-zero. Therefore, computing $T_1(AB)_1S_1$ only needs $\mathrm{nnz}(A)d$ time. If T_1 is not in the above case, since S_1 is sparse, we can compute $(AB)_1S_1$ in $\mathrm{nnz}(A)d$ time by a similar argument. Then, we can compute $T_1(AB)_1S_1$ in nt_1s_1 time.

Part (II). It is as the same as Part (I).

Part (III). Note that $T_3(AB)_3S_3 \in \mathbb{R}^{t_3\times s_3}$ and $(AB)_3 \in \mathbb{R}^{d\times n^2}$. For each $i \in [t_3], j \in$

$[s_3]$,

$$\begin{aligned}
(T_3(AB)_3S_3)_{i,j} = & \sum_{x=1}^{d}\sum_{y'=1}^{n^2}(T_3)_{i,x}((AB)_3)_{x,y'}(S_3)_{y',j} \\
= & \sum_{x=1}^{d}\sum_{y=1}^{n}\sum_{z=1}^{n}(T_3)_{i,x}((AB)_3)_{x,(y-1)n+z}(S_3)_{(y-1)n+z,j} \\
= & \sum_{x=1}^{d}\sum_{y=1}^{n}\sum_{z=1}^{n}(T_3)_{i,x}(AB)_{y,z,x}(S_3)_{(y-1)n+z,j} \\
= & \sum_{x=1}^{d}\sum_{y=1}^{n}\sum_{z=1}^{n}(T_3)_{i,x}\sum_{w=1}^{n}A_{y,z,w}B_{w,x}(S_3)_{(y-1)n+z,j}
\end{aligned}$$

Similar to Part (I), if T_1 denotes a sparse Cauchy transform or a sampling and rescaling matrix according to the Lewis weights, computing $T_3(AB)_3S_3$ only needs $\mathrm{nnz}(A)d$ time. Otherwise, it needs $dt_3s_3 + \mathrm{nnz}(A)d$ running time.

□

21.12.3.6 Algorithms

Theorem 21.12.26. *Given a 3rd order tensor $A \in \mathbb{R}^{n\times n\times n}$, for any $k \geq 1$, there exists an algorithm which takes $O(\mathrm{nnz}(A)n) + \widetilde{O}(n)\,\mathrm{poly}(k) + n2^{\widetilde{O}(k^2)}$ time and outputs three matrices $U, V, W \in \mathbb{R}^{n\times k}$ such that,*

$$\|U \otimes V \otimes W - A\|_u \leq \mathrm{poly}(k, \log n) \min_{\mathrm{rank}-k\ A'} \|A' - A\|_u,$$

holds with probability at least $9/10$.

Proof. We first choose a Gaussian matrix $S \in \mathbb{R}^{n\times\overline{n}}$ with $\overline{n} = O(n)$. By applying Corollary 21.12.23, we can reduce the original problem to a "generalized" ℓ_1 low rank approximation

  Choose a sampling and rescaling diagonal matrix D_i according to the Lewis weights of $\widehat{A}_i S_i$ with t_i nonzero entries, for each $i \in \{2, 3\}$.
  Form $\widehat{V} \in \mathbb{R}^{n \times r}$ by setting the (i, j)-th column to be $(\widehat{A}_2 S_2)_i$.
  Form $\widehat{W} \in \mathbb{R}^{n \times r}$ by setting the (i, j)-th column to be $(A_3 S_3)_j$.
  Form matrix $B \in \mathbb{R}^{r \times t_2 t_3}$ by setting the (i, j)-th column to be the vectorization of $(T_2 \widehat{A}_2 S_2)_i \otimes (T_3 \widehat{A}_3 S_3)_j$.
  Solve $\min_U \| U \cdot B - (\widehat{A}(I, T_2, T_3))_1 \|_1$.
  return $\widehat{U}, \widehat{V}, \widehat{W}$
end procedure

Proof. We first choose a Gaussian matrix $S \in \mathbb{R}^{n \times \overline{n}}$ with $\overline{n} = O(n)$. By applying Corollary 21.12.23, we can reduce the original problem to a "generalized" ℓ_1 low rank approximation problem. Next, we use the existence results (Theorem 21.12.24) and polynomial in k size reduction (Lemma 21.7.5). At the end, we solve an entry-wise ℓ_1 norm objective function directly. □

21.13 Streaming Setting

One of the computation models which is closely related to the distributed model of computation is the streaming model. There is a growing line of work in the streaming model. Some problems are very fundamental in the streaming model such like Heavy Hitters [LNNT16, BCI+16, BCIW16], and streaming numerical linear algebra problems [CW09]. Streaming low rank matrix approximation has been extensively studied by previous work like [CW09, KL11, GP14, Lib13, KLM+14a, BWZ16, SWZ17]. In this section, we show that there is a streaming algorithm which can compute a low rank tensor approximation.

In the following, we introduce the turnstile streaming model and the turnstile streaming tensor Frobenius norm low rank approximation problem. The following gives a formal definition of the computation model we study.

Definition 21.13.1 (Turnstile model)**.** Initially, tensor $A \in \mathbb{R}^{n\times n\times n}$ is an all zero tensor. In the turnstile streaming model, there is a stream of update operations, and the i^{th} update operation is in the form $(x_i, y_i, z_i, \delta_i)$ where $x_i, y_i, z_i \in [n]$, and $\delta_i \in \mathbb{R}$ has $O(\log n)$ bits. Each $(x_i, y_i, z_i, \delta_i)$ means that A_{x_i,y_i,z_i} should be incremented by δ_i. And each entry of A has at most $O(\log n)$ bits at the end of the stream. An algorithm in this computation model is only allowed one pass over the stream. At the end of the stream, the algorithm stores a summary of A. The space complexity of the algorithm is the total number of words required to compute and store this summary while scanning the stream. Here, each word has at most $O(\log(n))$ bits.

The following is the formal definition of the problem.

Definition 21.13.2 (Turnstile model Frobenius norm rank-k tensor approximation)**.** Given tensor $A \in \mathbb{R}^{n\times n\times n}$, $k \in \mathbb{N}_+$ and an error parameter $1 > \epsilon > 0$, the goal is to design an algorithm in the streaming model of Definition 21.13.1 such that

1. Upon termination, the algorithm outputs three matrices $U^*, V^*, W^* \in \mathbb{R}^{n\times k}$.
2. U^*, V^*, W^* satisft that
$$\left\|\sum_{i=1}^{k} U_i^* \otimes V_i^* \otimes W_i^* - A\right\|_F^2 \leq (1+\epsilon) \min_{\text{rank}-k\ A'} \|A' - A\|_F^2.$$
3. The space complexity of the algorithm is as small as possible.

Theorem 21.13.1. *Suppose tensor $A \in \mathbb{R}^{n\times n\times n}$ is given in the turnstile streaming model (see Definition 21.13.1), there is an streaming algorithm (in Algorithm 21.41) which solves the problem in Definition 21.13.2 with constant success probability. In addition, the space complexity of the algorithm is* $\mathrm{poly}(k/\epsilon) + O(nk/\epsilon)$ *words.*

Proof. **Correctness.** Similar to the distributed protocol, the correctness of this streaming algorithm is also implied by Algorithm 21.2 and Algorithm 21.3 (Theorem 21.4.1.) Notice that at the end of the stream $V_1 = A_1S_1 \in \mathbb{R}^{n\times s_1}, V_2 = A_2S_2 \in \mathbb{R}^{n\times s_2}, V_3 = A_3S_3 \in \mathbb{R}^{n\times s_3}, C = A(T_1, T_2, T_3) \in \mathbb{R}^{t_1\times t_2\times t_3}$. It also means that

$$Y_1 = T_1A_1S_1, Y_2 = T_2A_2S_2, Y_3 = T_3A_3S_3.$$

According to line 26 of procedure TurnstileStreaming,

$$X_1^*, X_2^*, X_3^* = \arg\min_{X_1\in\mathbb{R}^{s_1\times k}, X_2\in\mathbb{R}^{s_2\times k}, X_3\in\mathbb{R}^{s_3\times k}} \left\|\sum_{j=1}^{k} (Y_1X_1)_j \otimes (Y_2X_2)_j \otimes (Y_3X_3)_j - C\right\|_F$$

According to Lemma 21.4.3, we have

$$\begin{aligned}
&\left\|\sum_{j=1}^{k}(Y_1X_1)_j\otimes(Y_2X_2)_j\otimes(Y_3X_3)_j-C\right\|_F^2\\
=&\left\|\sum_{j=1}^{k}(T_1A_1S_1X_1^*)_j\otimes(T_2A_2S_2X_2^*)_j\otimes(T_3A_3S_3X_3^*)_j-A(T_1,T_2,T_3)\right\|_F^2\\
\leq&(1+O(\epsilon))\min_{X_1,X_2,X_3}\left\|\sum_{j=1}^{k}(A_1S_1X_1)_j\otimes(A_2S_2X_2)_j\otimes(A_3Y_3X_3)_j-A\right\|_F^2\\
\leq&(1+O(\epsilon))\min_{U,V,W}\left\|\sum_{i=1}^{k}U_i\otimes V_i\otimes W_i-A\right\|_F^2,
\end{aligned}$$

where the last inequality follows by the proof of Theorem 21.4.1. By scaling a constant of ϵ, we complete the proof of correctness.

Space complexity. Since S_1, S_2, S_3 are w_1-wise independent, and T_1, T_2, T_3 are w_2-wise independent, the space needed to construct these sketching matrices in line 3 and line 5 of procedure TurnstileStreaming is $O(w_1 + w_2)$ words, where $w_1 = O(k), w_2 = O(1)$ (see [KVW14, CW13, Woo14b, KN14]). The cost to maintain V_1, V_2, V_3 is $O(nk/\epsilon)$ words, and the cost to maintain C is $\text{poly}(k/\epsilon)$ words.

Notice that, since each entry of A has at most $O(\log(sn))$ bits, each entry of Y_1, Y_2, Y_3, C has at most $O(\log(sn))$ bits. Due to Theorem 21.15.2, each entry of X_1^*, X_2^*, X_3^* has at most $O(\log(sn))$ bits, and the sizes of X_1^*, X_2^*, X_3^* are $\text{poly}(k/\epsilon)$ words. Thus the space cost in line 26 is $\text{poly}(k/\epsilon)$ words.

The total space cost is $\text{poly}(k/\epsilon) + O(nk/\epsilon)$ words. □

Remark 21.13.1. In the Algorithm 21.41, for each update operation, we need $O(k/\epsilon)$ time to maintain matrices V_1, V_2, V_3, and we need $\text{poly}(k/\epsilon)$ time to maintain tensor C. Thus the

Algorithm 21.41 Turnstile Frobenius Norm Low Rank Approximation Algorithm

procedure TURNSTILESTREAMING(k,$\mathcal{S}$)
  $s_1 \leftarrow s_2 \leftarrow s_3 \leftarrow O(k/\epsilon)$.
  Construct sketching matrices $S_i \in \mathbb{R}^{n^2 \times s_i}, \forall i \in [3]$ where entries of S_1, S_2, S_3 are w_1-wise independent random $N(0, 1/s_i)$ Gaussian variables.
  $t_1 \leftarrow t_2 \leftarrow t_3 \leftarrow \text{poly}(k/\epsilon)$.
  Construct sparse embedding matrices $T_i \in \mathbb{R}^{t_i \times n}, \forall i \in [3]$ where entries are w_2-wise independent.
  Initialize matrices:
  $V_i \leftarrow \{0\}^{n \times s_i}, \forall i \in [3]$.
  $C \leftarrow \{0\}^{t_1 \times t_2 \times t_3}$
  for $i \in [l]$ **do**
    Receive update operation $(x_i, y_i, z_i, \delta_i)$ from the data stream $\mathcal{S}$.
    for $r = 1 \rightarrow s_1$ **do**
      $(V_1)_{x_i,r} \leftarrow (V_1)_{x_i,r} + \delta_i \cdot (S_1)_{(y_i-1)n+z_i,r}$.
    end for
    for $r = 1 \rightarrow s_2$ **do**
      $(V_2)_{y_i,r} \leftarrow (V_2)_{y_i,r} + \delta_i \cdot (S_2)_{(z_i-1)n+x_i,r}$.
    end for
    for $r = 1 \rightarrow s_3$ **do**
      $(V_3)_{z_i,r} \leftarrow (V_3)_{z_i,r} + \delta_i \cdot (S_3)_{(x_i-1)n+y_i,r}$.
    end for
    for $r = 1 \rightarrow t_1, p = 1 \rightarrow t_2, q = 1 \rightarrow t_3$ **do**
      $C_{r,p,q} \leftarrow C_{r,p,q} + \delta_i \cdot (T_1)_{r,x_i}(T_2)_{p,y_i}(T_3)_{q,z_i}$.
    end for
  end for
  Compute $Y_1 \leftarrow T_1 V_1, Y_2 \leftarrow T_2 V_2, Y_3 \leftarrow T_3 V_3$.
  Compute $X_i^* \in \mathbb{R}^{s_i \times k}, \forall i \in [3]$ by solving
  $\min_{X_1,X_2,X_3} \|(Y_1 X_1) \otimes (Y_2 X_2) \otimes (Y_3 X_3) - C\|_F$
  Compute $U^* \leftarrow V_1 X_1^*, V^* \leftarrow V_2 X_2^*,\ W^* \leftarrow V_3 X_3^*$.
  return U^*, V^*, W^*
end procedure

update time is poly(k/ϵ). At the end of the stream, the time to compute

$$X_1^*, X_2^*, X_3^* = \arg\min_{X_1,X_2,X_3 \in \mathbb{R}^{O(k/\epsilon) \times k}} \left\| \sum_{j=1}^{k} (Y_1 X_1)_j \otimes (Y_2 X_2)_j \otimes (Y_3 X_3)_j - C \right\|_F ,$$

is exponential in poly(k/ϵ) running time since it should use a polynomial system solver. Instead of computing the rank-k solution, we can solve the following:

$$\alpha^* = \arg\min_{\alpha \in \mathbb{R}^{s_1 \times s_2 \times s_3}} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} \alpha_{i,j,l} \cdot (Y_1)_i \otimes (Y_2)_j \otimes (Y_3)_l - C \right\|_F$$

which will then give

$$\sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} \alpha^*_{i,j,l} \cdot (Y_1)_i \otimes (Y_2)_j \otimes (Y_3)_l$$

to be a rank-$O(k^3/\epsilon^3)$ bicriteria solution.

Further, similar to Theorem 21.4.8, we can solve

$$\min_{U \in \mathbb{R}^{n \times s_2 s_3}} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} U_{i+s_1(j-1)} \otimes (Y_2)_i \otimes (Y_3)_j - C \right\|_F$$

where $C = \sum_i A_i(I, T_2, T_3)$. Thus, we can obtain a rank-$O(k^2/\epsilon^2)$ in polynomial time.

Remark 21.13.2. If we choose $S_1, S_2, S_3, T_1, T_2, T_3$ to be random Cauchy matrices, then we are able to apply the entry-wise ℓ_1 norm low rank tensor approximation algorithm (see Theorem 21.7.14) in turnstile model.

21.14 Distributed Setting

Input data to large-scale machine learning and data mining tasks may be distributed across different machines. The communication cost becomes the major bottleneck of distributed protocols, and so there is a growing body of work on low rank matrix approximations in the distributed model [TD99, QOSG02, BCL05, BRB08, MBZ10, FEGK13, PMvdG+13, KVW14, BKLW14, BLS+16a, BWZ16, WZ16, SWZ17] and also many other machine learning problems such as clustering, boosting, and column subset selection [BBLM14, BLG+15, ABW17]. Thus, it is natural to ask whether our algorithm can be applied in the distributed setting. This section will discuss the distributed Frobenius norm low rank tensor approximation protocol in the so-called arbitrary-partition model (see, e.g. [KVW14, BWZ16]).

In the following, we extend the definition of the arbitrary-partition model [KVW14] to fit our tensor setting.

Definition 21.14.1 (Arbitrary-partition model [KVW14])**.** There are s machines, and the i^{th} machine holds a tensor $A_i \in \mathbb{R}^{n\times n\times n}$ as its local data tensor. The global data tensor is implicit and is denoted as $A = \sum_{i=1}^{s} A_i$. Then, we say that A is arbitrarily partitioned into s matrices distributed in the s machines. In addition, there is also a coordinator. In this model, the communication is only allowed between the machines and the coordinator. The total communication cost is the total number of words delivered between machines and the coordinator. Each word has $O(\log(sn))$ bits.

Now, let us introduce the distributed Frobenius norm low rank tensor approximation problem in the arbitrary partition model:

Definition 21.14.2 (Arbitrary-partition model Frobenius norm rank-k tensor approximation)**.** Tensor $A \in \mathbb{R}^{n\times n\times n}$ is arbitrarily partitioned into s matrices $A_1, A_2, \cdots, A_s$ distributed in s machines respectively, and $\forall i \in [s]$, each entry of A_i is at most $O(\log(sn))$ bits. Given tensor A, $k \in \mathbb{N}_+$ and an error parameter $0 < \epsilon < 1$, the goal is to find a distributed protocol in the model of Definition 21.15.1 such that

1. Upon termination, the protocol leaves three matrices $U^*, V^*, W^* \in \mathbb{R}^{n\times k}$ on the coordinator.

2. U^*, V^*, W^* satisfies that
$$\left\| \sum_{i=1}^{k} U_i^* \otimes V_i^* \otimes W_i^* - A \right\|_F^2 \leq (1+\epsilon) \min_{\text{rank}-k\ A'} \|A' - A\|_F^2.$$

3. The communication cost is as small as possible.

Theorem 21.14.1. *Suppose tensor $A \in \mathbb{R}^{n\times n\times n}$ is distributed in the arbitrary partition model (See Definition 21.15.1). There is a protocol(in Algorithm 21.43) which solves the problem in Definition 21.15.2 with constant success probability. In addition, the communication complexity of the protocol is $s(\mathrm{poly}(k/\epsilon) + O(kn))$ words.*

Proof. **Correctness.** The correctness is implied by Algorithm 21.2 and Algorithm 21.3 (Theorem 21.4.1.) Notice that $A_1 = \sum_{i=1}^{s} A_{i,1}, A_2 = \sum_{i=1}^{s} A_{i,2}, A_3 = \sum_{i=1}^{s} A_{i,3}$, which means that

$$Y_1 = T_1 A_1 S_1, Y_2 = T_2 A_2 S_2, Y_3 = T_3 A_3 S_3,$$

and

$$C = A(T_1, T_2, T_3).$$

According to line 23,

$$X_1^*, X_2^*, X_3^* = \arg\min_{X_1,X_2,X_3} \left\| \sum_{j=1}^{k} (Y_1X_1)_j \otimes (Y_2X_2)_j \otimes (Y_3X_3)_j - C \right\|_F .$$

According to Lemma 21.4.3, we have

$$\begin{aligned}
&\left\| \sum_{j=1}^{k} (T_1A_1S_1X_1^*)_j \otimes (T_2A_2S_2X_2^*)_j \otimes (T_3A_3S_3X_3^*)_j - A(T_1,T_2,T_3) \right\|_F^2 \\
\leq &(1+O(\epsilon)) \min_{X_1,X_2,X_3} \left\| \sum_{j=1}^{k} (A_1S_1X_1)_j \otimes (A_2S_2X_2)_j \otimes (A_3Y_3X_3)_j - A \right\|_F^2 \\
\leq &(1+O(\epsilon)) \min_{U,V,W} \left\| \sum_{i=1}^{k} U_i \otimes V_i \otimes W_i - A \right\|_F^2 ,
\end{aligned}$$

where the last inequality follows by the proof of Theorem 21.4.1. By scaling a constant of ϵ, we complete the proof of correctness.

Communication complexity. Since S_1, S_2, S_3 are w_1-wise independent, and T_1, T_2, T_3 are w_2-wise independent, the communication cost of sending random seeds in line 5 is $O(s(w_1+w_2))$ words, where $w_1 = O(k), w_2 = O(1)$ (see [KVW14, CW13, Woo14b, KN14]). The communication cost in line 18 is $s \cdot \mathrm{poly}(k/\epsilon)$ words due to $T_1A_{i,1}S_1, T_2A_{i,2}S_2, T_3A_{i,3}S_3 \in \mathbb{R}^{\mathrm{poly}(k/\epsilon)\times O(k/\epsilon)}$ and $C_i = A_i(T_1,T_2,T_3) \in \mathbb{R}^{\mathrm{poly}(k/\epsilon)\times\mathrm{poly}(k/\epsilon)\times\mathrm{poly}(k/\epsilon)}$.

Notice that, since $\forall i \in [s]$ each entry of A_i has at most $O(\log(sn))$ bits, each entry of Y_1, Y_2, Y_3, C has at most $O(\log(sn))$ bits. Due to Theorem 21.15.2, each entry of X_1^*, X_2^*, X_3^* has at most $O(\log(sn))$ bits, and the sizes of X_1^*, X_2^*, X_3^* are $\mathrm{poly}(k/\epsilon)$ words. Thus the communication cost in line 24 is $s \cdot \mathrm{poly}(k/\epsilon)$ words.

Finally, since $\forall i \in [s], U_i^*, V_i^*, W_i^* \in \mathbb{R}^{n\times k}$, the communication here is at most $O(skn)$ words. The total communication cost is $s(\mathrm{poly}(k/\epsilon) + O(kn))$ words. □

Remark 21.14.1. If we slightly change the goal in Definition 21.15.2 to the following: the coordinator does not need to output U^*, V^*, W^*, but each machine i holds U_i^*, V_i^*, W_i^* such that $U^* = \sum_{i=1}^s U_i^*, V^* = \sum_{i=1}^s V_i^*, W^* = \sum_{i=1}^s W_i^*$, then the protocol shown in Algorithm 21.43 does not have to do the line 28. Thus the total communication cost is at most $s \cdot \mathrm{poly}(k/\epsilon)$ words in this setting.

Remark 21.14.2. Algorithm 21.43 needs exponential in $\mathrm{poly}(k/\epsilon)$ running time since it solves a polynomial solver in line 23. Instead of solving line 23, we can solve the following optimization problem:

$$\alpha^* = \arg\min_{\alpha \in \mathbb{R}^{s_1 \times s_2 \times s_3}} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} \alpha_{i,j,l} \cdot (Y_1)_i \otimes (Y_2)_j \otimes (Y_3)_l - C \right\|_F .$$

Since it is actually a regression problem, it only takes polynomial running time to get α^*. And according to Lemma 21.4.5,

$$\sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} \alpha_{i,j,l}^* \cdot (Y_1)_i \otimes (Y_2)_j \otimes (Y_3)_l$$

gives a rank-$O(k^3/\epsilon^3)$ bicriteria solution.

Further, similar to Theorem 21.4.8, we can solve

$$\min_{U \in \mathbb{R}^{n \times s_2 s_3}} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} U_{i+s_1(j-1)} \otimes (Y_2)_i \otimes (Y_3)_j - C \right\|_F ,$$

where $C = \sum_i A_i(I, T_2, T_3)$. Thus, we can obtain a rank-$O(k^2/\epsilon^2)$ in polynomial time.

Remark 21.14.3. If we select sketching matrices $S_1, S_2, S_3, T_1, T_2, T_3$ to be random Cauchy matrices, then we are able to compute distributed entry-wise ℓ_1 norm rank-k tensor approximation (see Theorem 21.7.14). The communication cost is still $s(\mathrm{poly}(k/\epsilon) + O(kn))$ words. If we only require a bicriteria solution, then it only needs polynomial running time.

Using similar techniques as in the proof of Theorem 21.4.44, we can obtain:

Theorem 21.14.2. *Let* $\max_i\{t_i, d_i\} \leq n$. *Given a* $t_1 \times t_2 \times t_3$ *tensor* A *and three matrices: a* $t_1 \times d_1$ *matrix* T_1, *a* $t_2 \times d_2$ *matrix* T_2, *and a* $t_3 \times d_3$ *matrix* T_3. *For any* $\delta > 0$, *if there exists a solution to*

$$\min_{X_1,X_2,X_3} \left\| \sum_{i=1}^{k} (T_1X_1)_i \otimes (T_2X_2)_i \otimes (T_3X_3)_i - A \right\|_F^2 := \mathrm{OPT},$$

and each entry of X_i *can be expressed using* $O(\log n)$ *bits, then there exists an algorithm that takes* $\mathrm{poly}(\log n) \cdot 2^{O(d_1k+d_2k+d_3k)}$ *time and outputs three matrices:* $\widehat{X}_1$, $\widehat{X}_2$, *and* $\widehat{X}_3$ *such that* $\|(T_1\widehat{X}_1) \otimes (T_2\widehat{X}_2) \otimes (T_3\widehat{X}_3) - A\|_F^2 = \mathrm{OPT}$.

21.15 Distributed Setting

Input data to large-scale machine learning and data mining tasks may be distributed across different machines. The communication cost becomes the major bottleneck of distributed protocols, and so there is a growing body of work on low rank matrix approximations in the distributed model [TD99, QOSG02, BCL05, BRB08, MBZ10, FEGK13, PMvdG+13, KVW14, BKLW14, BLS+16a, BWZ16, WZ16, SWZ17] and also many other machine learning problems such as clustering, boosting, and column subset selection [BBLM14, BLG+15, ABW17]. Thus, it is natural to ask whether our algorithm can be applied in the distributed setting. This section will discuss the distributed Frobenius norm low rank tensor approximation protocol in the so-called arbitrary-partition model (see, e.g. [KVW14, BWZ16]).

In the following, we extend the definition of the arbitrary-partition model [KVW14] to fit our tensor setting.

Definition 21.15.1 (Arbitrary-partition model [KVW14])**.** There are s machines, and the i^{th} machine holds a tensor $A_i \in \mathbb{R}^{n\times n\times n}$ as its local data tensor. The global data tensor is implicit and is denoted as $A = \sum_{i=1}^{s} A_i$. Then, we say that A is arbitrarily partitioned into s matrices distributed in the s machines. In addition, there is also a coordinator. In this model, the communication is only allowed between the machines and the coordinator. The total communication cost is the total number of words delivered between machines and the coordinator. Each word has $O(\log(sn))$ bits.

Now, let us introduce the distributed Frobenius norm low rank tensor approximation problem in the arbitrary partition model:

Definition 21.15.2 (Arbitrary-partition model Frobenius norm rank-k tensor approximation)**.** Tensor $A \in \mathbb{R}^{n\times n\times n}$ is arbitrarily partitioned into s matrices $A_1, A_2, \cdots, A_s$ distributed in s machines respectively, and $\forall i \in [s]$, each entry of A_i is at most $O(\log(sn))$ bits. Given tensor A, $k \in \mathbb{N}_+$ and an error parameter $0 < \epsilon < 1$, the goal is to find a distributed protocol in the model of Definition 21.15.1 such that

1. Upon termination, the protocol leaves three matrices $U^*, V^*, W^* \in \mathbb{R}^{n\times k}$ on the coordinator.

2. U^*, V^*, W^* satisfies that

$$\left\| \sum_{i=1}^{k} U_i^* \otimes V_i^* \otimes W_i^* - A \right\|_F^2 \leq (1+\epsilon) \min_{\text{rank}-k\ A'} \|A' - A\|_F^2.$$

3. The communication cost is as small as possible.

Theorem 21.15.1. *Suppose tensor $A \in \mathbb{R}^{n\times n\times n}$ is distributed in the arbitrary partition model (See Definition 21.15.1). There is a protocol(in Algorithm 21.43) which solves the problem in Definition 21.15.2 with constant success probability. In addition, the communication complexity of the protocol is $s(\mathrm{poly}(k/\epsilon) + O(kn))$ words.*

Proof. **Correctness.** The correctness is implied by Algorithm 21.2 and Algorithm 21.3 (Theorem 21.4.1.) Notice that $A_1 = \sum_{i=1}^{s} A_{i,1}, A_2 = \sum_{i=1}^{s} A_{i,2}, A_3 = \sum_{i=1}^{s} A_{i,3}$, which means that

$$Y_1 = T_1 A_1 S_1, Y_2 = T_2 A_2 S_2, Y_3 = T_3 A_3 S_3,$$

and

$$C = A(T_1, T_2, T_3).$$

According to line 23,

$$X_1^*, X_2^*, X_3^* = \arg\min_{X_1,X_2,X_3} \left\| \sum_{j=1}^{k} (Y_1 X_1)_j \otimes (Y_2 X_2)_j \otimes (Y_3 X_3)_j - C \right\|_F.$$

According to Lemma 21.4.3, we have

$$\begin{aligned}
&\left\| \sum_{j=1}^{k} (T_1 A_1 S_1 X_1^*)_j \otimes (T_2 A_2 S_2 X_2^*)_j \otimes (T_3 A_3 S_3 X_3^*)_j - A(T_1, T_2, T_3) \right\|_F^2 \\
\leq & (1 + O(\epsilon)) \min_{X_1,X_2,X_3} \left\| \sum_{j=1}^{k} (A_1 S_1 X_1)_j \otimes (A_2 S_2 X_2)_j \otimes (A_3 Y_3 X_3)_j - A \right\|_F^2 \\
\leq & (1 + O(\epsilon)) \min_{U,V,W} \left\| \sum_{i=1}^{k} U_i \otimes V_i \otimes W_i - A \right\|_F^2,
\end{aligned}$$

where the last inequality follows by the proof of Theorem 21.4.1. By scaling a constant of ϵ, we complete the proof of correctness.

Communication complexity. Since S_1, S_2, S_3 are w_1-wise independent, and T_1, T_2, T_3 are w_2-wise independent, the communication cost of sending random seeds in line 5 is $O(s(w_1 + w_2))$ words, where $w_1 = O(k), w_2 = O(1)$ (see [KVW14, CW13, Woo14b, KN14]). The communication cost in line 18 is $s \cdot \text{poly}(k/\epsilon)$ words due to $T_1 A_{i,1} S_1, T_2 A_{i,2} S_2, T_3 A_{i,3} S_3 \in \mathbb{R}^{\text{poly}(k/\epsilon) \times O(k/\epsilon)}$ and $C_i = A_i(T_1, T_2, T_3) \in \mathbb{R}^{\text{poly}(k/\epsilon) \times \text{poly}(k/\epsilon) \times \text{poly}(k/\epsilon)}$.

Notice that, since $\forall i \in [s]$ each entry of A_i has at most $O(\log(sn))$ bits, each entry of Y_1, Y_2, Y_3, C has at most $O(\log(sn))$ bits. Due to Theorem 21.15.2, each entry of X_1^*, X_2^*, X_3^* has at most $O(\log(sn))$ bits, and the sizes of X_1^*, X_2^*, X_3^* are $\text{poly}(k/\epsilon)$ words. Thus the communication cost in line 24 is $s \cdot \text{poly}(k/\epsilon)$ words.

Finally, since $\forall i \in [s], U_i^*, V_i^*, W_i^* \in \mathbb{R}^{n \times k}$, the communication here is at most $O(skn)$ words. The total communication cost is $s(\text{poly}(k/\epsilon) + O(kn))$ words. □

Remark 21.15.1. If we slightly change the goal in Definition 21.15.2 to the following: the coordinator does not need to output U^*, V^*, W^*, but each machine i holds U_i^*, V_i^*, W_i^* such that $U^* = \sum_{i=1}^s U_i^*, V^* = \sum_{i=1}^s V_i^*, W^* = \sum_{i=1}^s W_i^*$, then the protocol shown in Algorithm 21.43 does not have to do the line 28. Thus the total communication cost is at most $s \cdot \text{poly}(k/\epsilon)$ words in this setting.

Remark 21.15.2. Algorithm 21.43 needs exponential in $\text{poly}(k/\epsilon)$ running time since it solves a polynomial solver in line 23. Instead of solving line 23, we can solve the following opti-

mization problem:

$$\alpha^* = \arg\min_{\alpha \in \mathbb{R}^{s_1 \times s_2 \times s_3}} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} \alpha_{i,j,l} \cdot (Y_1)_i \otimes (Y_2)_j \otimes (Y_3)_l - C \right\|_F .$$

Since it is actually a regression problem, it only takes polynomial running time to get α^*. And according to Lemma 21.4.5,

$$\sum_{i=1}^{s_1} \sum_{j=1}^{s_2} \sum_{l=1}^{s_3} \alpha^*_{i,j,l} \cdot (Y_1)_i \otimes (Y_2)_j \otimes (Y_3)_l$$

gives a rank-$O(k^3/\epsilon^3)$ bicriteria solution.

Further, similar to Theorem 21.4.8, we can solve

$$\min_{U \in \mathbb{R}^{n \times s_2 s_3}} \left\| \sum_{i=1}^{s_1} \sum_{j=1}^{s_2} U_{i+s_1(j-1)} \otimes (Y_2)_i \otimes (Y_3)_j - C \right\|_F ,$$

where $C = \sum_i A_i(I, T_2, T_3)$. Thus, we can obtain a rank-$O(k^2/\epsilon^2)$ in polynomial time.

Remark 21.15.3. If we select sketching matrices $S_1, S_2, S_3, T_1, T_2, T_3$ to be random Cauchy matrices, then we are able to compute distributed entry-wise ℓ_1 norm rank-k tensor approximation (see Theorem 21.7.14). The communication cost is still $s(\mathrm{poly}(k/\epsilon) + O(kn))$ words. If we only require a bicriteria solution, then it only needs polynomial running time.

Using similar techniques as in the proof of Theorem 21.4.44, we can obtain:

Theorem 21.15.2. *Let $\max_i\{t_i, d_i\} \leq n$. Given a $t_1 \times t_2 \times t_3$ tensor A and three matrices: a $t_1 \times d_1$ matrix T_1, a $t_2 \times d_2$ matrix T_2, and a $t_3 \times d_3$ matrix T_3. For any $\delta > 0$, if there exists a solution to*

$$\min_{X_1, X_2, X_3} \left\| \sum_{i=1}^{k} (T_1 X_1)_i \otimes (T_2 X_2)_i \otimes (T_3 X_3)_i - A \right\|_F^2 := \mathrm{OPT},$$

and each entry of X_i can be expressed using $O(\log n)$ bits, then there exists an algorithm that takes $\mathrm{poly}(\log n) \cdot 2^{O(d_1k+d_2k+d_3k)}$ time and outputs three matrices: $\widehat{X}_1$, $\widehat{X}_2$, and $\widehat{X}_3$ such that $\|(T_1\widehat{X}_1) \otimes (T_2\widehat{X}_2) \otimes (T_3\widehat{X}_3) - A\|_F^2 = \mathrm{OPT}$.

Chapter 22

Orthogonal Tensor Decomposition

A recent work [Wang, Tung, Smola, and Anandkumar, NIPS 2015] gives the fastest known algorithms for orthogonal tensor decomposition with provable guarantees. Their algorithm is based on computing sketches of the input tensor, which requires reading the entire input. We show in a number of cases one can achieve the same theoretical guarantees in sublinear time, i.e., even without reading most of the input tensor. Instead of using sketches to estimate inner products in tensor decomposition algorithms, we use importance sampling. To achieve sublinear time, we need to know the norms of tensor slices, and we show how to do this in a number of important cases. For symmetric tensors $A = \sum_{i=1}^{k} \lambda_i u_i^{\otimes p}$ with $\lambda_i > 0$ for all i, we estimate such norms in sublinear time whenever p is even. For the important case of $p = 3$ and small values of k, we can also estimate such norms. For asymmetric tensors sublinear time is not possible in general, but we show if the tensor slice norms are just slightly below $\|A\|_F$ then sublinear time is again possible. One of the main strengths of our work is empirical - in a number of cases our algorithm is orders of magnitude faster than existing methods with the same accuracy.

22.1 Introduction

Tensors are a powerful tool for dealing with multi-modal and multi-relational data. In recommendation systems, often using more than two attributes can lead to better recommendations. This could occur, for example, in Groupon where one could look at users, activities, and time (season, time of day, weekday/weekend, etc.), as three attributes to base predictions on (see [Moi14b] for a discussion). Similar to low rank matrix approximation, we seek a tensor decomposition to succinctly store the tensor and to apply it quickly. A popular decomposition method is the canonical polyadic decomposition, i.e., the CANDECOMP/PARAFAC (CP) decomposition, where the tensor is decomposed into a sum of rank-1 components [Har70]. We refer the reader to [WTSA15], where applications of CP including data mining, computational neuroscience, and statistical learning for latent variable models are mentioned.

A natural question, given the emergence of large data sets, is whether such decompositions can be performed quickly. There are a number of works on this topic [Tso10, PTC13, CV14, KPHF12, HNH+13, BS15, WLSH14]. Most related to ours are several recent works of Wang et al. [WTSA15] and Tung et al. [TWZS15], in which it is shown how to significantly speed up this decomposition for orthogonal tensor decomposition using the randomized technique of linear sketching [PP13]. In this work we also focus on orthogonal tensor decomposition. The idea in [WTSA15] is to create a succinct sketch of the input tensor, from which one can then perform implicit tensor decomposition by approximating inner products in existing decomposition methods.

Existing methods, like the power method, involve computing the inner product of a vector, which is now a rank-1 matrix, with another vector, which is now a slice of a

tensor. Such inner products can be approximated much faster by instead computing the inner product of the sketched vectors, which have significantly lower dimension. One can also replace the sketching with sampling to approximate inner products; we discuss some sampling schemes [Tso10, BS15] below and compare them to our work.

22.1.1 Our Contributions

We show in a number of important cases, one can achieve the same theoretical guarantees in the work of Wang et al. [WTSA15] (which was applied later by Tung et al. [TWZS15]), in *sublinear time*, that is, without reading most of the input tensor. While previous work needs to walk through the input at least once to create a sketch, we show one can instead perform *importance sampling* of the tensor based on the current iterate, together with reading a few entries of the tensor which help us learn the norms of tensor slices. We use a version of ℓ_2-sampling for our importance sampling. One source of speedup in our work and in Wang et al. [WTSA15] comes from approximating inner products in iterations in the robust tensor power method (see below). To estimate $\langle u, v\rangle$ for n-dimensional vectors u and v, their work computes sketches $S(u)$ and $S(v)$ and approximates $\langle u, v\rangle \approx \langle S(u), S(v)\rangle$. Instead, if one has u, one can sample coordinates i proportional to u_i^2, which is known as ℓ_2-sampling [MW10, CHW12]. One estimates $\langle u, v\rangle$ as $\frac{v_i\|u\|_2^2}{u_i}$, which is unbiased and has variance $O(\|u\|_2^2\|v\|_2^2)$. These guarantees are similar to those using sketching, though the constants are significantly smaller (see below), and unlike sketching, one does not need to read the entire tensor to perform such sampling.

Symmetric Tensors. As in [WTSA15], we focus on orthogonal tensor decomposition of symmetric tensors, though we explain the extension to the asymmetric case below. Symmetric tensors arise in engineering applications, for example, to represent the symmetric tensor field of stress, strain, and anisotropic conductivity. Another example is diffusion MRI in which one uses symmetric tensors to describe diffusion in the brain or other parts of the body. In spectral methods symmetric tensors are exactly those that come up in Latent

Dirichlet Allocation problems. Although one can symmetrize a tensor using simple matrix operations (see, e.g., [AGH+14]), we cannot do this in sublinear time.

In orthogonal tensor decompostion of a symmetric matrix, there is an underlying $n \times n \cdots n$ tensor $A^* = \sum_{i=1}^{k} \lambda_i v_i^{\otimes p}$, and the input tensor is $A = A^* + E$, where $\|E\|_2 \leq \epsilon$. We have $\lambda_1 > \lambda_2 > \cdots > \lambda_k > 0$ and that $\{v_i\}_{i=1}^{k}$ is a set of orthonormal vectors. The goal is to reconstruct approximations $\widehat{v}_i$ to the vectors v_i, and approximations $\widehat{\lambda}_i$ to the λ_i. Our results naturally generalize to tensors with different lengths in different dimensions. For simplicity, we first focus on order $p = 3$.

In the robust tensor power method [AGH+14], one generates a random initial vector u, and performs T update steps $\widehat{u} = A(I, u, u)/\|A(I, u, u)\|_2$, where

$$A(I, u, u) = \Big[\sum_{j=1}^{n}\sum_{\ell=1}^{n} A_{1,j,\ell}u_j u_\ell, \sum_{j=1}^{n}\sum_{\ell=1}^{n} A_{2,j,\ell}u_j u_\ell, \cdots, \sum_{j=1}^{n}\sum_{\ell=1}^{n} A_{n,j,\ell}u_j u_\ell\Big].$$

The matrices $A_{1,*,*}, \ldots, A_{n,*,*}$ are referred to as the slices. The vector $\widehat{u}$ typically converges to the top eigenvector in a small number of iterations, and one often chooses a small number L of random initial vectors to boost confidence. Successive eigenvectors can be found by deflation. The algorithm and analysis immediately extend to higher order tensors.

We use ℓ_2-sampling to estimate $A(I, u, u)$. To achieve the same guarantees as in [WTSA15], for typical settings of parameters (constant k and several eigenvalue assumptions) naïvely one needs to take $O(n^2)$ ℓ_2-samples from u *for each slice* in each iteration, resulting in $\Omega(n^3)$ time and destroying our sublinearity. We observe that if we additionally knew the squared norms $\|A_{1,*,*}\|_F^2, \ldots, \|A_{n,*,*}\|_F^2$, then we could take $O(n^2)$ ℓ_2-samples *in total*, where we take $\frac{\|A_{i,*,*}\|_F^2}{\|A\|_F^2} \cdot O(n^2)$ ℓ_2-samples from the i-th slice in expectation. Perhaps in some

applications such norms are known or cheap to compute in a single pass, but without further assumptions, how can one obtain such norms in sublinear time?

If A is a symmetric tensor, then $A_{j,j,j} = \sum_{i=1}^{k} \lambda_i v_{i,j}^3 + E_{j,j,j}$. Note that if there were no noise, then we could read off approximations to the slice norms, since $\|A_{j,*,*}\|_F^2 = \sum_{i=1}^{k} \lambda_i^2 v_{i,j}^2$, and so $A_{j,j,j}^{2/3}$ is an approximation to $\|A_{j,*,*}\|_F^2$ up to factors depending on k and the eigenvalues. However, there is indeed noise. To obtain non-trivial guarantees, the robust tensor power method assumes $\|E\|_2 = O(1/n)$, where

$$\|E\|_2 = \sup_{\|u\|_2=\|v\|_2=\|w\|_2=1} E(u,v,w) = \sup_{\|u\|_2=\|v\|_2=\|w\|_2=1} \sum_{i=1}^{n}\sum_{j=1}^{n}\sum_{k=1}^{n} E_{i,j,k} u_i v_j w_k,$$

which in particular implies $|E_{j,j,j}| = O(1/n)$. This assumption comes from the $\Theta(1/\sqrt{n})$-correlation of the random initial vector to v_1. This noise bound does not trivialize the problem; indeed, $E_{j,j,j}$ can be chosen adversarially subject to $|E_{j,j,j}| = O(1/n)$, and if the v_i were random unit vectors and the λ_i and k were constant, then $\sum_{i=1}^{k} \lambda_i v_{i,j}^3 = O(1/n^{3/2})$, which is small enough to be completely masked by the noise $E_{j,j,j}$. Nevertheless, there is a lot of information about the slice norms. Indeed, suppose $k = 1$, $\lambda_1 = \Theta(1)$, and $\|A\|_F = 1$. Then $A_{j,j,j} = \Theta(v_{1,j}^3) + E_{j,j,j}$, and one can show $\|A_{j,*,*}\|_F^2 = \lambda_1^2 v_{1,j}^2 \pm O(1/n)$. Again using that $|E_{j,j,j}| = O(1/n)$, this implies $\|A_{j,*,*}\|_F^2 = \omega(n^{-2/3})$ if and only if $A_{j,j,j} = \omega(1/n)$, and therefore one would notice this by reading $A_{j,j,j}$. There can only be $o(n^{2/3})$ slices j for which $\|A_{j,*,*}\|_F^2 = \omega(n^{-2/3})$, since $\|A\|_F^2 = 1$. Therefore, for each of them we can afford to take $O(n^2)$ ℓ_2-samples and still have an $O(n^{2+2/3}) = o(n^3)$ sublinear running time. The remaining slices all have $\|A_{j,*,*}\|_F^2 = O(n^{-2/3})$, and therefore if we also take $O(n^{1/3})$ ℓ_2-samples from *every slice*, we will also estimate the contribution to $A(I,u,u)$ from these slices well. This is also a sublinear $O(n^{2+1/3})$ number of samples.

While the previous paragraph illustrates the idea for $k = 1$, for $k = 2$ we need to read more than the $A_{j,j,j}$ entries to decide how many ℓ_2-samples to take from a slice. The analysis is more complicated because of *sign cancellations*. Even for $k = 2$ we could have $A_{j,j,j} = \lambda_1 v_{1,j}^3 + \lambda_2 v_{2,j}^3 + E_{j,j,j}$, and if $v_{1,j} = -v_{2,j}$ then we may not detect that $\|A_{j,*,*}\|_F^2$ is large. We fix this by also reading the entries $A_{i,j,j}, A_{j,i,j}$, and $A_{j,j,i}$ for every i and j. This is still only $O(n^2)$ entries and so we are still sublinear time. Without additional assumptions, we only give a formal analysis of this for $k \in \{1, 2\}$.

More importantly, if instead of third-order symmetric tensors we consider p-th order symmetric tensors for even p, we do not have such sign cancellations. In this case we do not have any restrictions on k for estimating slice norms. One does need to show after deflation, the slice norms can still be estimated; this holds because the eigenvectors and eigenvalues are estimated sufficiently well.

We also give several per-iteration optimizations of our algorithm, based on careful implementations of generating a sorted list of random numbers and random permutations. We find empirically (see below) that we are much faster per iteration than previous sketching algorithms, in addition to not having to read the entire input tensor in a preprocessing step.

Asymmetric Tensors: For asymmetric tensors, e.g., 3rd-order tensors of the form $\sum_{i=1}^k \lambda_i u_i \otimes v_i \otimes w_i$, it is impossible to achieve sublinear time in general, since it is hard to distinguish $A = e_i \otimes e_j \otimes e_k$ for random $i, j, k \in \{1, 2, \ldots, n\}$ from $A = 0^{\otimes 3}$. We make a necessary and sufficient assumption that all the entries of the u_i are less than $n^{-\gamma}$ for an arbitrarily small constant $\gamma > 0$. In this case, all slice norms are $o(n^{-\gamma})$ and by taking $O(n^{2-\gamma})$ samples from each slice we achieve sublinear time. We can also apply such an assumption to symmetric tensors.

Empirical Results. One of the main strengths of our work is our empirical results. In each iteration we approximate $A(I, u, u)$ a total of B times independently and take the median to increase our confidence. In the notation of [WTSA15], B corresponds to the number of independent sketches used. While the median works empirically, there are some theoretical issues with it discussed in Remark 22.3.1. Also let b be the total number of ℓ_2-samples we take per iteration, which corresponds to the sketch size in the notation of [WTSA15]. We found that empirically we can set B and b to be much smaller than that in [WTSA15] and achieve the same error guarantees. One explanation for this is that the variance bound we obtain via importance sampling is a factor of $4^3 = 64$ smaller than in [WTSA15], and for p-th order tensors, a factor of 4^p smaller.

To give an idea of how much smaller we can set b and B, to achieve roughly the same squared residual norm error on the synthetic data sets of dimension 1200 for finding a good rank-1 approximation, the algorithm of [WTSA15] would need to set parameters $b = 2^{16}$ and $B = 50$, whereas we can set $b = 10 \times 1200$ and $B = 5$. Our running time is 2.595 seconds and we have no preprocessing time, whereas the algorithm of [WTSA15] has a running time of 116.3 seconds and 55.34 seconds of preprocessing time. We refer the reader to Table 22.1 in Section 22.4. In total we are over 50 times faster.

We also demonstrate our algorithm in a real-world application using real datasets, even when the datasets are sparse. Namely, we consider a spectral algorithm for Latent Dirichlet Allocation [AGH+14, AFH+12] which uses tensor decomposition as its core computational step. We show a significant speedup can be achieved on tensors occurring in applications such as LDA, and we refer the reader to Table 22.2 in Section 22.4. For example, on the wiki [WTSA15] dataset with a tensor dimension of 200, we run more than 5

times faster than the sketching-based method.

Previous Sampling Algorithms. Previous sampling-based schemes of [Tso10, BS15] do not achieve our guarantees, because [Tso10] uses uniform sampling, which does not work for tensors with spiky elements, while the non-uniform sampling in [BS15] requires touching all of the entries in the tensor and making two passes over it.

22.2 Notation.

Let $[n]$ denote $\{1, 2, \ldots, n\}$. Let $\otimes$ denote the outer product, and $u^{\otimes 3} = u \otimes u \otimes u$. Let $A \in \mathbb{R}^{n^p}$, where p is the order of tensor A and n is the dimension of tensor A. Let $\langle A, B \rangle$ denote the entry-wise inner product between two tensors $A, B \in \mathbb{R}^{n^p}$, e.g., $\langle A, B \rangle = \sum_{i_1=1}^{n} \sum_{i_2=1}^{n} \cdots \sum_{i_p=1}^{n} A_{i_1,i_2,\cdots,i_p} \cdot B_{i_1,i_2,\cdots,i_p}$. For a tensor $A \in \mathbb{R}^{n^p}$,

$$\|A\|_F = \left(\sum_{i_1=1}^{n} \sum_{i_2=1}^{n} \cdots \sum_{i_p=1}^{n} A_{i_1,\cdots,i_p}^2 \right)^{\frac{1}{2}}.$$

For random variable X let $\mathbb{E}[X]$ denote its expectation of X and $\mathbb{V}[X]$ its variance (if these quantities exist).

For two functions f, g, we use the shorthand $f \lesssim g$ (resp. $\gtrsim$) to indicate that $f \leq Cg$ (resp. $\geq$) for some absolute constant C.

22.3 Main Results

We explain the details of our main results in this section. First, we state the importance sampling lemmas for our tensor application. Second, we explain how to quickly produce a list of random tuples according to a certain distribution needed by our algorithm. Third, we combine the first and the second parts to get a fast way of approximating tensor contractions, which are used as subroutines in each iteration of the robust tensor power method. We then provide our main theoretical results, and how to estimate the slice norms needed by our main algorithm.

Importance sampling lemmas. Approximating an inner product is a simple application of importance sampling. Tensor contraction $A(u, v, w)$ can be regarded as the inner product between two n^3-dimensional vectors, and thus importance sampling can be applied. Lemma 22.3.1 suggests that we can take a few samples according to their importance, e.g., we can sample $A_{i,j,k}u_iv_jw_k$ with probability $|u_iv_jw_k|^2/\|u\|_2^2\|v\|_2^2\|w\|_2^2$. As long as the number of samples is large enough, it will approximate the true tensor contraction $\sum_i \sum_j \sum_k A_{i,j,k}u_iv_jw_k$ with small variance after a final rescaling.

Lemma 22.3.1. Suppose random variable $X = A_{i_1,\cdots,i_p} \prod_{j=1}^p u_{j,i_j} / \prod_{j=1}^p q_{j,i_j}$ with probability $\prod_{j=1}^p q_{j,i_j}$ where $q_{j,i_j} = |u_{j,i_j}|^2/\|u_j\|_2^2, \forall j \in [n], \forall i_j \in [n]$, and we take L i.i.d. samples X, denote $X_1, X_2, \cdots, X_L$. Let $Y = \frac{1}{L}\sum_{\ell=1}^L X_\ell$. Then 1. $\mathbb{E}[Y] = \langle A, u_1 \otimes u_2 \otimes \cdots \otimes u_p \rangle$, and 2. $\mathbb{V}[Y] \leq \frac{1}{L}\|A\|_F^2 \cdot \|u_1 \otimes u_2 \otimes \cdots \otimes u_p\|_F^2$.

Similarly, we also have importance sampling for each slice $A_{i,*,*}$, i.e., "face" of A.

Lemma 22.3.2. For all $i_1 \in [n]$, suppose random variable $X^{i_1} = A_{i_1,i_2,\cdots,i_p} \prod_{j=2}^p u_{j,i_j} / \prod_{j=2}^p q_{j,i_j}$ with probability $\prod_{j=2}^p q_{j,i_j}$ where $q_{j,i_j} = |u_{j,i_j}|^2/\|u_j\|_2^2$, $\forall j \in \{2, 3, \cdots, n\}$, $\forall i_j \in [n]$ and we

take L_{i_1} i.i.d. samples of X^{i_1}, say $X_1^{i_1}, X_2^{i_1}, \cdots, X_L^{i_1}$. Let $Y^{i_1} = \frac{1}{L_{i_1}} \sum_{\ell=1}^{L} X_\ell^i$. Then 1. $\mathbb{E}[Y^i] = \langle A_{i_1,*,\cdots,*}, u_2 \otimes \cdots \otimes u_p \rangle$, and 2. $\mathbb{V}[Y^{i_1}] \leq \frac{1}{L_{i_1}} \|A_{i,*,\cdots,*}\|_F^2 \|u_2 \otimes \cdots \otimes u_p\|_F^2$.

Generating importance samples in linear time. We need an efficient way to sample indices of a vector based on their importance. We view this problem as follows: imagine $[0, 1]$ is divided into z "bins" with different lengths corresponding to the probability of selecting each bin, where z is the number of indices in a probability vector. We generate m random numbers uniformly from $[0, 1]$ and see which bin each random number belongs to. If a random number is in bin i, we sample the i-th index of a vector.

There are known algorithms [BP12, Wal77] to solve this problem in $O(z+m)$ time. We give an alternative algorithm GenRandTuples in Appendix 22.5. Our algorithm combines Bentley and Saxe's algorithm [BS80b] for efficiently generating m sorted random numbers in $O(m)$ time, and Knuth's shuffling algorithm [Knu69] for generating a random permutation of $[m]$ in $O(m)$ time. We use the notation CumProb(v, w) and CumProb(u, v, w) for the algorithm creating the distributions on $\mathbb{R}^{n^2}$ and $\mathbb{R}^{n^3}$ of Lemma 22.3.2 and Lemma 22.3.1, respectively. We note that naïvely applying previous algorithms would require $z = O(n^2)$ and $z = O(n^3)$ time to form these two distributions, but we can take $O(m)$ samples from them implicitly in $O(n + m)$ time.

Fast approximate tensor contractions. We propose a fast way to approximately compute tensor contractions $A(I, v, w)$ and $A(u, v, w)$ with a sublinear number of samples of A, as shown in Alogrithm 22.3 and Algorithm 22.4. Naïvely computing tensor contractions using all of the entries of A gives an exact answer but could take n^3 time. Also, to keep

our algorithm sublinear time, we never explicitly compute the deflated tensor; rather we represent it implicitly and sample from it.

The following theorem gives the error bounds of ApproxTIvw and ApproxTuvw (in Algorithm 22.3 and 22.4). Let $\widehat{b}_i$ be the number samples we take from slice $i \in [n]$ in ApproxTIvw, and let $\widehat{b}$ denote the total number of samples in our algorithm.

Theorem 22.3.3. For any $p \geq 3$, given tensor $A \in \mathbb{R}^{n^p}$, for any unit vector $u, v \in \mathbb{R}^n$, there is an algorithm that takes $\widehat{b}_i$ samples from i-th slice and it is able to output a value $\overline{A}(u, \cdots, u) \in \mathbb{R}$ and a vector $\overline{A}(I, u, \cdots, u) \in \mathbb{R}^n$ such that for any $b > 0$ if $\widehat{b}_i \geq b\|A_{i,*,\cdots,*}\|_F^2/\|A\|_F^2$ then the following bounds hold:

$$\mathbb{E}[\|\overline{E}(I, u, \cdots, u)\|_2^2] \leq n\|A\|_F^2/b, \text{ and } \mathbb{E}[|\overline{E}(u, \cdots, u)|^2] \leq \|A\|_F^2/b. \tag{22.1}$$

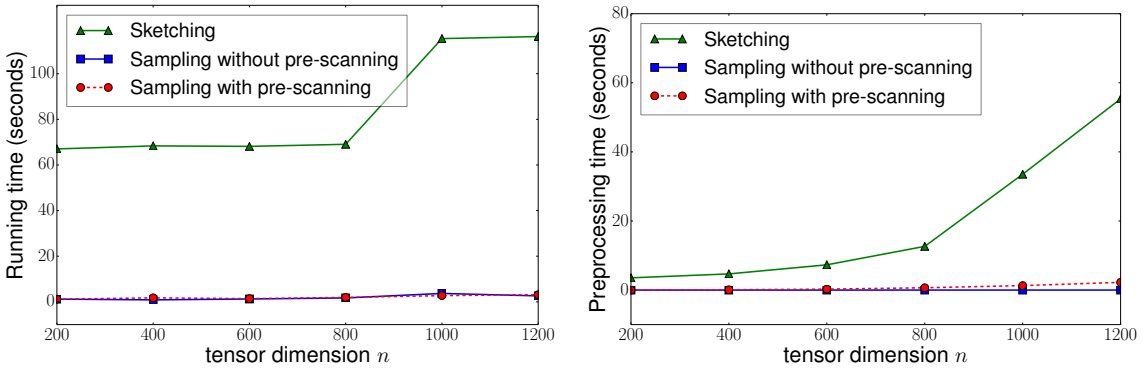
and

$$\mathbb{E}[|v^\top \overline{E}(I, u, \cdots, u)|^2] \leq \|A\|_F^2/b. \tag{22.2}$$

where $\overline{E} := \overline{A} - A$.

Eq. (22.2) can be obtained by observing that each random variable $[\overline{E}(I, u, \cdots, u)]_i$ is independent and so $\mathbb{E}[|v^\top \overline{E}(I, u, \cdots, u)|^2] = \sum_{i=1}^n v_i^2 \frac{\|A_{i,*,\cdots,*}\|_F^2}{\widehat{b}_i} \leq (\sum_{i=1}^n v_i^2)\frac{\|A\|_F^2}{b} = \frac{\|A\|_F^2}{b}$.

Remark 22.3.1. In [WTSA15], the coordinate-wise median of B estimates to the $A(I, v, w)$ is used to boost the success probability. There appears to be a gap [Wan16] in their argument as it is unclear how to achieve (22.2) after taking a coordinate-wise median, which is (7) in Theorem 1 of [WTSA15]. To fix this, we instead pay a factor proportional to the number of iterations in Algorithm 22.5 in the sample complexity $\widehat{b}$. Since we have expectation bounds on the quantities in Theorem 22.3.3, we can apply a Markov bound and a union bound across



(a) (b)

Figure 22.1: Sketching v.s. importance sampling. Running time with growing dimension

all iterations. This suffices for our main theorem concerning sublinear time below. One can obtain high probability bounds by running Algorithm 22.5 multiple times independently, and taking coordinate-wise medians of the output eigenvectors. Empirically, our algorithm works even if we take the median in each iteration, which is done in line 10 in Algorithm 22.3.

Replacing Theorem 1 in [WTSA15] by our Theorem 22.3.3, the rest of the analysis in [WTSA15] is unchanged. Our Algorithm 22.5 is the same as the sketching-based robust tensor power method in [WTSA15], except for lines 9, 11, 15, and 17, where the sketching-based approximate tensor contraction is replaced by our importance sampling procedures ApproxTuvw and ApproxTIvw. Rather than use Theorem 2 of Wang et al. [WTSA15], the main theorem concerning the correctness of the robust tensor decomposition algorithm, we use a recent improvement of it by Wang and Anandkumar in Theorems 4.1 and 4.2 of [WA16], which states general guarantees for any algorithm satisfying per iteration noise guarantees. These theorems also remove many of the earlier eigenvalue assumptions in Theorem 2 of [WTSA15].

We combine techniques from [WTSA15], [WA16] and [AGH+14] and extend the robust tensor power method analysis to any order $p \geq 3$.

Theorem 22.3.4. (Main, Abitrary order robust tensor power method) For any $p \geq 3$, $k \geq 1$, for any tensor $A = A^* + E \in \mathbb{R}^{n^p}$, where $A^* = \sum_{i=1}^k \lambda_i v_i^{\otimes p}$ with $\lambda_i > 0$ and orthonormal basis vectors $\{v_1, \ldots, v_k\} \subseteq \mathbb{R}^n$, $n \geq k$. Let λ_1, λ_k be the largest and smallest values in $\{\lambda_i\}_{i=1}^k$ and $\{\widehat{\lambda}_i, \widehat{v}_i\}_{i=1}^k$ be outputs of the robust tensor power method. For any sufficiently large constant $c_0 \geq 100$, there exists a sufficiently small constant $c > 0$, for any $\epsilon \in (0, c\lambda_k/(c_0 p^2 k n^{(p-2)/2})$ if E satisfies that

$$\|E\|_2 \leq \epsilon/(c_0\sqrt{n}) \tag{22.3}$$

and $T = \Omega(\log(\lambda_1 n/\epsilon)), L = \Omega(k\log(k))$, then with probability at least $9/10$, there exists a permutation $\pi : [k] \to [k]$, such that $\forall i \in [k]$,

$$|\lambda_i - \widehat{\lambda}_{\pi(i)}| \leq \epsilon, \quad \|v_i - \widehat{v}_{\pi(i)}\|_2 \leq \epsilon/\lambda_i. \tag{22.4}$$

Combining the previous theorem with our importance sampling analysis, we obtain:

Theorem 22.3.5 (Main, Sublinear time importance sampling robust tensor power method)**.** *Assume the notation of Theorem 22.3.4. For $p = 3$, there exists some sufficiently small constant $\gamma > 0$ such that $k \in [1, n^\gamma]$ and $\lambda_k \geq 1/n^\gamma$, then there exists some sufficiently small constant $\alpha \in (0, 1 - 10\gamma)$, if E satisfies (22.3), there exists an algorithm takes $O(n^{3-\alpha})$ time and uses $O(nk)$ space such that with probability $9/10$ the output $\widehat{\lambda}_i, \widehat{v}_i$ satisfies (22.4).*

Proof. For each $j \in [k]$, suppose we take $\widehat{b}^{(j)} = \sum_{i=1}^n \widehat{b}_i^{(j)}$ samples during the power iterations

for recovering $\widehat{\lambda}_j$ and $\widehat{v}_j$, the number of samples for slice i is

$$\widehat{b}_i^{(j)} \gtrsim b\|[A - \sum_{l=1}^{j-1} \widehat{\lambda}_l \widehat{v}_l^{\otimes 3}]_{i,*,*}\|_F^2 / \|A - \sum_{l=1}^{j-1} \widehat{\lambda}_l \widehat{v}_l^{\otimes 3}\|_F^2$$

where $b \gtrsim m \cdot n\|A\|_F^2/\epsilon^2$ and $m \geq k^2 LT$. Then the output guarantees of Theorem 22.3.4 hold for Algorithm 22.5 with constant probability. Our total time is $O(m\widehat{b})$ and the space is $O(nk)$, where $\widehat{b} = \max_{j\in[k]} \widehat{b}^{(j)}$. □

In Theorem 22.3.3, if we require $\widehat{b}_i = b\|A_{i,*,\cdots,*}\|_F^2/\|A\|_F^2$, we need to scan the entire tensor to compute $\|A_{i,*,\cdots,*}\|_F^2$, making our algorithm not sublinear. With the following mild assumption in Theorem 22.3.6, our algorithm is sublinear when sampling uniformly $(\widehat{b}_i = b/n)$ without computing $\|A_{i,*,\cdots,*}\|_F^2$:

Theorem 22.3.6 (Bounded slice norm). There exists a sufficiently small constant $\gamma > 0$ and a constant $\beta \in (0, 1]$, there exists a constant $\alpha > 0$(that depends on γ, β) such that for any order-p tensor $A = A^* + E \in \mathbb{R}^{n^p}$ with $\text{rank}(A^*) \leq n^\gamma$, $p \leq n^\gamma$, $\lambda_k \geq 1/n^\gamma$, $\|A_{i,*,\cdots,*}\|_F^2 \leq \frac{1}{n^\beta}\|A\|_F^2$ for all $i \in [n]$, and E satisfies (22.3), Algorithm 22.5 takes $O(n^{p-\alpha})$ time.

The condition $\alpha \in (0, 1]$ is a practical one. When $\alpha = 1$, all tensor slices have equal Frobenius norm. The case $\alpha = 0$ only occurs when $\|A_{i,*,\cdots,*}\|_F = \|A\|_F$; i.e., all except one slice is zero. This theorem can also be applied to asymmetric tensors, since the analysis in [WTSA15] can be extended to them.

For certain cases, we can remove the bounded slice norm assumption. The idea is to take a sublinear number of samples from the tensor to obtain upper bounds on all slice

norms. As outlined in Section 22.1, when p is even, because we do not have sign cancellations we can show:

Theorem 22.3.7 (Even order, informal of Theorem 22.9.14)**.** *There is a constant $\alpha > 0$ and a sufficiently small constant $\gamma > 0$, such that, for any even order-p tensor $A = A^* + E \in \mathbb{R}^{n^p}$ with $\text{rank}(A^*) \leq n^\gamma$, $p \leq n^\gamma$ and $\lambda_k \geq 1/n^\gamma$ and E satisfying (22.3), Algorithm 22.5 runs in $O(n^{p-\alpha})$ time.*

As outlined in Section 22.1, for $p = 3$ and small k we can take sign considerations into account:

Theorem 22.3.8 (Low rank)**.** *There is a constant $\alpha > 0$ such that for any symmetric tensor $A = A^* + E \in \mathbb{R}^{n^3}$ with E satisfying (22.3) and $\text{rank}(A^*) \leq 2$ and $\lambda_k \geq 1/n^\gamma$, Algorithm 22.5 runs in $O(n^{3-\alpha})$ time.*

22.4 Experiments

22.4.1 Experiment Setup and Datasets

Our implementation shares the same code base [1] as the sketching-based robust tensor power method proposed in [WTSA15]. We ran our experiments on an i7-5820k CPU with 64 GB of memory in single-threaded mode. We ran two versions of our algorithm: the version *with pre-scanning* scans the full tensor to accurately measure per-slice Frobenius norms and make samples for each slice in proportion to its Frobenius norm in ApproxTIvw; the version *without pre-scanning* assumes that the Frobenius norm of each slice is bounded by $\frac{1}{n^\alpha}\|A\|_F^2, \alpha \in (0, 1]$ and uses b/n samples per slice, where b is the total number of samples our algorithm makes, analogous to the sketch length b in [WTSA15].

Synthetic datasets. We first generated an orthonormal basis $\{v_i\}_{i=1}^k$ and then computed the synthetic tensor as $A^* = \sum_{i=1}^k \lambda_i v_i^{\otimes 3}$, with $\lambda_1 \geq \cdots \geq \lambda_k$. Then we normalized A^* such that $\|A^*\|_F = 1$, and added a symmetric Gaussian noise tensor E where $E_{ijl} \sim \mathcal{N}(0, \frac{\sigma}{n^{1.5}})$ for $i \leq j \leq l$. Then σ controls the noise-to-signal ratio and we kept it as 0.01 in all our synthetic tensors. For the eigenvalues λ_i, we generated three different decays: inverse decay $\lambda_i = \frac{1}{i}$, inverse square decay $\lambda_i = \frac{1}{i^2}$, and linear decay $\lambda_i = 1 - \frac{i-1}{k}$. We also set $k = 100$ when generating tensors, since higher rank eigenvalues were almost indistinguishable from the added noise. To show the scalability of our algorithm, we generated tensors with different dimensions: $n = 200, 400, 600, 800, 1000, 1200$.

[1] http://yining-wang.com/fftlda-code.zip

Real-life datasets. Latent Dirichlet Allocation [BNJ01] (LDA) is a powerful generative statistical model for topic modeling. A spectral method has been proposed to solve LDA models [AGH+14, AFH+12] and the most critical step in spectral LDA is to decompose a symmetric $K \times K \times K$ tensor with orthogonal eigenvectors, where K is the number of modeled topics. We followed the steps in [AGH+14, TWZS15] and built a $K \times K \times K$ tensor A_{LDA} for each dataset, and then ran our algorithms directly on A_{LDA} to see how it works on those tensors in real applications. In our experiments we keep $K = 200$. We used the two same datasets as the previous work [WTSA15]: Wiki and Enron, as well as four additional real-life datasets. We refer the reader to our GitHub repository [2] for our code and full results.

22.4.2 Results

We considered running time and the squared residual norm to evaluate the performance of our algorithms. Given a tensor $A \in \mathbb{R}^{n^3}$, let $\|A - \sum_{i=1}^{k} \lambda_i u_i \otimes v_i \otimes w_i\|_F^2$ denote the squared residual norm where $\{(\lambda_1, u_1, v_1, w_1), \cdots, (\lambda_k, u_k, v_k, w_k)\}$ are the eigenvalue/eigenvectors obtained by the robust power method. To reduce the experiment time we looked only for the first eigenvalue and eigenvector, but our algorithm is capable of finding any number of eigenvalues/eigenvectors. We list the pre-scanning time as preprocessing time in tables. It only depends on the tensor dimension n and unlike the sketching based method, it does not depend on b. Pre-scanning time is very short, because it only requires one pass of sequential access to the tensor which is very efficient on hardware.

Sublinear time verification. Our theoretical result suggests the total number of samples $b_{\text{no-prescan}}$ for our algorithm without pre-scanning is $n^{1-\alpha}(\alpha \in (0, 1])$ times larger than b_{prescan} for our algorithm with pre-scanning. But in experiments we observe that when $b_{\text{no-prescan}} = b_{\text{prescan}}$ both algorithms achieve very similar accuracy, indicating that in practice $\alpha \approx 1$.

Synthetic datasets. We ran our algorithm on a large number of synthetic tensors with different dimensions and different eigengaps. Table 22.1 shows results for a tensor with 1200 dimensions with 100 non-zero eigenvalues decaying as $\lambda_i = \frac{1}{i^2}$. To reach roughly the same residual norm, the running time of our algorithm is over 50 times faster than that of the sketching-based robust tensor power method, thanks to the fact that we usually need a relatively small B and b to get a good residual, and the hidden constant factor in running time of sampling is much smaller than that of sketching.

Our algorithm scales well on large tensors due to its sub-linear nature. In Figure 22.1(a), for the sketching-based method we kept $b = 2^{16}$, $B = 30$ for $n \leq 800$ and $B = 50$ for $n > 800$ (larger n requires more sketches to observe a reasonable recovery). For our algorithm, we chose b and B such that for each n, our residual norm is on-par or better than the sketching-based method. Our algorithm needs much less time than the sketching-based one over all dimensions. Another advantage of our algorithm is that there are zero or very minimal preprocessing steps. In Figure 22.1(b), we can see how the preprocessing time grows to prepare sketches when the dimension increases. For applications where only the first few eigenvectors are needed, the preprocessing time could be a large overhead.

Real-life datasets. Due to the small tensor dimension (200), our algorithm shows less speedup than the sketching-based method. But it is still $2 \sim 6$ times faster in each of the six real-life datasets, achieving the same squared residual norm. Table 22.2 reports results for one of the datasets in many different settings of (b, B). Like in synthetic datasets, we also empirically observe that the constant b in importance sampling is much smaller than the b used in sketching to get the same error guarantee.

Table 22.1: Synthetic tensor decomposition using the robust tensor power method. We use an order-3 normalized dense tensor with dimension $n = 1200$ with $\sigma = 0.01$ noise added. We run sketching-based and sampling-based methods to find the first eigenvalue and eigenvector by setting $L = 50$, $T = 30$ and varying B and b.

22.5 Generate importance sampling indices

In the section we present the full algorithm to generate importance sampling indices.

We view this problem as follows: imagine $[0, 1]$ is divided into n "bins" with different lengths corresponding to the probability of selecting each bin. We generate m random numbers uniformly from $[0, 1]$ and see which bin each random number belongs to. If a random number is in bin i, we sample the i-th index of a vector. There are two straightforward ways to generate such indices, but neither of them gives us linear running time in m and n. The first method is: (1) generate a list of random numbers (2) for each random number, choose

Table 22.2: Tensor decomposition in LDA on the wiki dataset. The tensor is generated by spectral LDA with dimension $200 \times 200 \times 200$. It is symmetric but not normalized. We fix $L = 50$, $T = 30$ and vary B and b.

the correct bin for it. Step (1) takes $O(m)$ time, but step (2) takes $O(mn)$ time in the worst case. The second method is: (1) generate a list of random numbers (2) sort these random numbers (3) sequentially for each random number, choose the correct bin for it. Step (1) takes $O(m)$ time, step (2) takes $O(m \log m)$ time, and step (3) takes $O(m + n)$ time as it merges two sorted lists.

In Algorithm 22.1, we instead present an $O(m+n)$ time algorithm which we call GenRandTuples for generating such indices by combining existing algorithms. We use Bentley and Saxe's algorithm GenSortedRandN(m) [BS80b] to efficiently generate m sorted random numbers(a) in $O(m)$ time. Then RandNToBins outputs a list of m indices(e) such

that for each random number in a, there is an index in $\widetilde{q}$. The running time of this step is $O(m+n)$. We use Knuth's shuffling algorithm GenRandPerm(m) [Knu69] to generate a random permutation of $[m]$(c) in $O(m)$ time. Finally, GenRandTuples generates m tuples with two (resp. three) entries given n probabilities in array $\widetilde{q}$ for computing $A(I, v, w)$ (resp. $A(u, v, w)$).

Claim 22.5.1. *Function* GenSortedRandN(m) *uses Bentley and Saxe's algorithm [BS80b] and takes* $O(m)$ *time to generate a list of random numbers between* 0 *and* 1 *in increasing order.*

Proof. For the correctness of this claim, we refer the reader to [BS80b]. □

Claim 22.5.2. *Function* RandNToBins(A, m, Q, n) *takes* $O(m+n)$ *time.*

Proof. The input of RandNToBins is two arrays, A and Q. The array A is a list of sorted random numbers in $[0, 1]$. The array Q can be thought as a list of boundary values for bins, e.g., if some entry x satisfies $Q[j] < x \leq Q[j+1]$, then we should assign x to bin j. This procedure is equivalent to merging two sorted lists. Thus, it takes linear time in the summation of two lengths. □

Claim 22.5.3. *Function* GenRandPerm(m) *uses Knuth's shuffle algorithm [Knu69] to generate a random permutation of* $[m]$ *in* $O(m)$ *time.*

Proof. For the correctness of this claim, we refer the reader to [Knu69] and [Wik16]. □

22.6 Importance sampling lemmas

In this section we state some useful facts and give proofs for some lemmas that are not proved in the main text.

We shall make use of the following facts which follow from the definitions of a tensor. The following facts hold immediately by the definition of a tensor's ℓ_2-norm and Frobenius norm.

Fact 22.6.1. *For any $p \geq 3$, for any tensor $A \in \mathbb{R}^{n^p}$ and p unit vectors $u_1, u_2, \cdots, u_p \in \mathbb{R}^n$,*

1. $\|u_1 \otimes u_2 \otimes \cdots \otimes u_p\|_F^2 = \prod_{j=1}^p \|u_j\|_2^2$.
2. $\langle A, u_1 \otimes \cdots \otimes u_p \rangle = \sum_{i_1=1}^n \cdots \sum_{i_p=1}^n A_{i_1,\cdots,i_p} \prod_{j=1}^p u_{j,i_j}$.
3. $\langle A_{i,*,\cdots,*}, u_2 \otimes \cdots \otimes u_p \rangle = \sum_{i_2=1}^n \cdots \sum_{i_p=1}^n A_{i,i_2,\cdots,i_p} \prod_{j=2}^p u_{j,i_j}$.

We provide the proofs for Lemma 22.3.1 and 22.3.2.

Lemma 22.3.1. Suppose random variable $X = A_{i_1,\cdots,i_p} \prod_{j=1}^p u_{j,i_j} / \prod_{j=1}^p q_{j,i_j}$ with probability $\prod_{j=1}^p q_{j,i_j}$ where $q_{j,i_j} = |u_{j,i_j}|^2 / \|u_j\|_2^2, \forall j \in [n], \forall i_j \in [n]$, and we take L i.i.d. samples X, denote $X_1, X_2, \cdots, X_L$. Let $Y = \frac{1}{L} \sum_{\ell=1}^L X_\ell$. Then 1. $\mathbb{E}[Y] = \langle A, u_1 \otimes u_2 \otimes \cdots \otimes u_p \rangle$, and 2. $\mathbb{V}[Y] \leq \frac{1}{L} \|A\|_F^2 \cdot \|u_1 \otimes u_2 \otimes \cdots \otimes u_p\|_F^2$.

Proof. Consider the expectation of Y,

$$\mathbb{E}[Y] = \mathbb{E}[\frac{1}{L} \sum_{\ell=1}^L X_\ell] = \mathbb{E}[X_\ell] = \sum_{i_1=1}^n \cdots \sum_{i_p=1}^n \left(A_{i_1,\cdots,i_p} \prod_{j=1}^p \frac{1}{q_{j,i_j}} u_{j,i_j} \right) \cdot \left(\prod_{j=1}^p q_{j,i_j} \right),$$

Furthermore, we can obtain,

$$\mathbb{E}[Y] = \sum_{i_1=1}^{n} \cdots \sum_{i_p=1}^{n} A_{i_1,\cdots,i_p} \prod_{j=1}^{p} u_{j,i_j} = \langle A, u_1 \otimes \cdots \otimes u_p \rangle.$$

It remains to upper bound the variance of Y,

$$\mathbb{V}[Y] = \mathbb{E}[Y^2] - (\mathbb{E}[Y])^2 = \mathbb{E}[\frac{1}{L^2}(\sum_{\ell=1}^{L} X_\ell)^2] - (\mathbb{E}[\frac{1}{L}\sum_{\ell=1}^{L} X_\ell])^2 = \frac{1}{L^2}(\mathbb{E}[(\sum_{\ell=1}^{L} X_\ell)^2] - L^2(\mathbb{E}[X_\ell])^2).$$

Furthermore, we can obtain,

$$\begin{aligned}
\mathbb{V}[Y] &= \frac{1}{L^2}\left(L\mathbb{E}[X_\ell^2] + L(L-1)\mathbb{E}[X_\ell]^2 - L^2\mathbb{E}[X_\ell]^2\right) \\
&\leq \frac{1}{L}\mathbb{E}[X_\ell^2] \\
&= \frac{1}{L}\left(\sum_{i_1=1}^{n} \cdots \sum_{i_p=1}^{n} A_{i_1,\cdots,i_p}^2 \left(\prod_{j=1}^{n} \frac{1}{q_{j,i_j}} u_{j,i_j}\right)^2 \left(\prod_{j=1}^{p} q_{j,i_j}\right)\right) \\
&= \frac{1}{L}\sum_{i_1=1}^{n} \cdots \sum_{i_p=1}^{n} A_{i_1,\cdots,i_p}^2 \prod_{j=1}^{p} \|u_j\|_2^2 \\
&\leq \frac{1}{L}\|A\|_F^2 \cdot \|u_1 \otimes \cdots \otimes u_p\|_F^2.
\end{aligned}$$

Thus, we complete the proof. □

Lemma 22.3.2. For all $i_1 \in [n]$, suppose random variable $X^{i_1} = A_{i_1,i_2,\cdots,i_p} \prod_{j=2}^{p} u_{j,i_j} / \prod_{j=2}^{p} q_{j,i_j}$ with probability $\prod_{j=2}^{p} q_{j,i_j}$ where $q_{j,i_j} = |u_{j,i_j}|^2/\|u_j\|_2^2$, $\forall j \in \{2,3,\cdots,n\}$, $\forall i_j \in [n]$ and we take L_{i_1} i.i.d. samples of X^{i_1}, say $X_1^{i_1}, X_2^{i_1}, \cdots, X_L^{i_1}$. Let $Y^{i_1} = \frac{1}{L_{i_1}} \sum_{\ell=1}^{L} X_\ell^i$. Then 1. $\mathbb{E}[Y^i] = \langle A_{i_1,*,\cdots,*}, u_2 \otimes \cdots \otimes u_p \rangle$, and 2. $\mathbb{V}[Y^{i_1}] \leq \frac{1}{L_{i_1}} \|A_{i,*,\cdots,*}\|_F^2 \|u_2 \otimes \cdots \otimes u_p\|_F^2$.

Proof. Consider the expectation of Y^{i_1},

$$\mathbb{E}[Y^{i_1}] = \mathbb{E}[\frac{1}{L}\sum_{\ell=1}^{L} X_\ell^{i_1}] = \mathbb{E}[X^{i_1}] = \sum_{i_2=1}^{n} \cdots \sum_{i_p=1}^{n} A_{i,j,k} \left(\prod_{j=2}^{p} \frac{1}{q_{j,i_j}} u_{j,i_j}\right) \left(\prod_{j=2}^{p} q_{j,i_j}\right),$$

Furthermore, we can obtain,

$$\mathbb{E}[Y^{i_1}] = \sum_{i_2=1}^{n} \cdots \sum_{i_p=1}^{n} A_{i_1,i_2,\cdots,i_p} \prod_{j=2}^{p} u_{j,i_j} = \langle A_{i_1,*,\cdots,*}, u_2 \otimes \cdots \otimes u_p \rangle.$$

Consider the variance of Y^{i_1},

$$\mathbb{V}[Y^{i_1}] = \mathbb{E}[(Y^{i_1})^2] - (\mathbb{E}[Y^{i_1}])^2 = \frac{1}{L^2}(L\mathbb{E}[(X^{i_1})^2] + L(L-1)(\mathbb{E}[X^{i_1}])^2) - (\mathbb{E}[X^{i_1}])^2.$$

Furthermore, we can obtain,

$$\begin{aligned}
\mathbb{V}[Y^{i_1}] &= \frac{1}{L}(\mathbb{E}[(X^{i_1})^2] - (\mathbb{E}[X^{i_1}])^2) \\
&\leq \frac{1}{L}\mathbb{E}[(X^{i_1})^2] \\
&= \frac{1}{L} \sum_{i_2=1}^{n} \cdots \sum_{i_p=1}^{n} A_{i_1,i_2,\cdots,i_p}^2 \left(\prod_{j=2}^{p} \frac{1}{q_{j,i_j}} u_{j,i_j} \right)^2 \left(\prod_{j=2}^{p} q_{j,i_j} \right) \\
&= \frac{1}{L} \sum_{i_2=1}^{n} \cdots \sum_{i_p=1}^{n} A_{i_1,i_2,\cdots,i_p}^2 \prod_{j=2}^{n} \|u_j\|_2^2 \\
&= \frac{1}{L} \|A_{i_1,*,\cdots,*}\|_F^2 \|u_2 \otimes \cdots \otimes u_p\|_F^2.
\end{aligned}$$

Thus, we complete the proof. □

22.7 Approximate Tensor Contractions

We need a slightly different version of Theorem 1 in [WTSA15]. Here we denote $\widehat{b}_i$ as the samples we take for tensor slice i.

Theorem 22.3.3. For any $p \geq 3$, given tensor $A \in \mathbb{R}^{n^p}$, for any unit vector $u, v \in \mathbb{R}^n$, there is an algorithm that takes $\widehat{b}_i$ samples from i-th slice and it is able to output a value $\overline{A}(u, \cdots, u) \in \mathbb{R}$ and a vector $\overline{A}(I, u, \cdots, u) \in \mathbb{R}^n$ such that for any $b > 0$ if $\widehat{b}_i \geq b\|A_{i,*,\cdots,*}\|_F^2/\|A\|_F^2$ then the following bounds hold:

$$\mathbb{E}[\|\overline{E}(I, u, \cdots, u)\|_2^2] \leq n\|A\|_F^2/b, \text{ and } \mathbb{E}[|\overline{E}(u, \cdots, u)|^2] \leq \|A\|_F^2/b. \tag{22.1}$$

and

$$\mathbb{E}[|v^\top \overline{E}(I, u, \cdots, u)|^2] \leq \|A\|_F^2/b. \tag{22.2}$$

where $\overline{E} := \overline{A} - A$.

Proof. **Part 1. of Equation 22.1**

By combining Lemma (22.3.2) and $\widehat{b}_i \geq b\|A_{i,*,\cdots,*}\|_F^2/\|A\|_F^2$, we know that

$$\mathbb{E}\left[|\overline{E}(I, u, \cdots, u)_i|^2\right] = \frac{\|A_{i,*,*}\|^2}{b\|A_{i,*,*}\|_F^2/\|A\|_F^2} = \|A\|_F^2/b.$$

Part 2 of Equation (22.1) It follows by Lemma 22.3.1.

Equation (22.2) It follows by

$$\begin{aligned}\mathbb{E}[|v^\top \overline{E}|^2] &= \mathbb{E}\left[\sum_{i=1}^{n} v_i^2 \overline{E}(I, u, \cdots, u)_i^2\right] \\ &\leq \sum_{i=1}^{n} v_i^2 \|A_{i,*,\cdots,*}\|_F^2 / \widehat{b}_i \\ &\leq \sum_{i=1}^{n} v_i^2 \|A\|_F^2 / b = \|A\|_F^2 / b.\end{aligned}$$

Thus, we complete the proof. □

Without loss of generality, we can assume that $\|A\|_F^2 = 1$. By choosing sufficiently large b, we can guarantee the error bounds of sketch noise $\overline{E}$ to be small.

Corollary 22.7.1. *For any $m \geq 3$, if $b \geq mnc_0^2/\epsilon^2$, for any unit vector $u, v \in \mathbb{R}^n$, then with probability at least $1 - 3/m$ such that,*

1. $\|\overline{E}(I, u, \cdots, u)\|_2 \leq \epsilon/c_0$.
2. $|\overline{E}(u, \cdots, u)| \leq \epsilon/(c_0\sqrt{n})$.
3. $|v^\top \overline{E}(I, u, \cdots, u)| \leq \epsilon/(c_0\sqrt{n})$.

Proof. **Part 1.** Using Markov's inequality $\Pr[x \geq a] \leq \mathbb{E}[x]/a$, we have

$$\Pr[\|\overline{E}(I, u, \cdots, u)\|_2^2 \geq (\epsilon/c_0)^2] \leq \frac{\mathbb{E}[\|\overline{E}(I, u, \cdots, u)\|_2^2]}{(\epsilon/c_0)^2} \leq \frac{n\|A\|_F^2/b}{(\epsilon/c_0)^2} \leq \frac{1}{m},$$

where the last step follows by choosing $b \geq mnc_0^2/\epsilon^2$.

Part 2. Similarly, by Markov's inequality, we have

$$\Pr[|\overline{E}(u, u, \cdots, u)|^2 \geq (\epsilon/(c_0\sqrt{n}))^2] \leq \frac{\mathbb{E}[\|\overline{E}(u, u, \cdots, u)\|_2^2]}{(\epsilon/(c_0\sqrt{n}))^2} \leq \frac{\|A\|_F^2/b}{(\epsilon/(c_0\sqrt{n}))^2} \leq \frac{1}{m},$$

where the last step also follows by choosing $b \geq mnc_0^2/\epsilon^2$.

Part 3. This part also can be proved by Markov's inequality and it requires $b \geq mnc_0^2/\epsilon^2$. □

If we compare our Theorem 22.3.3 to the bounds obtained by sketching in [WTSA15], we see that our expectation bounds for $\overline{E}(I, u, \cdots, u)$ and $\overline{E}(u, \cdots, u)$ are the same. As long as the conditions for Theorem 22.3.3 holds, all analysis in [WTSA15, WA16] will follow. To guarantee the noise introduced by sampling satisfies the bounds in Theorem 22.3.4, we require $b \geq n\|A\|_F^2/\epsilon^2 = O(n^2k)$.

However, as a condition of Theorem 22.3.3, we require that $\widehat{b_i} \gtrsim b\|A_{i,*,*}\|_F^2/\|A\|_F^2$. Because $\|A_{i,*,*}\|_F^2$ can be as large as $\|A\|_F^2$, if we made no assumptions, then $\widehat{b_i} \gtrsim b$; a summation over all n slices is $nb = O(n^3k)$, making our algorithm not sublinear time.

We will discuss how to deal with the term $\|A_{i,*,*}\|_F^2$ and make our algorithm run in sublinear time in the following paragraphs.

22.7.1 Case 1: sampling with known per-slice Frobenius norm

If we do not uniformly take $\widehat{b}_i \gtrsim b$ samples per slice, but sample based the Frobenius norm of each slice, in other words, the number of samples for slice i is exactly

$$\widehat{b}_i = b\frac{\|A_{i,*,*}\|_F^2}{\|A\|_F^2}$$

Then we will need only $\sum_{i=1}^n \widehat{b}_i = b = O(n^2)$ samples. However, to compute $\|A_{i,*,*}\|_F^2$, we have to *pre-scan* the tensor in $O(n^3)$ time.

Sometimes during the data collection process we can store the tensor's per-slice Frobenius norms as meta data and use them for free. But if we don't know the per-slice Frobenius norms, we have to compute them. This is not ideal because we need to scan the entire tensor before we start power iterations to compute per-slice Frobenius norms. Although in practice computing per-slice Frobenius norms only needs sequential access and can be quite efficient in memory or on storage device, it makes our algorithm depend on the full tensor and run in linear time. However, after making a weak assumption on the per-slice Frobenius norm which can be easily satisfied in practice, we can still obtain sublinear run time, as shown in Case 2.

22.7.2 Case 2: sampling without known per-slice Frobenius norm

Theorem 22.3.6 (Bounded slice norm). There exists a sufficiently small constant $\gamma > 0$ and a constant $\beta \in (0, 1]$, there exists a constant $\alpha > 0$(that depends on γ, β) such that for any order-p tensor $A = A^* + E \in \mathbb{R}^{n^p}$ with $\text{rank}(A^*) \leq n^\gamma$, $p \leq n^\gamma$, $\lambda_k \geq 1/n^\gamma$, $\|A_{i,*,\cdots,*}\|_F^2 \leq \frac{1}{n^\beta}\|A\|_F^2$ for all $i \in [n]$, and E satisfies (22.3), Algorithm 22.5 takes $O(n^{p-\alpha})$ time.

Proof. Because we assume $\|A_{i,*,*}\|_F^2 \leq \frac{1}{n^\alpha}\|A\|_F^2$, we can set $\widehat{b}_i = \frac{b}{n^\alpha} \gtrsim b\|A_{i,*,*}\|_F^2/\|A\|_F^2$ for all i such that the conditions for Theorem 22.3.3 hold. Thus, the number of samples we need is $\sum_{i=1}^n \widehat{b}_i = bn^{1-\alpha} = O(n^{3-\alpha})$.

□

We should note that the condition $0 < \alpha \leq 1$ is a very reasonable assumption. When $\alpha = 1$, all tensor slices have the equal Frobenius norm. The case where $\alpha = 0$ only occurs when $\|A_{i,*,*}\|_F = \|A\|_F$; in other words, all except one slices are zero. Except for this extreme case, our algorithm only needs to take $o(n^3)$ samples from the tensor.

Also, note that this proof does not make any assumption for the symmetry of the tensor. Thus, theorem 22.3.6 also applies to asymmetric tensors, as long as the analysis in [WTSA15] is extended to asymmetric case.

22.7.3 Case 3: improve the bounds in case 2

We are still interested in improve the $O(n^{3-\alpha})$ running time bound of our algorithm. We want to go one step further and remove the assumption on per-slice Frobenius norm. The basic idea is to take a sublinear number of samples from the tensor to estimate per-slice Frobenius norm. With some properties of the tensor (symmetry, low-rank, orthogonal, etc), achieving a sub-linear runtime bound is possible, as we will discuss below.

It is worth noting that in our experiments we have seen that sampling with or without known Frobenius norm (with or without pre-scanning) does not make a big difference for most datasets. Because sampling with known per-slice Frobenius norm is the best case ($\sum_{i=1}^{n} \widehat{b}_i = O(n^2)$), the algorithm described below with an improved bound on $\sum_{i=1}^{n} \widehat{b}_i = \omega(n^2)$ is unlikely to outperform. Thus, we did not conduct experiments on this part, and focus on theoretical discussions here.

22.8 Estimating Slice Norms in Sublinear Time

We present the following facts before introducing our lemmas and theorems:

22.8.1 Definitions and Facts

Fact 22.8.1. *For any symmetric matrix $A \in \mathbb{R}^{n \times n}$, $\|A\|_2 = \max_{\|u\|_2=1} |u^\top A u|$.*

Proof. Because A is symmetric, we choose S such that $S^\top S = A$,

$$\|A\|_2 = \|S\|_2^2 = \max_{\|u\|_2=1} \|Su\|_2^2 = \max_{\|u\|_2=1} |u^\top S^\top S u| = \max_{\|u\|_2=1} |u^\top A u|.$$

□

The following technical lemmas give necessary bounds on norms that we will use in proofs.

Lemma 22.8.2. *For any $E \in \mathbb{R}^{n^3}$, if $\|E\|_2 := \max_{\|u\|_2=\|v\|_2=\|w\|_2=1} |E(u,v,w)| \leq 1/n$, then for all $i \in [n]$,*

1. $\max_{\|u\|_2=1} \|E(I,u,u)\|_2 \leq \|E\|_2$,
2. $\|E_{i,*,*}\|_2 \leq 1/n$,
3. $\|E_{i,*,*}\|_F \leq 1/\sqrt{n}$,
4. $\forall j \in [n], |E_{i,j,j}| \leq 1/n$.

Proof. **Part 1.**

$$\begin{aligned}
\|E\|_2^2 = & \max_{\|u\|_2=\|v\|_2=\|w\|_2=1} |E(u,v,w)|^2 \\
= & \max_{\|u\|_2=\|v\|_2=\|w\|_2=1} \left(\sum_{i=1}^n u_i \cdot \sum_{j=1}^n \sum_{k=1}^n E_{i,j,k} v_j w_k \right)^2 \\
\geq & \max_{\|v\|_2=\|w\|_2=1} \sum_{i=1}^n u_i^2 \cdot \sum_{i=1}^n \left(\sum_{j=1}^n \sum_{k=1}^n E_{i,j,k} v_j w_k \right)^2 \\
= & \max_{\|v\|_2=\|w\|_2=1} \sum_{i=1}^n \left(\sum_{j=1}^n \sum_{k=1}^n E_{i,j,k} v_j w_k \right)^2 \\
\geq & \max_{\|v\|_2} \sum_{i=1}^n \left(\sum_{j=1}^n \sum_{k=1}^n E_{i,j,k} v_j v_k \right)^2 \\
= & \max_{\|v\|_2} \|E(I,v,v)\|_2^2
\end{aligned}$$

where the first inequality follows by setting $u_i = c \cdot \sum_{j=1}^n \sum_{k=1}^n E_{i,j,k} v_j v_k$, $\forall i \in [n]$ and $\sum_{i=1}^n u_i^2 = 1$, c is a normalizing constant.

Part 2. By definition of $\|\cdot\|_2$ for a tensor $E \in \mathbb{R}^{n^3}$, we have

$$\max_{\|u\|_2=1} \|E(I,u,u)\|_2 \leq \max_{\|u\|_2=\|v\|_2=\|w\|_2=1} |E(u,v,w)|$$

By definition of $E(I,u,u) \in \mathbb{R}^n$, we have

$$E(I,u,u)_i = \sum_{j=1}^n \sum_{k=1}^n E_{i,j,k} u_j u_k = u^\top E_{i,*,*} u$$

Thus, we can upper bound the $\|\cdot\|_2$ for matrix $E_{i,*,*} \in \mathbb{R}^{n^2}$ in the following sense,

$$\begin{aligned}
1/n &\geq \|E\|_2 \\
&\geq \max_{\|u\|_2=1} \|E(I,u,u)\|_2 \\
&= \max_{\|u\|_2=1} (\sum_{i=1}^{n} (u^\top E_{i,*,*} u)^2)^{1/2} \\
&\geq \max_{\|u\|_2=1} |u^\top E_{i,*,*} u| && \text{for any } i \in [n] \\
&= \|E_{i,*,*}\|_2, && \text{by Fact 22.8.1}
\end{aligned}$$

which completes the proof of Part 2.

Part 3. Since $\|E_{i,*,*}\|_2 \leq 1/n$ and the rank of $n \times n$ matrix is at most n, we have

$$\|E_{i,*,*}\|_F^2 = \mathbf{Tr}(E_{i,*,*}^\top E_{i,*,*}) = \sum_{j=1}^{n} \lambda_j \leq n \cdot \|E_{i,*,*}\|_2^2 \leq n \cdot (1/n)^2 \leq 1/n,$$

where λ_j are the eigenvalues of $E_{i,*,*}^\top E_{i,*,*}$ and the largest one is $\|E_{i,*,*}\|_2$, by the definition of $\|\cdot\|_2$ norm. The inequality implies $\|E_{i,*,*}\|_F \leq 1/\sqrt{n}$ and finishes the proof of Part 3.

Part 4. For each slice $i \in [n]$, by $\|E_{i,*,*}\|_2 \leq 1/n$ and definition of $\|\cdot\|_2$ of a matrix, we have $\max_{\|u\|_2=1} |u^\top E_{i,*,*} u| \leq 1/n$, choosing $u = e_j$ where e_j is the vector that jth position is 1 and all the other positions are 0. Thus, we know for any $j \in [n]$, $|E_{i,j,j}| \leq 1/n$. Thus, we complete the proof of Part 4.

□

Fact 22.8.3. *Given $p \geq 3$ and two vectors $u, v \in \mathbb{R}^n$ with $\|u\|_2 = \|v\|_2 = 1$, then*

1. $\|u^{\otimes p} - v^{\otimes p}\|_F \leq \sqrt{p}\|u - v\|_2$.
2. $|u_i - \widehat{u}_i| \leq \|u - v\|_2, \forall i \in [n]$.

3. $\|u_i \cdot u^{\otimes p-1} - \widehat{u}_i \cdot \widehat{u}^{\otimes p-1}\|_F \leq \sqrt{2p}\|u-v\|_2^2, \forall i \in [n]$.

Proof. We have $\|u\|_2 = \|v\|_2 = 1$, and $\|u-v\|_2^2 = \sum_{i=1}^n u_i^2 + v_i^2 - 2u_i v_i = \|u\|_2^2 + \|v\|_2^2 - 2\langle u, v\rangle$, putting it all together, we can get $\langle u, v\rangle = 1 - \frac{1}{2}\|u-v\|_2^2$. For any $p \geq 3$, we consider $\|u^{\otimes p} - v^{\otimes p}\|_F^2$,

$$\begin{aligned}
\|u^{\otimes p} - v^{\otimes p}\|_F^2 = & \sum_{i_1=1}^n \sum_{i_2=1}^n \cdots \sum_{i_p=1}^n (u_{i_1} u_{i_2} \cdots u_{i_p} - v_{i_1} v_{i_2} \cdots v_{i_p})^2 \\
= & \sum_{i_1=1}^n \sum_{i_2=1}^n \cdots \sum_{i_p=1}^n u_{i_1}^2 u_{i_2}^2 \cdots u_{i_p}^2 - 2u_{i_1} u_{i_2} \cdots u_{i_p} v_{i_1} v_{i_2} \cdots v_{i_p} + v_{i_1}^2 v_{i_2}^2 \cdots v_{i_p}^2 \\
= & (\|u\|_2^2)^p - 2(\langle u, v\rangle)^p + (\|v\|_2^2)^p \\
= & 2 - 2(\langle u, v\rangle)^p \\
= & 2 - 2\left(1 - \frac{1}{2}\|u-v\|_2^2\right)^p \\
\leq & p\|u-v\|_2^2
\end{aligned}$$

We can upper bound $\|u_i \cdot u^{\otimes p-1} - \widehat{u}_i \cdot \widehat{u}^{\otimes p-1}\|_F$,

$$\begin{aligned}
& \|u_i \cdot u^{\otimes p-1} - \widehat{u}_i \cdot \widehat{u}^{\otimes p-1}\|_F \\
\leq & \|u_i \cdot u^{\otimes p-1} - u_i \cdot \widehat{u}^{\otimes p-1}\|_F + \|u_i \cdot \widehat{u}^{\otimes p-1} - \widehat{u}_i \cdot \widehat{u}^{\otimes p-1}\|_F \\
= & |u_i| \cdot \|u^{\otimes p-1} - \widehat{u}^{\otimes p-1}\|_F + |u_i - \widehat{u}_i| \cdot \|\widehat{u}^{\otimes p-1}\|_F \\
\leq & 1 \cdot \sqrt{p-1}\|u-v\|_2 + \|u-v\|_2 \cdot 1 \\
\leq & \sqrt{2p}\|u-v\|_2.
\end{aligned}$$

□

Definition 22.8.1. For any $p \geq 3$, for any tensor $A \in \mathbb{R}^{n^p}$, we say vector $\tau \in \mathbb{R}^n$ is a "good"

estimate of A if for any $i \in [n]$,

$$\|A_{i,*,\cdots,*}\|_F^2 \leq \tau_i. \tag{22.5}$$

We say vector $\tau \in \mathbb{R}^n$ is an "efficient" estimate of A, if there exists some constant $\alpha > 0$ such that,

$$\sum_{i=1}^{n} \min(n^{p-1}\tau_i/\|A\|_F^2, n^{p-1}) = O(n^{p-\alpha}). \tag{22.6}$$

Remark 22.8.1. For $p = 3$, Equation (22.6) implies $\sum_{i=1}^{n} \widehat{b}_i = o(n^3)$ as long as we choose $\widehat{b}_i = \min(n^2\tau_i/\|A\|_F^2, n^2)$. Note that in the most part of this section, we focus on order $p = 3$ tensor.

22.8.2 Order $p = 3$, rank $k = 1$ tensor

We start by considering the simplest case, where the tensor A^* is assumed to be rank-1, $A^* = u^{\otimes 3}$. We can observe the true tensor plus some noise, i.e., $A = A^* + E$. As long as the noise E is sufficiently small, we can get a good bound on the tensor's per-slice Frobenius norm by just looking at its diagonals! The intuition is that Frobenious norm of slice i ($\|A_{i,*,*}\|_F^2$) is in proportional to u_i^2, and the diagonals of the tensor ($|A_{i,i,i}|$) is actually $|u_i|^3$, giving us an accurate estimate. We can choose per-slice samples $\widehat{b}_i$ accordingly. For those slices that potentially have $\|A_{i,*,*}\|_F \gtrsim 1/n^{1/3}$, to estimate the norm of that slice i, we *oversample* them by choosing all the n^2 samples of that $n \times n$ matrix $A_{i,*,*}$. Since we can show there are only $o(n)$ slices that have large estimates for $\|A_{i,*,*}\|_F$, then the total number of samples is $o(n^3)$, which is sublinear in the size of tensor A.

Lemma 22.8.4 (rank-1 tensor)**.** *There exists some constant $\alpha > 0$, for any tensor $A = E + u^{\otimes 3} \in \mathbb{R}^{n^3}$ with $\|u\|_2 = 1$,$\|E\|_2 \leq 1/n$. There exists an algorithm that takes $O(n^{3-\alpha})$ samples/time is able to output a vector $\tau \in \mathbb{R}^n$ which is a good and efficient estimate of A, i.e., τ, A satisfies (22.5) and (22.6).*

Proof. For each slice $i \in [n]$, we have $\|E_{i,*,*}\|_F \leq 1/\sqrt{n}$ (by part 3 of Lemma 22.8.2) and $\|A_{i,*,*}\|_F = \|E_{i,*,*} + u_i \cdot uu^\top\|_F$, which implies

$$|u_i| - 1/\sqrt{n} \leq \|A_{i,*,*}\|_F \leq |u_i| + 1/\sqrt{n}.$$

Also, observing the entries from main diagonal of tensor which is this form, $|A_{i,i,i}| = |E_{i,i,i} + u_i^3|$, using $|E_{i,i,i}| \leq 1/n$ (by part 4 of Lemma 22.8.2), we have

$$|u_i|^3 - 1/n \leq |A_{i,i,i}| \leq |u_i|^3 + 1/n.$$

If there is no noise, the diagonal term is exactly u_i^3, and we can get accurate $\|A_{i,*,*}\|_F = u_i^2$. However, consider the potential noise term, we have to discuss the following two cases:

Part 1. $|A_{i,i,i}| \geq 2/n$. In this case, $|u_i|^3 \geq 1/n$ and $\|A_{i,*,*}\|_F \geq |u_i| - 1/\sqrt{n} \geq 1/n^{1/3} - 1/\sqrt{n} \geq 1/(2n^{1/3})$. For such slice i, we need to take $\widehat{b}_i = O(n^2)$ examples to guarantee that the bounds on $|[\epsilon_{2,A}(u)]_i|$ and $\langle \omega, \epsilon_{2,A}(u) \rangle^2$ are enough.

Let S denote a set of indices such that, for each $i \in S$, $|A_{i,i,i}| \geq 2/n$. By triangle inequality, it means $|u_i|^3 \geq 1/n$ and then $|u_i| \geq 1/n^{1/3}$. We can show that $|S|$ is at most $n^{2/3}$, because u is a unit vector and there are at most $n^{2/3}$ coordinates i could have $|u_i| \geq 1/n^{1/3}$. Overall, the sample complexity for all these slices is $n^{3-1/3}$.

Part 2. $|A_{i,i,i}| < 2/n$. In this case, $\|A_{i,*,*}\|_F \leq |u_i| + 1/\sqrt{n} \leq 3/n^{1/3} + 1/\sqrt{n} \leq 4/n^{1/3}$. Thus, for such slice, we choose $\widehat{b}_i = O(b\|A_{i,*,*}\|_F^2/\|A\|_F^2) = O(b/n^{2/3})$ samples is sufficient for the error bounds. The number of such slice can be $O(n)$, thus the total number of samples for this part is $O(n^{3-2/3})$.

We set $\tau_i = 1$ for part 1 and $\tau_i = O(1/n^{2/3})$ for part 2.

□

Now we consider a further case with tensor rank $k = 2$. Because there are two distinct eigenvectors, the way of estimating $\|A_{i,*,*}\|_F$ becomes trickier. Besides the diagonal terms of the tensor, we also need to look at the diagonal terms of each tensor slice, $A_{i,j,j}$. Given parameters b, $\alpha \in (0,1)$ and tensor $A \in \mathbb{R}^{n^3}$, we use the sampling procedure in Algorithm 22.2.

22.8.3 Order $p = 3$, rank $k = 2$ tensor

Lemma 22.8.5 (rank-2 tensor)**.** *There exists some constant $\alpha > 0$, for any tensor $A = E + u^{\otimes 3} + v^{\otimes 3} \in \mathbb{R}^{n^3}$ with $\|u\|_2 = \|v\|_2 = 1$, $u \cdot v = 0$, $\|E\|_2 \leq 1/n$. There exists an algorithm that takes $O(n^{3-\alpha})$ samples/time is able to output a vector $\tau \in \mathbb{R}^n$ which is a good and efficient estimate of A with probability $1 - 1/\operatorname{poly}(n)$, i.e., τ, A satisfies (22.5) and (22.6).*

Proof. We assume that $A = E + u \otimes u \otimes u + v \otimes v \otimes v$. Note that we ignore the eigenvalues λ_1 and λ_2 because it will only be constants before $u \otimes u \otimes u$ and $v \otimes v \otimes v$ and our proof is unaffected.

Because vector $u \in \mathbb{R}^n$ is orthogonal to vector $v \in \mathbb{R}^n$, then

$$u^\top \cdot v = \sum_{i=1}^{n} u_i \cdot v_i = 0 \tag{22.7}$$

Consider the absolute value on main diagonal of tensor,

$$|A_{i,i,i}| \leq |E_{i,i,i}| + |u_i^3 + v_i^3| \leq 1/n + |u_i^3 + v_i^3|$$

where the first step follows by triangle inequality and the second step follows by Part 3 of Lemma 22.8.2 where $|E_{i,i,i}| \leq 1/n$. Now we start to prove the 4 parts of our procedure.

Part 1. Following the same reasoning in Lemma 22.8.4, for $|A_{i,i,i}| \geq 3/n$, either one of u_i^3 and v_i^3 is large or both u_i^3 and v_i^3 is large and have the same sign, both of these two situations imply that $\|A_{i,*,*}\|_F^2$ is large. Then we need to set $\tau_i = 1$ and take $\widehat{b}_i = O(n^2)$ samples for these slice. Also, the number of such slice is $O(n^{2/3})$ by using the similar argument in part 1 of Lemma 22.8.4. But unlike the rank-1 case, even if $|A_{i,i,i}| < 3/n$, we cannot conclude that $\|A_{i,*,*}\|_F^2$ is small (i.e., $\|A_{i,*,*}\|_F^2 \lesssim 1/n^{2/3}$), because u_i^3 and v_i^3 can have opposite sign and then cancel each other.

Part 2. For each $i \in [n]$, if $|A_{i,i,i}| < 3/n$, we take $O(b/n^\alpha)$ samples for slice i. By doing this, we can guarantee that the error bounds given by Equation (22.2) are sufficient for slice i as long as $\|A_{i,*,*}\|_F^2 \leq 5/n^\alpha$.

Now we need to handle the slice i where $\|A_{i,*,*}\|_F^2 > 5/n^\alpha$ but $|A_{i,i,i}| < 3/n$ in the next part.

Part 3. Let us consider slice $i \in [n]$ such that

$$\|A_{i,*,*}\|_F^2 = \|E_{i,*,*} + u_i \cdot uu^\top + v_i \cdot vv^\top\|_F^2 > 5/n^\alpha, \text{ and } |A_{i,i,i}| = |E_{i,i,i} + u_i^3 + v_i^3| < 3/n. \tag{22.8}$$

Using Part 3 and 4 of Lemma 22.8.2, we have

$$\|E_{i,*,*}\|_F^2 \leq 1/n, \text{ and } |E_{i,i,i}| \leq 1/n. \tag{22.9}$$

Combining Equation (22.8) and (22.9) with triangle inequality implies,

$$u_i^2 + v_i^2 > 4/n^\alpha, \text{ and } |u_i^3 + v_i^3| < 4/n.$$

Using $u_i^2 + v_i^2 > 4/n^\alpha$ we can obtain the following result,

$$\begin{aligned}
&\implies \text{either} \quad u_i^2 > 2/n^\alpha \quad \text{or } v_i^2 > 2/n^\alpha \\
&\implies \text{either} \quad |u_i| > 2/n^{\alpha/2} \quad \text{or } |v_i| > 2/n^{\alpha/2} \\
&\implies \text{either} \quad |u_i|^3 > 2/n^{3\alpha/2} \quad \text{or } |v_i|^3 > 2/n^{3\alpha/2}.
\end{aligned}$$

Note that $|u_i^3 + v_i^3| < 4/n$, $3\alpha/2 < 1$ and $\text{sign}(u_i) \neq \text{sign}(v_i)$, without loss of generality, assume $|u_i|^3 > 2/n^{3\alpha/2}$, then we have $|v_i|^3 > |u_i|^3 - |u_i^3 + v_i^3| > 2/n^{3\alpha/2} - 4/n > 1/n^{3\alpha/2}$. Therefore, we can obtain that

$$\text{both } |u_i|^3 > 1/n^{3\alpha/2} \text{ and } |v_i|^3 > 1/(n^{3\alpha/2}).$$

Thus, $|u_i v_i| > 1/n^\alpha$. Recall that the i is the index we choose at the beginning, and u, v are unit vectors, i.e.,$\|u\|_2 = \|v\|_2 = 1$.

Define set $S \subseteq [n]$, such that for any $j \in S$, $\text{sign}(u_j) = \text{sign}(v_j)$. Define $\overline{S} = [n] \backslash S$. By Equation (22.7),

$$0 = \sum_{j \in S} u_j v_j + \sum_{j' \in \overline{S}} u'_j v'_j$$

It is obvious that the i satisfying Equation (22.8) belongs to $\overline{S}$, then we can lower bound the contribution from set $\overline{S}$,

$$\left| \sum_{j' \in \overline{S}} u_{j'} v_{j'} \right| \geq |u_i v_i| + \left| \sum_{j' \in \overline{S} \backslash \{i\}} u_{j'} v_{j'} \right| > 1/n^\alpha$$

where the first step follows by triangle inequality and the second step follows by $|u_i v_i| > 1/n^\alpha$. Using triangle inequality again, we can also lower bound the contribution from set S, $|\sum_{j \in S} v_j u_j| > 1/n^\alpha$.

For any $j \in S$, $|u_j^3 + v_j^3| < 4/n$ and $\text{sign}(u_j) = \text{sign}(v_j)$. Then, $|u_j^3| < 4/n$ and $|v_j^3| < 4/n$, which implies $|u_j| < 2/n^{1/3}, |v_j| < 2/n^{1/3}$. Furthermore, we can obtain $|u_j \cdot v_j| < 4/n^{2/3}$, so we can lower bound the number of entries in set S,

$$|S| \geq \left| \sum_{j \in S} u_j v_j \right| / \left(\max_{j \in S} |u_j v_j| \right) > (1/n^\alpha)/(4/n^{2/3}) = n^{2/3-\alpha}/4.$$

If we take $\Theta(n^{1/3+\alpha} \log n)$ samples out of $[n]$ slices uniformly at random, then with probability $1 - 1/\operatorname{poly}(n)$, there exists at least one index j from set S. Since for all $j' \in S$, $\text{sign}(u_{j'}) = \text{sign}(v_{j'})$. Then u_j and v_j have the same sign. But set S is not good enough, because there is no lower bound for $|u_j v_j|$, for all $j \in S$. To remove this issue, we can remove the small entries from set S to obtain another set F.

Let $F \subseteq S$ denote the set of coordinates such that for any $j \in F$, $|u_j v_j| \geq 1/(2n^{1+\alpha})$. We can upper bound the contribution from set $S \backslash F$,

$$\left| \sum_{j \in S \backslash F} u_j v_j \right| = \sum_{j \in S \backslash F} |u_j v_j| \leq |S \backslash F| \cdot 1/(2n^{1+\alpha}) \leq n \cdot 1/(2n^{1+\alpha}) = 1/(2n^{\alpha}).$$

Thus using triangle inequality, we can lower bound the contribution from set F,

$$\left| \sum_{j \in F} u_j v_j \right| \geq \left| \sum_{j \in S} u_j v_j \right| - \left| \sum_{j \in S \backslash F} u_j v_j \right| \geq 1/n^{\alpha} - 1/(2n^{\alpha}) = 1/(2n^{\alpha}),$$

which implies,

$$|F| \geq \left| \sum_{j \in F} u_j v_j \right| / \left(\max_{j \in F} |u_j v_j| \right) > (1/2n^{\alpha})/(4/n^{2/3}) = n^{2/3-\alpha}/8.$$

Notice that $|F| \gtrsim |S|$, thus after taking $\Theta(n^{1/3+\alpha} \log n)$ samples over $[n]$, we still can hope to see one j from F. Now the idea is, we use index j to find out the large entry on diagonal of slice $A_{j,*,*}$. By doing this, we can recover some index l such that the norm of l-th slice is large, but $|A_{l,l,l}|$ looks small.

For each $j \in F$, let us look at the diagonal entry of slice $A_{j,*,*}$, consider entry $A_{j,l,l}$,

$$|A_{j,l,l}| = |E_{j,l,l} + u_j u_l^2 + v_j v_l^2|.$$

Because both $u_l^2 > 2/n^{\alpha}$ and $v_l^2 > 2/n^{\alpha}$, and either $|u_j| \geq 1/(2n^{1/2+\alpha/2})$ or $|v_j| \geq 1/(2n^{1/2+\alpha/2})$, then we have

$$|A_{j,l,l}| \geq |u_j u_l^2 + v_j v_l^2| - |E_{j,l,l}| \geq 1/n^{1/2+3\alpha/2} - 1/n \geq 1/(2n^{1/2+3\alpha/2}).$$

We need to show that $\|A_{j,*,*}\|_F^2$ is small. Since u_j and v_j have the same sign and $|A_{j,j,j}| \leq 3/n$, then $|u_j|^3 \leq 4/n$ which implies $|u_j|^2 \leq 4/n^{2/3}$. Thus $|u_j^2 + v_j^2| \leq 8/n^{2/3}$. Furthermore, we

have

$$\|A_{j,*,*}\|_F^2 \leq 2(\|E_{j,*,*}\|_F^2 + |u_j^2 + v_j^2|) \leq 2(1/n + 8/n^{2/3}) \leq 18/n^{2/3}.$$

Thus,

$$\{\#l \text{ such that } |A_{j,l,l}|^2 \geq 1/(4n^{1+3\alpha})\} \leq \frac{18/n^{2/3}}{1/(4n^{1+3\alpha})} = 72n^{1/3+3\alpha},$$

which means number of $|A_{j,l,l}|^2$ is at least $\Theta(1/n^{1+3\alpha})$ is at most $O(n^{1/3+3\alpha})$.

Part 4. We consider the i such that

$$\text{sign}(u_i) = \text{sign}(v_i) \text{ and } |A_{i,i,i}| = |E_{i,i,i} + u_i^3 + v_i^3| \geq 3/n.$$

Using $|E_{i,i,i}| \leq 1/n$, then we have either $|u_i| \geq 1/n^{1/3}$ or $|v_i| \geq 1/n^{1/3}$. Let us consider the jth diagonal entry of slice i (which is matrix $A_{i,*,*}$),

$$|A_{i,j,j}| = |E_{i,j,j} + u_i u_j^2 + v_i v_j^2|.$$

We want to recover the j such that

$$\|A_{j,*,*}\|_F^2 \geq 5/n^{\alpha}.$$

Then either $u_j^2 \geq 1/n^{\alpha}$ or $v_j^2 \geq 1/n^{\alpha}$. Then

$$|A_{i,j,j}| \geq |u_i u_j^2 + v_i v_j^2| - |E_{i,j,j}| \geq 1/n^{1/3+\alpha} - 1/n \geq 1/(2n^{1/3+\alpha}).$$

Thus, $|A_{i,j,j}|^2 \geq 1/(4n^{2/3+2\alpha})$. Because $\|A\|_F^2 = 1$, the total number of such entries over entire tensor is at most $O(n^{2/3+2\alpha})$.

Sample complexity. Overall the sample complexity over four parts is dominated by $n^{1-\alpha}$ and $n^{2/3+4\alpha}$. To minimize the sample complexity, we can set $1-\alpha = 2/3+4\alpha$ which implies $\alpha = 1/15$. Thus, the sample is $O(n^{3-1/15})$, which is sublinear in tensor size. □

For the rank-2 case, we may also want to recover the second eigenvalue and eigenvector. Because the recovered first eigenvalue $\widehat{\lambda}_1$ and eigenvector $\widehat{v}_1$ contain noise, we need to show that under this noise, the oversampling procedure still works.

Lemma 22.8.6 (Deflation for rank-2 tensor)**.** *Given tensor $A = E + (u^{\otimes 3} - \widehat{u}^{\otimes 3}) + v^{\otimes 3} \in \mathbb{R}^{n^3}$ where $\|u\|_2 = \|\widehat{u}\|_2 = \|v\|_2 = 1$, $\|u - \widehat{u}\|_2 \leq 1/\sqrt{n}$, $u \cdot v = 0$ and $\|E\| \leq 1/n$. There exists an algorithm that takes $O(n^{3-\alpha})$ samples/time is able to output a vector $\tau \in \mathbb{R}^n$ which is a good and efficient estimate of A with probability $1 - 1/\operatorname{poly}(n)$, i.e., τ, A satisfies (22.5) and (22.6).*

Proof. We use u_i to denote the i-th coordinate of vector $u \in \mathbb{R}^n$. Because $\|u - \widehat{u}\|_2 \leq 1/\sqrt{n}$, then for all $i \in [n]$, $|u_i - \widehat{u}_i| \leq 1/\sqrt{n}$. The proof sketch follows the proof of Lemma 22.8.4, we need to use the information from $|A_{i,i,i}|$ and $|A_{i,j,j}|$ to figure out if i-th slice has large Frobenius norm, for any $i, j \in [n]$, we have,

$$
\begin{aligned}
|A_{i,i,i}| &= |E_{i,i,i} + u_i^3 - \widehat{u}_i^3 + v_i^3|, && \text{where } |E_{i,i,i}| \leq 1/n, |u_i^3 - \widehat{u}_i^3| \leq 4/\sqrt{n}; \\
|A_{i,j,j}| &= |E_{i,j,j} + u_i u_j^2 - \widehat{u}_i \widehat{u}_j^2 + v_i v_j^2|, && \text{where } |E_{i,j,j}| \leq 1/n, |u_i u_j^2 - \widehat{u}_i \widehat{u}_j^2| \leq 2/\sqrt{n}.
\end{aligned}
$$

Consider the Frobenious norm of i-th slice, it can be written as

$$
\|A_{i,*,*}\|_F = \|E_{i,*,*} + (u_i \cdot uu^\top - \widehat{u}_i \cdot \widehat{u}\widehat{u}^\top) + v_i \cdot vv^\top\|_F,
$$

where $\|E_{i,*,*}\|_F \leq 1/\sqrt{n}$(by part 3 of Lemma 22.8.2) and $\|u_i \cdot uu^\top - \widehat{u}_i \cdot \widehat{u}\widehat{u}^\top\|_F \leq 3/\sqrt{n}$(by part 4 of Fact 22.8.3).

For any $\beta \in (0, 1)$, we use R to denote a set of indices such that $\{i \mid |u_i - \widehat{u}_i| >$

$1/n^{1/2+\beta/2}, i \in [n]\}$. Then we know that $|R| \leq n^{\beta}$, otherwise

$$\|u - \widehat{u}\|_2^2 = \sum_{i \in [n]} |u_i - \widehat{u}_i|^2 \geq \sum_{i \in R} |u_i - \widehat{u}_i|^2 > 1/n,$$

which is a contradiction to $\|u - \widehat{u}\|_2 \leq 1/\sqrt{n}$.

Part 1. Follow the similar reason in Lemma 22.8.4 and 22.8.5, for $|A_{i,i,i}| \geq 4/n$, then at least one of $u_i^3 - \widehat{u}_i^3$ and v_i^3 has large absolute value or both of them are large and have the same sign. Both of these two situations imply that $\|A_{i,*,*}\|_F^2$ is large. Then we need to set $\tau_i = 1$ and take $\widehat{b}_i = O(n^2)$ samples for each of these slices. Also, the number of such slice could have

$$\max(|u_i|, |v_i|, |\widehat{u}_i|) > 1/n^{1/3}$$

is $O(n^{2/3})$ by using the similar argument in part 1 of Lemma 22.8.4. Even if $|A_{i,i,i}| < 4/n$, we cannot conclude that $\|A_{i,*,*}\|_F^2$ is small, because $u_i^3 - \widehat{u}_i^3$ and v_i^3 can have opposite sign and then cancel each other.

Part 2. For each $i \in [n]$, if $|A_{i,i,i}| < 4/n$, we take $O(b/n^{\alpha})$ samples for slice i. By doing this, we can guarantee that the error bounds are sufficient for slice i as long as $\|A_{i,*,*}\|_F^2 \leq 5/n^{\alpha}$.

Now we need to handle the slice where $\|A_{i,*,*}\|_F^2 > 5/n^{\alpha}$ but $\|A_{i,i,i}| < 4/n$ in the next part.

Part 3.

Let us consider slice $i \in [n]$ such that

$$\|A_{i,*,*}\|_F^2 = \|E_{i,*,*} + u_i \cdot uu^{\top} - \widehat{u}_i \cdot \widehat{u}\widehat{u}^{\top} + v_i \cdot vv^{\top}\|_F^2 > 5/n^{\alpha}, \tag{22.10}$$

$$|A_{i,i,i}| = |E_{i,i,i} + u_i^3 - \widehat{u}_i^3 + v_i^3| < 3/n. \tag{22.11}$$

Using Part 3 and 4 of Lemma 22.8.2, we have

$$\|E_{i,*,*}\|_F^2 \leq 1/n, \text{ and } |E_{i,i,i}| \leq 1/n. \tag{22.12}$$

Combining Equation (22.10), (22.11), (22.12) and Fact 22.8.3 with triangle inequality implies,

$$\begin{aligned} 2v_i^2 &\geq 5/n^\alpha - 2\|E_{i,*,*}\|_F^2 - 2\|u_i \cdot uu^\top - \widehat{u}_i \cdot \widehat{u}\widehat{u}^\top\|_F^2 \\ &\geq 5/n^\alpha - 2/n - 2 \cdot 9/n \\ &\geq 4/n^\alpha \end{aligned}$$

and

$$|u_i^3 - \widehat{u}_i^3 + v_i^3| < 6/n.$$

Combining $\alpha \in (0, 2/3)$ with the above two equations, we can conclude that $\text{sign}(u_i - \widehat{u}_i) \neq \text{sign}(v_i)$, $|v_i|^3 > 1/n^{3\alpha/2}$ and $|u_i^3 - \widehat{u}_i^3| \geq 1/n^{3\alpha/2}$. As long as we choose $\alpha \in (0, 1/3)$, then it is impossible that

$$1/n^{3\alpha/2} \leq |u_i^3 - \widehat{u}_i^3| \leq 4/\sqrt{n}.$$

Thus, we know part 3 will never happen.

□

22.8.4 Even order tensor

In this section, we prove the even order case.

Lemma 22.8.7. *For any $E \in \mathbb{R}^{n^4}$ and any $\beta > 0$, if $\|E\|_2 := \max_{\|u\|_2=\|v\|_2=\|w\|_2=\|x\|_2} |E(u,v,w,x)| \leq 1/n^{1+\beta}$, then for all $i \in [n]$,*

1. $\max_{\|v\|_2=\|w\|_2=\|x\|_2=1} \|E(I,v,w,x)\|_2 \leq \|E\|_2$,
2. $\|E_{i,*,*,*}\|_2 \leq 1/n^{1+\beta}$,
3. $\|E_{i,*,*,*}\|_F \leq 1/\sqrt{n}$,
4. $\forall j \in [n], |E_{i,j,j,j}| \leq 1/n^{1+\beta}$.

Proof. **Part 1.**

$$\begin{aligned}
\|E\|_2^2 = & \max_{\|u\|_2=\|v\|_2=\|w\|_2=\|x\|_2=1} |E(u,v,w,x)|^2 \\
= & \max_{\|u\|_2=\|v\|_2=\|w\|_2=\|x\|_2=1} \left(\sum_{i=1}^n u_i \cdot \sum_{j=1}^n \sum_{k=1}^n E_{i,j,k,t} v_j w_k x_t \right)^2 \\
\geq & \max_{\|v\|_2=\|w\|_2=\|x\|_2=1} \sum_{i=1}^n u_i^2 \cdot \sum_{i=1}^n \left(\sum_{j=1}^n \sum_{k=1}^n E_{i,j,k,t} v_j w_k x_t \right)^2 \\
= & \max_{\|v\|_2=\|w\|_2=\|x\|_2=1} \sum_{i=1}^n \left(\sum_{j=1}^n \sum_{k=1}^n E_{i,j,k,t} v_j w_k x_t \right)^2 \\
= & \max_{\|v\|_2=\|w\|_2=\|x\|_2=1} \|E(I,v,w,x)\|_2^2,
\end{aligned}$$

where the first inequality follows by setting $u_i = c \cdot \sum_{j=1}^n \sum_{k=1}^n \sum_{t=1}^n E_{i,j,k,t} v_j v_k v_t$, $\forall i \in [n]$ and $\sum_{i=1}^n u_i^2 = 1$.

Part 2. By definition of $\|\cdot\|_2$ for a tensor $E \in \mathbb{R}^{n^4}$, we have

$$\max_{\|u\|_2=1} \|E(I,v,w,x)\|_2 \leq \max_{\|u\|_2=\|v\|_2=\|w\|_2=\|x\|_2=1} |E(u,v,w,x)|$$

By definition of $E(I,v,w,x) \in \mathbb{R}^n$, we have

$$E(I,v,w,x)_i = \sum_{j=1}^n \sum_{k=1}^n \sum_{t=1}^n E_{i,j,k,t} v_j w_k x_t.$$

Thus, we can upper bound the $\|\cdot\|_2$ for matrix $E_{i,*,*,*} \in \mathbb{R}^{n^3}$ in the following sense,

$$\begin{aligned}
1/n^{1+\beta} &\geq \|E\|_2 \\
&\geq \max_{\|v\|_2=\|w\|_2=\|x\|_2=1} \|E(I,v,w,x)\|_2 && \text{by Part 1.} \\
&= \max_{\|v\|_2=\|w\|_2=\|x\|_2=1} \left(\sum_{i=1}^n \left(\sum_{j=1}^n \sum_{k=1}^n \sum_{t=1}^n E_{i,j,k,t} v_j w_k x_t \right)^2 \right)^{1/2} \\
&\geq \max_{\|v\|_2=\|w\|_2=\|x\|_2=1} \left| \sum_{j=1}^n \sum_{k=1}^n \sum_{t=1}^n E_{i,j,k,t} v_j w_k x_t \right| \\
&= \|E_{i,*,*,*}\|_2, && \text{by Fact 22.8.1}
\end{aligned}$$

which completes the proof of Part 2.

Part 3. By the proof of Lemma 22.8.2, $\forall i,j \in [n]$ we have

$$\|E_{i,j,*,*}\|_2 \leq \|E_{i,*,*,*}\|_2 \leq 1/n^{1+\beta}.$$

Since $\|E_{i,j,*,*}\|_2 \leq 1/n^{1+\beta}$ and the rank of $n \times n$ matrix is at most n, thus,

$$\|E_{i,*,*,*}\|_F^2 = \sum_{j=1}^n \|E_{i,j,*,*}\|_F^2 \leq \sum_{j=1}^n n \cdot \|E_{i,j,*,*}\|_2^2 \leq n \cdot n \cdot (1/n^{1+\beta})^2 \leq 1/n^{2\beta},$$

which implies $\|E_{i,*,*,*}\|_F \leq 1/n^\beta$ and finishes the proof of Part 3.

Part 4. For each slice $i \in [n]$, by $\|E_{i,*,*,*}\|_2 \leq 1/n^{1+\beta}$ and definition of $\|\cdot\|_2$ of a matrix, we have

$$\max_{\|v\|_2=\|w\|_2=\|x\|_2=1} \left| \sum_{j=1}^{n} \sum_{k=1}^{n} \sum_{t=1}^{n} E_{i,j,k,t} v_j w_k x_t \right| \leq 1/n,$$

choosing $v = w = x = e_j$ where e_j is the vector that jth position is 1 and all the other positions are 0. Thus, we know for any $j \in [n]$, $|E_{i,j,j,j}| \leq 1/n^{1+\beta}$. Thus, we complete the proof of Part 4.

□

Lemma 22.8.8 (Order $p = 4$)**.** *For sufficiently small constant $\gamma > 0$, for arbitrarily small constant $\beta > 0$, for any $k \leq n^\gamma$, $t < k$, for any given tensor $A = E + \sum_{i=1}^{k} u_i^{\otimes 4} - \sum_{i=1}^{t} \widehat{u}_i^{\otimes 4} \in \mathbb{R}^{n^4}$ with $\|E\|_2 \leq 1/n^{1+\beta}$, $u_i \cdot u_j = 0, \forall i, j \in [k]$, $\|\widehat{u}_i - u_i\|_2 \leq 1/\sqrt{n}$, $\forall i \in [t]$. There exists an algorithm that takes $O(n^{4-2\beta})$ samples/time is able to output a vector $\tau \in \mathbb{R}^n$ which is a good and efficient estimate of A, i.e., τ, A satisfies (22.5) and (22.6).*

Proof. Let $A = E + \sum_{i=1}^{k} u_i^{\otimes 4} - \sum_{i=1}^{t} \widehat{u}_i^{\otimes 4}$. For any $j \in [n]$, we use $u_{i,j}$ to denote the j-th coordinate of vector $u_i \in \mathbb{R}^n$. We can observe the main diagonal of A,

$$|A_{j,j,j,j}| = \left| E_{j,j,j,j} + \sum_{i=1}^{t} (u_{i,j}^4 - \widehat{u}_{i,j}^4) + \sum_{i=t+1}^{k} u_{i,j}^4 \right|.$$

Since $\forall i \in [t]$, $\|u_i - \widehat{u}_i\|_2 \leq 1/\sqrt{n}$, then $\forall j \in [n]$, $|u_{i,j} - \widehat{u}_{i,j}| \leq 1/\sqrt{n}$. Furthermore, we have

$$|u_{i,j}^4 - \widehat{u}_{i,j}^4| = |(u_{i,j} - \widehat{u}_{i,j})(u_{i,j} + \widehat{u}_{i,j})(u_{i,j}^2 + \widehat{u}_{i,j}^2)| \leq 4/\sqrt{n}.$$

By part 4 of Lemma 22.8.7, we have $|E_{j,j,j,j}| \leq 1/n$. Because there is no cancellation in $|A_{j,j,j,j}|$ and $1/\sqrt{n} \gg 1/n$, we can use the same threshold $1/n$ as Lemma 22.8.4 again.

Part 1, $|A_{j,j,j,j}| \geq 1/n$. In this case, for $i \in \{t+1, t+2, \cdots, k\}$ one of $|u_{i,j}|$ is large and $\|A_{j,*,*,*}\|_F^2$ is also large. Let S denote a set of indices such that, for each $j \in S$, $|A_{j,j,j,j}| \geq 1/n$. We can show an upper bound for $|S|$. For each j, there must exists one $i > t$ such that $|u_{i,j}| \geq 1/(kn^{1/4}) = 1/n^{1/4-\gamma}$. There are at most k different i, for each i we know u_i is a unit vector and then there are at most $n^{1/2-2\gamma}$ coordinates j of vector u_i could have $|u_{i,j}| \geq 1/n^{1/4-\gamma}$. Thus $|S| \leq kn^{1/2-2\gamma} \leq n^{1/2-\gamma}$. For each $i \in S$, we take $O(n^3)$ samples from slice j. Then the total number of samples is $O(n^{3+1/2-\gamma})$.

Part 2, $|A_{j,j,j,j}| < 1/n$. In this case, we know there is no $i > t$ such that $|u_{i,j}| \geq 2/n^{1/4}$. We can upper bound $\|A_{j,*,*,*}\|_F$,

$$
\begin{aligned}
&\|A_{j,*,*,*}\|_F \\
&\leq \|E_{j,*,*,*}\|_F + \left\| \sum_{i=1}^{t} u_{i,j} \cdot u_i^{\otimes 3} - \widehat{u}_{i,j} \cdot \widehat{u}_i^{\otimes 3} \right\|_F + \left\| \sum_{i=t+1}^{k} u_{i,j} \cdot u_i^{\otimes 3} \right\|_F \\
&\leq \|E_{j,*,*,*}\|_F + \left\| \sum_{i=1}^{t} u_{i,j} \cdot u_i^{\otimes 3} - u_{i,j} \cdot \widehat{u}_i^{\otimes 3} \right\|_F + \left\| \sum_{i=1}^{t} u_{i,j} \cdot \widehat{u}_i^{\otimes 3} - \widehat{u}_{i,j} \cdot \widehat{u}_i^{\otimes 3} \right\|_F + \left\| \sum_{i=t+1}^{k} u_{i,j} \cdot u_i^{\otimes 3} \right\|_F \\
&\leq 1/n^{\beta} + k \cdot 3/\sqrt{n} + k \cdot 1/\sqrt{n} + k \cdot 2/n^{1/4} \\
&\leq 3/n^{\min(\beta, 1/4-\gamma)}
\end{aligned}
$$

where the bound of the second term in the third step follows by Fact 22.8.3.

Thus, as long as $\beta < 1/4-\gamma$, for each such slice i, we choose $\widehat{b}_i = O(b\|A_{j,*,*,*}\|_F^2/\|A\|_F^2) = O(b/n^{2\beta})$ samples. Notice that $b = O(n^3)$ in order 4 tensor. The number of such i can be $O(n)$, thus the total sample complexity is $n^{4-2\beta}$. □

We can extend Lemma 22.8.8 to general case where order p is even,

Theorem 22.8.9 (Even order)**.** *For sufficiently small constant $\gamma > 0$, there exists some constant $\alpha > 0$(depends on γ) for any $k \in [1, n^\gamma]$, $p \in [3, n^\gamma]$ $r < k$, for any given tensor $A = E + \sum_{i=1}^{k} \lambda_i u_i^{\otimes p} - \sum_{i=1}^{t} \widehat{\lambda}_i \widehat{u}_i^{\otimes p} \in \mathbb{R}^{n^p}$.*

For any sufficiently large constant $c_0 \geq 100$, there exists a sufficiently small constant $c > 0$, for any $\epsilon \in (0, c\lambda_k/(c_0 p^2 k n^{(p-2)/2})$ if E satisfies that $\|E\|_2 \leq \epsilon/(c_0\sqrt{n})$ and $\forall i \in [t]$.

$$|\widehat{\lambda}_i - \lambda_i| \leq \epsilon, \text{ and } \|\widehat{u}_i - u_i\|_2 \leq \epsilon/\lambda_i$$

There exists an algorithm that takes $O(n^{p-\alpha})$ samples/time is able to output a vector $\tau \in \mathbb{R}^n$ which is a good and efficient estimate of A, i.e., τ, A satisfies (22.5) and (22.6).

22.9 Robust Tensor Power Method Analysis for General Order $p \geq 3$

In Section 22.9.1, we extend several useful facts from 3rd order and 4th order to arbitrary p-th order tensor when $p \geq 3$. In Section 22.9.2, we extend analysis of the original robust tensor power method [AGH+14] from 3rd to arbitrary order $p \geq 3$, some of our proofs also borrow the idea from a very recent work [WA16].

22.9.1 Useful facts

Fact 22.9.1. *For any three unit vectors $u, v, w \in \mathbb{R}^n$, for any $0 \leq x \leq 1$, if $\langle u, w \rangle \geq 1 - x$ and $\langle v, w \rangle = 0$, then $\langle u, v \rangle \leq \sqrt{2x - x^2}$.*

Proof.

$$\begin{aligned}
\langle u, v \rangle =& \cos \theta(u, v) \\
\leq & |\cos \theta(u, w) \cos \theta(v, w)| + |\sin \theta(u, w) \sin \theta(v, w)| \\
\leq & 0 + \sqrt{1 - (1 - x)^2} \\
= & \sqrt{2x - x^2}.
\end{aligned}$$

□

Fact 22.9.2. *For any $E \in \mathbb{R}^{n^p}$, $u, v \in \mathbb{R}^n$, then $|v^\top E(I, u, \cdots, u)| = |E(v, u, \cdots, u)|$.*

Proof. It follows

$$\begin{aligned}|v^\top E(I,u,\cdots,u)| &= \left|\sum_{i_1=1}^n v_{i_1}\cdot\left(\sum_{i_2=1}^n\cdots\sum_{i_p=1}^n E_{i_1,i_2,\cdots,i_p}u_{i_2}\cdots u_{i_p}\right)\right| \\ &= \left|\sum_{i_1=1}^n\sum_{i_2=1}^n\cdots\sum_{i_p=1}^n E_{i_1,i_2,\cdots,i_p}v_{i_1}u_{i_2}\cdots u_{i_p}\right| \\ &= |E(v,u,\cdots,u)|.\end{aligned}$$

□

Fact 22.9.3. *For any $p \geq 3$, given orthogonal tensor $A^* = \sum_{i=1}^k \lambda_j v_j^{\otimes p} \in \mathbb{R}^{n^p}$ and vector $u \in \mathbb{R}^n$, for any $j \in [k]$, we have $|v_j^\top A^*(I,u,\cdots,u)| = \lambda_j |v_j^\top u|^{p-1}$.*

Proof. For any $j \in [k]$, we have

$$\begin{aligned}|v_j^\top A^*(I,u,\cdots,u)| &= \left|\sum_{i=1}^n v_{j,i}\sum_{\ell=1}^k \lambda_\ell v_{\ell,i}\sum_{i_2=1}^n\cdots\sum_{i_p=1}^n v_{\ell,i_2}\cdots v_{\ell,i_p}u_{i_2}\cdots u_{i_p}\right| \\ &= \left|\lambda_j\sum_{i_2=1}^n\cdots\sum_{i_p=1}^n v_{j,i_2}\cdots v_{j,i_p}u_{i_2}\cdots u_{i_p}\right| \\ &= |\lambda_j||v_j^\top u|^{p-1}.\end{aligned}$$

□

Fact 22.9.4. *For any tensor $E \in \mathbb{R}^{n^p}$, for any unit vectors $u, v \in \mathbb{R}^n$,*

1. $|E(u,v,\cdots,v)| \leq \|E\|_2$.
2. $\|E(I,v,\ldots,v)\|_2 \leq \sqrt{n}\|E\|_2$.

Proof. The part 1 trivially follows by definition of $\|E\|_2$. For part 2, we define a unit vector w to be $(1/\sqrt{n}, \cdots, 1/\sqrt{n})$,

$$\begin{aligned}
& \|E(I, v, \ldots, v)\|_2^2 \\
= & \sum_{i_1=1}^n \left(\sum_{i_2=1}^n \cdots \sum_{i_p=1}^n E_{i_1,i_2,\cdots,i_p} v_{i_2} \cdots v_{i_p} \right)^2 \\
= & n \sum_{i_1=1}^n \left(\sum_{i_2=1}^n \cdots \sum_{i_p=1}^n E_{i_1,i_2,\cdots,i_p} w_{i_1} v_{i_2} \cdots v_{i_p} \right)^2 \\
\leq & n \|E\|_2^2,
\end{aligned}$$

which implies $\|E(I, v, \cdots, v)\|_2 \leq \sqrt{n}\|E\|_2$. □

Fact 22.9.5. *For any $p \geq 3$, for any unit vectors $x, y, u, v \in \mathbb{R}^n$, we have*

1. $\|[x \otimes v^{\otimes(p-1)}](I, u, \cdots, u) - [y \otimes v^{\otimes(p-1)}](I, u, \cdots, u)\|_2 = |\langle u, v\rangle|^{p-1} \cdot \|x - y\|_2$.
2. $\forall j \in \{0, 1, \cdots, p-2\}$,

$$\begin{aligned}
& \|[v^{\otimes(1+j)} \otimes x \otimes v^{\otimes(p-2-j)}](I, u, \cdots, u) - [v^{\otimes(1+j)} \otimes y \otimes v^{\otimes(p-2-j)}](I, u, \cdots, u)\|_2 \\
\leq & |\langle u, v\rangle|^{p-2} \cdot \|x - y\|_2.
\end{aligned}$$

Proof. **Part 1.** We consider the i-th coordinate of vector $[x \otimes v^{\otimes(p-1)}](I, u, \cdots, u) \in \mathbb{R}^n$, it can be written as

$$x_i \sum_{i_2=1}^n \cdots \sum_{i_p=1}^n v_{i_2} \cdots v_{i_p} u_{i_2} \cdots u_{i_p} = x_i \sum_{i_2=1}^n v_{i_2} u_{i_2} \cdots \sum_{i_p=1}^n v_{i_p} u_{i_p} = x_i \langle v, u\rangle^{p-1}.$$

Thus,

$$\text{LHS}^2 = \sum_{i=1}^{n} (x_i \langle v, u \rangle^{p-1} - y_i \langle v, u \rangle^{p-1})^2 = \|x - y\|_2^2 \cdot |\langle v, u \rangle|^{2(p-1)}.$$

Part 2. We consider the i-th coordinate of vector $[v^{\otimes(1+j)} \otimes x \otimes v^{\otimes(p-2-j)}](I, u, \cdots, u) \in \mathbb{R}^n$, it can be written as $v_i \langle x, u \rangle \cdot \langle v, u \rangle^{p-2}$. Thus,

$$\text{LHS}^2 = \sum_{i=1}^{n} (v_i \langle x, u \rangle \langle v, u \rangle^{p-2} - v_i \langle y, u \rangle \langle v, u \rangle^{p-2})^2 = \langle x - y, u \rangle^2 \langle v, u \rangle^{2(p-2)} \leq \|x - y\|_2^2 \langle v, u \rangle^{2(p-2)}.$$

□

Fact 22.9.6. *For any two unit vectors u, v, if $\theta(u, v) \in (0, \pi/2)$, then $\|u - v\|_2 \leq \tan \theta(u, v)$.*

Proof. Because $\theta(u, v) \in (0, \pi/2)$, we have $\cos \theta(u, v) \in (0, 1)$. We use x to denote $\langle u, v \rangle$. We want to show $\|u - v\|_2^2 \leq \tan^2 \theta(u, v)$, which is equivalent to

$$\begin{aligned}
& 2 - 2x \leq \sin^2 \theta(u, v) / \cos^2 \theta(u, v) \\
\iff & 2 - 2x \leq 1 - x^2 / x^2 \\
\iff & 0 \leq (1 - x)(1 + x - 2x^2) \\
\iff & 0 \leq (1 - x)^2 (1 + 2x)
\end{aligned}$$

which always holds. Thus we complete the proof. □

Fact 22.9.7. *Given an orthonormal basis, $v_1, v_2, \cdots, v_n$. Let $V = (v_2, \cdots, v_n) \in \mathbb{R}^{n \times (n-1)}$ and $A^* = \sum_{i=1}^{k} \lambda_i v_i^{\otimes p}$. Then for any vector $u \in \mathbb{R}^n$, we have $\|V^\top A^*(I, u, \cdots, u)\|_2^2 = \sum_{j=2}^{k} \lambda_j^2 |v_j^\top u|^{2(p-1)}$.*

Proof.

$$
\begin{aligned}
& \|V^\top A^*(I, u, \cdots, u)\|_2^2 \\
= & \sum_{j=2}^{n} |v_j^\top A^*(I, u, \cdots, u)|^2 \\
= & \sum_{j=2}^{n} \left(\sum_{i=1}^{n} v_{j,i} A^*(I, u, \cdots, u)_i \right)^2 \\
= & \sum_{j=2}^{n} \left(\sum_{i=1}^{n} v_{j,i} \sum_{i_2=1}^{n} \cdots \sum_{i_p=1}^{n} A^*_{i,i_2,\cdots,i_p} u_{i_2} \cdots u_{i_p} \right)^2 \\
= & \sum_{j=2}^{n} \left(\sum_{i=1}^{n} v_{j,i} \sum_{i_2=1}^{n} \cdots \sum_{i_p=1}^{n} (\sum_{\ell=1}^{n} \lambda_\ell v_{\ell,i} v_{\ell,i_2} \cdots v_{\ell,i_p}) u_{i_2} \cdots u_{i_p} \right)^2 \qquad \text{by definition of } A^* \\
= & \sum_{j=2}^{n} \left(\sum_{\ell=1}^{k} \lambda_\ell \sum_{i=1}^{n} v_{j,i} v_{\ell,i} \sum_{i_2=1}^{n} \cdots \sum_{i_p=1}^{n} (v_{\ell,i_2} \cdots v_{\ell,i_p}) u_{i_2} \cdots u_{i_p} \right)^2 \\
= & \sum_{j=2}^{k} \left(\lambda_j \sum_{i_2=1}^{n} \cdots \sum_{i_p=1}^{n} (v_{j,i_2} \cdots v_{j,i_p}) u_{i_2} \cdots u_{i_p} \right)^2 \\
= & \sum_{j=2}^{k} \lambda_j^2 |v_j^\top u|^{2(p-1)}
\end{aligned}
$$

□

22.9.2 Convergence guarantee and deflation

Lemma 22.9.8 (Lemma C.1 and Corollary C.1 in [WA16]). *For any $t \in [k]$ and $\eta \in (0, 1/2)$. Let $\mathcal{U}$ denote a set of random Gaussian vectors in $\mathbb{R}^n$. If $|\mathcal{U}| = \Omega(k \log(1/\eta))$, then with probability at least $1 - \eta$ there exists a vector $u \in \mathcal{U}$ such that*

$$\max_{j \in [k] \setminus \{t\}} |v_j^\top u| \le \frac{1}{4} |v_t^\top u| \text{ and } |v_t^\top u| \ge 1/\sqrt{n}.$$

We generalize Lemma C.2 in [WA16] from $p = 3$ to arbitrary $p \ge 3$,

Lemma 22.9.9. *For sufficiently small constant $c > 0$, for any constant $c_0 \ge 1$, for any $p \ge 3$, for any tensor $A = A^* + \widetilde{E} \in \mathbb{R}^{n^p}$ with $A^* = \sum_{i=1}^k \lambda_i v_i^{\otimes p}$, let*

$$u_{t+1} = A(I, u_t, \cdots, u_t) / \|A(I, u_t, \cdots, u_t)\|_2.$$

For any $\epsilon \le c\lambda_1/(c_0 p^2 k n^{(p-2)/2})$, and unit vector $u_t \in \mathbb{R}^n$, if

$$\|\widetilde{E}(I, u_t, \cdots, u_t)\|_2 \le \begin{cases} 4p\epsilon & \text{if } |v_1^\top u_t| \le 1 - 1/(c_0^2 p^2 k^2) \\ 6\epsilon/c_0 & \text{otherwise} \end{cases}$$

and

$$|\widetilde{E}(v, u_t, \cdots, u_t)| \le \begin{cases} 4\epsilon/\sqrt{n} & \text{if } |v_1^\top u_t| \le 1 - 1/(c_0^2 p^2 k^2) \\ 6\epsilon/(c_0\sqrt{n}) & \text{otherwise} \end{cases}$$

then for any $t \in [T]$,

1. $$\tan\theta(v_1, u_{t+1}) \le \begin{cases} 0.8 \tan\theta(v_1, u_t) & \text{if } |v_1^\top u_t| \le 1 - 1/(c_0^2 p^2 k^2) \\ 0.8 \tan\theta(v_1, u_t) + 18\epsilon/(c_0\lambda_1) & \text{otherwise} \end{cases}$$

2. $\max_{j \in [k] \setminus \{1\}} \lambda_j |v_j^\top u_t|^{p-2} \le (1/4)\lambda_1 |v_1^\top u_t|^{p-2}$.

3. For any $j \in \{2, \cdots, k\}$,

$$|v_j^\top u_{t+1}|/|v_1^\top u_{t+1}| \leq \begin{cases} 0.8|v_j^\top u_t|/|v_1^\top u_t| & \text{if } |v_1^\top u_t| \leq 1 - 1/(c_0^2 p^2 k^2) \\ 0.8|v_j^\top u_t|/|v_1^\top u_t| + 18\epsilon/(c_0 \lambda_1 \sqrt{n}) & \text{otherwise} \end{cases}$$

Proof. **Part 1.** Let $V \in \mathbb{R}^{n \times (n-1)}$ denote an orthonormal basis of the complement of v_1, i.e., V is $(v_2, \cdots, v_k, \cdots, v_n)$ and let $\widetilde{E}_{u_t} = \widetilde{E}(I, u_t, \cdots, u_t) \in \mathbb{R}^n$. We can give an upper bound for $\tan\theta(v_1, u_{t+1})$,

$$\begin{aligned}
& \tan\theta(v_1, u_{t+1}) \\
= \; & \tan\theta(v_1, A(I, u_t, \cdots, u_t)/\|A(I, u_t, \cdots, u_t)\|_2) && \text{by definition of } u_{t+1} \\
= \; & \tan\theta(v_1, A(I, u_t, \cdots, u_t)) && \text{by definition of angle} \\
= \; & \tan\theta(v_1, A^*(I, u_t, \cdots, u_t) + \widetilde{E}(I, u_t, \cdots, u_t)) && \text{by } A = A^* + \widetilde{E} \in \mathbb{R}^{n^p} \\
= \; & \tan\theta(v_1, A^*(I, u_t, \cdots, u_t) + \widetilde{E}_{u_t}) && \text{by } \widetilde{E}_{u_t} := \widetilde{E}(I, u_t, \cdots, u_t) \in \mathbb{R}^n \\
= \; & \frac{\|V^\top [A^*(I, u_t, \cdots, u_t) + \widetilde{E}_{u_t}]\|_2}{|v_1^\top [A^*(I, u_t, \cdots, u_t) + \widetilde{E}_{u_t}]|} && \text{by definition of } \tan\theta \\
\leq \; & \frac{\|V^\top A^*(I, u_t, \cdots, u_t)\|_2 + \|V^\top \widetilde{E}_{u_t}\|_2}{|v_1^\top A^*(I, u_t, \cdots, u_t)| - |v_1^\top \widetilde{E}_{u_t}|}. && \text{by triangle inequality}
\end{aligned}$$

Using Fact 22.9.7, we have

$$\begin{aligned}
\|V^\top A^*(I, u_t, \cdots, u_t)\|_2^2 = & \sum_{j=2}^k \lambda_j^2 |v_j^\top u_t|^{2(p-1)} && (22.13) \\
\leq & \left(\max_{j \in [k] \setminus \{1\}} |\lambda_j|^2 |v_j^\top u_t|^{2(p-2)} \right) \cdot \left(\sum_{j=2}^k |v_j^\top u_t|^2 \right) && (22.14)
\end{aligned}$$

Putting it all together, we have

$$
\begin{aligned}
& \tan\theta(v_1, u_{t+1}) \\
\leq\ & \frac{\|V^\top A^*(I, u_t, \cdots, u_t)\|_2 + \|V^\top \widetilde{E}_{u_t}\|_2}{|v_1^\top A^*(I, u_t, \cdots, u_t)| - |v_1^\top \widetilde{E}_{u_t}|} \\
\leq\ & \tan\theta(v_1, u_t) \cdot \frac{(\|V^\top A^*(I, u_t, \cdots, u_t)\|_2 + \|V^\top \widetilde{E}_{u_t}\|_2)/\|V^\top u_t\|_2}{|v_1^\top A^*(I, u_t, \cdots, u_t)|/|v_1^\top u_t| - |v_1^\top \widetilde{E}_{u_t}|/|v_1^\top u_t|} \\
\leq\ & \tan\theta(v_1, u_t) \cdot \frac{\max_{j\in[k]\setminus\{1\}} \lambda_j |v_j^\top u_t|^{p-2} + \|V^\top \widetilde{E}_{u_t}\|_2/\|V^\top u_t\|_2}{|v_1^\top A^*(I, u_t, \cdots, u_t)|/|v_1^\top u_t| - |v_1^\top \widetilde{E}_{u_t}|/|v_1^\top u_t|} \\
\leq\ & \tan\theta(v_1, u_t) \cdot \frac{\max_{j\in[k]\setminus\{1\}} \lambda_j |v_j^\top u_t|^{p-2} + \|V^\top \widetilde{E}_{u_t}\|_2/\|V^\top u_t\|_2}{\lambda_1 |v_1^\top u_t|^{p-2} - |v_1^\top \widetilde{E}_{u_t}|/|v_1^\top u_t|} \\
\leq\ & \tan\theta(v_1, u_t) \cdot \frac{(1/4)\lambda_1 |v_1^\top u_t|^{p-2} + \|V^\top \widetilde{E}_{u_t}\|_2/\|V^\top u_t\|_2}{\lambda_1 |v_1^\top u_t|^{p-2} - |v_1^\top \widetilde{E}_{u_t}|/|v_1^\top u_t|} \\
\leq\ & \tan\theta(v_1, u_t) \cdot (1/4) \cdot \underbrace{\frac{1}{1 - |v_1^\top \widetilde{E}_{u_t}|/(\lambda_1 |v_1^\top u_t|^{p-1})}}_{A} \\
& + \underbrace{\frac{1}{1 - |v_1^\top \widetilde{E}_{u_t}|/(\lambda_1 |v_1^\top u_t|^{p-1})}}_{A} \cdot \underbrace{\frac{\|V^\top \widetilde{E}_{u_t}\|_2}{\lambda_1 |v_1^\top u_t|^{p-1}}}_{B} \\
=\ & \tan\theta(v_1, u_t) \cdot (1/4) \cdot A + A \cdot B
\end{aligned}
$$

where the second step follows from $\tan\theta(v_1, u_t) = \frac{\|V^\top u_t\|_2}{|v_1^\top u_t|}$, the third step follows from Equation (22.13), the forth step follows from Fact 22.9.3,

the fifth step follows from Part 2 of Lemma 22.9.9.

We show

Claim 22.9.10. *For any $t \in [T]$, $|v_1^\top u_0| \leq |v_1^\top u_t|$.*

Proof. By induction hypothesis, we assume there exists some sufficiently small constant $c > 0$

such that $\tan\theta(v_1, u_t) \le 0.8\tan\theta(v_1, u_{t-1}) + c$. Thus, we can show

$$\begin{aligned}
\tan\theta(v_1, u_t) &\le 0.8(0.8\tan\theta(v_1, u_{t-1}) + c) + c \\
&\le 0.8^t \tan\theta(v_1, u_0) + c\sum_{j=0}^{t-1} 0.8^j \\
&\le 0.8^t \tan\theta(v_1, u_0) + 5c \\
&\le \tan\theta(v_1, u_0) && \text{by } \tan\theta(v_1, u_0) = \omega(1)
\end{aligned}$$

which implies $\theta(v_1, u_t) \le \theta(v_1, u_0)$ and hence $|v_1^\top u_t| = \cos\theta(v_1, u_t) \ge \cos\theta(v_1, u_0) = |v_1^\top u_0|$.

□

Then we can upper bound A and B

Claim 22.9.11. $A \le 1.1$.

Proof. Note that $|\widetilde{E}(v_j, u_t, \cdots, u_t)| = |v_j^\top \widetilde{E}(I, u_t, \cdots, u_t)| = |v_j^\top \widetilde{E}_{u_t}|$. Because

$$\begin{aligned}
|\widetilde{E}(v_j, u_t, \cdots, u_t)| &\le 4\epsilon/\sqrt{n} \\
&\le 4c\lambda_1/n^{(p-1)/2} && \text{by } \epsilon \le c\lambda_1/n^{(p-2)/2} \\
&\le 4c\lambda_1|v_1^\top u_0|^{p-1} && \text{by } |v_1^\top u_0| \ge 1/\sqrt{n}.
\end{aligned}$$

Thus, if we choose sufficiently small $c < 1/40$, using $|v_1^\top \widetilde{E}_{u_t}| \le \lambda_1|v_1^\top u_0|^{p-1}/10$ and $|v_1^\top u_0| \le |v_1^\top u_t|$, we can show

$$|v_1^\top \widetilde{E}_{u_t}| \le \lambda_1|v_1^\top u_0|^{p-1}/10 \le \lambda_1|v_1^\top u_t|^{p-1}/10$$

Thus, $A \le \frac{1}{1-1/11} = 1.1$ □

It remains to bound B. We give a proof by considering two cases separately, one is $|v_1^\top u_t| \le 1 - \frac{1}{c_0^2 p^2 k^2}$ and the other is $|v_1^\top u_t| > 1 - \frac{1}{c_0^2 p^2 k^2}$. If $|v_1^\top u_t| \le (1 - \frac{1}{c_0^2 p^2 k^2})$, we have

$$\begin{aligned}
B = & \frac{\|V^\top \widetilde{E}_{u_t}\|_2}{\lambda_1 |v_1^\top u_t|^{p-1}} \\
= & \frac{\sqrt{1-|v_1^\top u_t|^2}}{|v_1^\top u_t|} \cdot \frac{\|V^\top \widetilde{E}_{u_t}\|_2}{\lambda_1 |v_1^\top u_t|^{p-2}\sqrt{1-|v_1^\top u_t|^2}} \\
= & \tan\theta(v_1, u_t) \cdot \frac{\|V^\top \widetilde{E}_{u_t}\|_2}{\lambda_1 |v_1^\top u_t|^{p-2}\sqrt{1-|v_1^\top u_t|^2}} \\
\le & \tan\theta(v_1, u_t) \cdot \frac{\|\widetilde{E}_{u_t}\|_2}{\lambda_1 |v_1^\top u_t|^{p-2}\sqrt{1-|v_1^\top u_t|^2}} && \text{by } \|V^\top \widetilde{E}_{u_t}\|_2 \le \|\widetilde{E}_{u_t}\|_2 \\
\le & \tan\theta(v_1, u_t) \cdot \frac{c_0 pk \|\widetilde{E}_{u_t}\|_2}{\lambda_1 |v_1^\top u_t|^{p-2}} && \text{by } 1/\sqrt{1-|v_1^\top u_t|^2} \le c_0 pk
\end{aligned}$$

We need to bound $\frac{c_0 pk \|\widetilde{E}_{u_t}\|_2}{\lambda_1 |v_1^\top u_t|^{p-2}}$. On one side, we can show

$$\lambda_1 |v_1^\top u_t|^{p-2} \ge \lambda_1 / (n^{(p-2)/2}).$$

On the other side, by Part 1 of Lemma 22.9.12 and assumption on $\overline{E}$ and E, we have $\|\widetilde{E}_{u_t}\|_2$

$$c_0 pk \|\widetilde{E}_{u_t}\|_2 \le c_0 pk \cdot 4p\epsilon.$$

Thus, as long as we choose sufficiently small ϵ such that $\epsilon \le \lambda_1 / (n^{(p-2)/2} \cdot 40 \cdot c_0 p^2 k)$, then $B \le 0.1 \tan\theta(v_1, u_t)$.

If $|v_1^\top u_t| > 1 - \frac{1}{c_0^2 k^2 p^2}$, we have

$$\begin{aligned}
B &= \frac{\|V^\top \widetilde{E}_{u_t}\|_2}{\lambda_1 |v_1^\top u_t|^{p-1}} \\
&\leq \frac{\|V^\top \widetilde{E}_{u_t}\|_2}{\lambda_1 (1 - \frac{1}{c_0^2 p^2 k^2})^{p-1}} && \text{by } |v_1^\top u_t| > 1 - \frac{1}{c_0^2 p^2 k^2} \\
&\leq 3\|V^\top \widetilde{E}_{u_t}\|_2 / \lambda_1 && \text{by } 1/(1 - \frac{1}{c_0^2 p^2 k^2})^{p-1} \leq 3, \forall p \geq 3, k \geq 1, c_0 \geq 1 \\
&\leq 3\|\widetilde{E}_{u_t}\|_2 / \lambda_1
\end{aligned}$$

By Part 1 of Corollary 22.9.13, we have $\|\widehat{E}_{u_t}\|_2 \leq 4\epsilon/c_0$. By assumption on E and $\overline{E}$, we have $\|E_{u_t}\|_2 \leq \epsilon/c_0$ and $\|\overline{E}_{u_t}\|_2 \leq \epsilon/c_0$. Thus, we complete the proof $B \leq 18\epsilon/(c_0\lambda_1)$.

Part 2. For any $j \in [k]\backslash\{1\}$, we have lower bound $\frac{|v_1^\top u_{t+1}|}{|v_j^\top u_{t+1}|}$,

$$\begin{aligned}
&\frac{|v_1^\top u_{t+1}|}{|v_j^\top u_{t+1}|} \\
=\ & \frac{|v_1^\top [A^*(I, u_t, \cdots, u_t) + \widetilde{E}_{u_t}]|}{|v_j^\top [A^*(I, u_t, \cdots, u_t) + \widetilde{E}_{u_t}]|} && \text{by definition of } u_{t+1} \\
\geq\ & \frac{|v_1^\top A^*(I, u_t, \cdots, u_t)| - |v_1^\top \widetilde{E}_{u_t}|}{|v_j^\top A^*(I, u_t, \cdots, u_t)| + |v_j^\top \widetilde{E}_{u_t}|} && \text{by triangle inequality} \\
\geq\ & \frac{\lambda_1 |v_1^\top u_t|^{p-1} - |v_1^\top \widetilde{E}_{u_t}|}{\lambda_j |v_j^\top u_t|^{p-1} + |v_j^\top \widetilde{E}_{u_t}|} && \text{by Fact 22.9.3} \\
\geq\ & \frac{\lambda_1 |v_1^\top u_t|^{p-1} - \frac{1}{10}\lambda_1 |v_1^\top u_t|^{p-1}}{\lambda_j |v_j^\top u_t|^{p-1} + \frac{1}{10}\lambda_1 |v_1^\top u_t|^{p-1}} && \text{by } |v_j^\top \widetilde{E}_{u_t}| \leq \frac{1}{10}\lambda_1 |v_1^\top u_t|^{p-1} \\
\geq\ & \frac{\lambda_1 |v_1^\top u_t|^{p-1} - \frac{1}{10}\lambda_1 |v_1^\top u_t|^{p-1}}{\frac{1}{4}\lambda_1 |v_1^\top u_t|^{p-2} |v_j^\top u_t| + \frac{1}{10}\lambda_1 |v_1^\top u_t|^{p-1}} && \text{by Part 1. } \lambda_j |v_j^\top u_t|^{p-2} \leq \frac{1}{4}\lambda_1 |v_1^\top u_t|^{p-2} \\
=\ & \frac{\frac{9}{10}|v_1^\top u_t|}{\frac{1}{4}|v_j^\top u_t| + \frac{1}{10}|v_1^\top u_t|} && (22.15)
\end{aligned}$$

If $|v_j^\top u_t| < |v_1^\top u_t|$, then

$$\frac{\lambda_1 |v_1^\top u_{t+1}|^{p-2}}{\lambda_j |v_j^\top u_{t+1}|^{p-2}} \geq \frac{\lambda_1}{\lambda_j} 2^{p-2},$$

where the last step follows by $p \geq 4$. Note that for $p = 3$ we apply the better analysis like the proof of Lemma C.2 in [WA16]. Thus, it works for any $p \geq 3$.

If $|v_j^\top u_t| \geq |v_1^\top u_t|$, then

$$\frac{\lambda_1 |v_1^\top u_{t+1}|^{p-2}}{\lambda_j |v_j^\top u_{t+1}|^{p-2}} \geq \frac{\lambda_1}{\lambda_j} \frac{|v_1^\top u_t|^{p-2}}{|v_j^\top u_t|^{p-2}} 2^{p-2} \geq 4 \cdot 2^{p-2}.$$

Part 3. Similarly as Equation (22.15) and Part 1, we can also upper bound $\frac{|v_j^\top u_{t+1}|}{|v_1^\top u_{t+1}|}$,

$$\begin{aligned}
\frac{|v_j^\top u_{t+1}|}{|v_1^\top u_{t+1}|} &\leq \frac{\lambda_j |v_j^\top u_t|^{p-1} + |v_j^\top \widetilde{E}_{u_t}|}{\lambda_1 |v_1^\top u_t|^{p-1} - |v_1^\top \widetilde{E}_{u_t}|} \\
&= \frac{|v_j^\top u_t|}{|v_1^\top u_t|} \cdot \frac{\lambda_j |v_j^\top u_t|^{p-2} + |v_j^\top \widetilde{E}_{u_t}|/|v_j^\top u_t|}{\lambda_1 |v_1^\top u_t|^{p-2} - |v_1^\top \widetilde{E}_{u_t}|/|v_1^\top u_t|} \\
&= \frac{|v_j^\top u_t|}{|v_1^\top u_t|} \cdot \frac{\lambda_j |v_j^\top u_t|^{p-2}}{\lambda_1 |v_1^\top u_t|^{p-2} - |v_1^\top \widetilde{E}_{u_t}|/|v_1^\top u_t|} + \frac{|v_j^\top \epsilon_t|}{\lambda_1 |v_1^\top u_t|^{p-1} - |v_1^\top \widetilde{E}_{u_t}|} \\
&\leq \frac{|v_j^\top u_t|}{|v_1^\top u_t|} \cdot \frac{1}{4} \cdot \underbrace{\frac{1}{1 - |v_1^\top \widetilde{E}_{u_t}|/(\lambda_1 |v_1^\top u_t|^{p-1})}}_{A} + \underbrace{\frac{1}{1 - |v_1^\top \widetilde{E}_{u_t}|/(\lambda_1 |v_1^\top u_t|^{p-1})}}_{A} \cdot \underbrace{\frac{|v_j^\top \widetilde{E}_{u_t}|}{\lambda_1 |v_1^\top u_t|^{p-1}}}_{B}
\end{aligned}$$

Similarly as before, we can show $A \leq 1.1$ and if $|v_1^\top u_t| \geq 1 - \frac{1}{c_0^2 p^2 k^2}$. It remains to bound B. We give a proof by considering two cases separately, one is $|v_1^\top u_t| \leq 1 - \frac{1}{c_0^2 p^2 k^2}$ and the other

is $|v_1^\top u_t| > 1 - \frac{1}{c_0^2 p^2 k^2}$. If $|v_1^\top u_t| \le (1 - \frac{1}{c_0^2 p^2 k^2})$, we have

$$\begin{aligned}
B &= \frac{|v_j^\top \widetilde{E}_{u_t}|}{\lambda_1 |v_1^\top u_t|^{p-1}} \\
&= \frac{\sqrt{1 - |v_1^\top u_t|^2}}{|v_1^\top u_t|} \cdot \frac{|v_j^\top \widetilde{E}_{u_t}|}{\lambda_1 |v_1^\top u_t|^{p-2} \sqrt{1 - |v_1^\top u_t|^2}} \\
&= \tan\theta(v_1, u_t) \cdot \frac{|v_j^\top \widetilde{E}_{u_t}|}{\lambda_1 |v_1^\top u_t|^{p-2} \sqrt{1 - |v_1^\top u_t|^2}} \\
&\le \tan\theta(v_1, u_t) \cdot \frac{c_0 pk |v_j^\top \widetilde{E}_{u_t}|}{\lambda_1 |v_1^\top u_t|^{p-2}} && \text{by } 1/\sqrt{1 - |v_1^\top u_t|^2} \le c_0 pk
\end{aligned}$$

We need to bound $\frac{c_0 pk \|\widetilde{E}_{u_t}\|_2}{\lambda_1 |v_1^\top u_t|^{p-2}}$. On one side, we can show

$$\lambda_1 |v_1^\top u_t|^{p-2} \ge \lambda_1 / (n^{(p-2)/2}).$$

On the other side, by Part 2 of Lemma 22.9.12 and assumption on $\overline{E}$ and E, we have $|v_j^\top \widetilde{E}_{u_t}|$

$$c_0 pk |v_j^\top \widetilde{E}_{u_t}| \le c_0 pk \cdot 4\epsilon / \sqrt{n}.$$

Thus, as long as we choose sufficiently small ϵ such that $\epsilon \le \lambda_1 \sqrt{n} / (n^{(p-2)/2} \cdot 40 \cdot c_0 pk)$, then $B \le 0.1 \tan\theta(v_1, u_t)$.

If $|v_1^\top u_t| > 1 - \frac{1}{c_0^2 k^2 p^2}$, we have

$$\begin{aligned}
B &= \frac{|v_j^\top \widetilde{E}_{u_t}|}{\lambda_1 |v_1^\top u_t|^{p-1}} \\
&\le \frac{|v_j^\top \widetilde{E}_{u_t}|}{\lambda_1 (1 - \frac{1}{c_0^2 p^2 k^2})^{p-1}} && \text{by } |v_1^\top u_t| > 1 - \frac{1}{c_0^2 p^2 k^2} \\
&\le 3 |v_j^\top \widetilde{E}_{u_t}| / \lambda_1 && \text{by } 1/(1 - \frac{1}{c_0^2 p^2 k^2})^{p-1} \le 3, \forall p \ge 3, k \ge 1, c_0 \ge 1 \\
&\le 3 |v_j^\top \widetilde{E}_{u_t}| / \lambda_1
\end{aligned}$$

By Part 1 of Corollary 22.9.13, we have $|v_j^\top \widehat{E}_{u_t}| \le 4\epsilon/(c_0\sqrt{n})$. By assumption on E and $\overline{E}$, we have $|v_j^\top E_{u_t}| \le \epsilon/(c_0\sqrt{n})$ and $|v_j^\top \overline{E}_{u_t}| \le \epsilon/(c_0\sqrt{n})$. Thus, we complete the proof $B \le 18\epsilon/(c_0\lambda_1\sqrt{n})$. □

Definition 22.9.1. For any $\epsilon > 0$, we say $\{\widehat{\lambda}_i, \widehat{v}_i\}_{i=1}^k$ is ϵ-close to $\{\lambda_i, v_i\}_{i=1}^k$ if for all $i \in [k]$,

1. $|\widehat{\lambda}_i - \lambda_i| \le \epsilon$.
2. $\|\widehat{v}_i - v_i\|_2 \le \tan\theta(\widehat{v}_i, v_i) \le \min(\sqrt{2}, \epsilon/(\lambda_i))$.
3. $|\widehat{v}_i^\top v_j| \le \epsilon/(\sqrt{n}\lambda_i)$, $\forall j \in [k]\backslash[i]$.

Lemma 22.9.12. *Let $\widehat{E}_i = \lambda_i v_i^{\otimes p} - \widehat{\lambda}_i \widehat{v}_i^{\otimes p} \in \mathbb{R}^{n^p}, \forall i \in [k]$. For any $\epsilon > 0$, if $\{\widehat{\lambda}_i, \widehat{v}_i\}_{i=1}^k$ is ϵ-close to $\{\lambda_i, v_i\}_{i=1}^k$, then for all $r \in [k]$, for any unit vector $u \in \mathbb{R}^n$,*

1. $\left\|\sum_{i=1}^r \widehat{E}_i(I, u, \cdots, u)\right\|_2 \le 2p\epsilon\kappa^{1/2} + 2\phi\epsilon$.
2. $\forall j \in [k]\backslash[i], \left|\sum_{i=1}^r \widehat{E}_j(v_j, u, \cdots, u)\right| \le (2\kappa\epsilon + \phi\epsilon)/\sqrt{n}$.

where $\kappa = \sum_{i=1}^r |u^\top v_i|^2$ and $\phi = 2k(\epsilon/\lambda_k)^{p-1}$.

Proof. **Part 1.** For each $i \in [r]$, the error $\widehat{E}_i$ is

$$\widehat{E}_i(I, u, \cdots, u) = \lambda_i (u^\top v_i)^{p-1} v_i - \widehat{\lambda}_i (u^\top \widehat{v}_i)^{p-1} \widehat{v}_i$$

lives in $\mathrm{span}\{v_i, \widehat{v}_i\}$; this space is the same as $\mathrm{span}\{v_i, \widehat{v}_i^\perp\}$, where

$$\widehat{v}_i^\perp = \widehat{v}_i - (v_i^\top \widehat{v}_i) v_i$$

is the projection of $\widehat{v}_i$ onto the subspace orthogonal to v_i. Since $\|\widehat{v}_i - v\|_2^2 = 2(1 - v_i^\top \widehat{v}_i)$, it follows that

$$c_i = v_i^\top \widehat{v}_i = 1 - \|\widehat{v}_i - v_i\|_2^2/2 \geq 0$$

(the inequality follows from the assumption $\|\widehat{v}_i - v_i\|_2 \leq \sqrt{2}$, which in turn implies $0 \leq c_i \leq 1$). By the Pythagorean theorem and the above inequality for c_i,

$$\|\widehat{v}_i^\perp\|_2^2 = 1 - c_i^2 \leq \|\widehat{v}_i - v_i\|_2^2.$$

We can obtain this bound, for any $p \geq 3$,

$$|1 - c_i^p| = |1 - (1 - \|\widehat{v}_i - v_i\|_2^2/2)^p| \leq \frac{p}{2}\|\widehat{v}_i - v_i\|_2^2$$

We first define $a_i, b_i \in \mathbb{R}^n$ such that $a_i = u^\top v_i$ and $b_i = u^\top(\widehat{v}_i^\perp/\|\widehat{v}_i^\perp\|_2)$. We now rewrite $\widehat{E}_i(I, u, \cdots, u)$ in terms of the coordinate system defined by v_i and $\widehat{v}_i^\perp$,

$$\begin{aligned}
&\widehat{E}_i(I, u, \cdots, u) \\
=& \lambda_i (u^\top v_i)^{p-1} v_i - \widehat{\lambda}_i (u^\top \widehat{v}_i)^{p-1} \widehat{v}_i \\
=& \lambda_i a_i^{p-1} v_i - \widehat{\lambda}_i (a_i c_i + \|\widehat{v}_i^\perp b_i\|_2)^{p-1} (c_i v_i + \widehat{v}_i^\perp) \\
=& \underbrace{(\lambda_i a_i^{p-1} v_i - \widehat{\lambda}_i (a_i c_i + \|\widehat{v}_i^\perp\|_2 b_i)^{p-1} c_i)}_{A_i} \cdot v_i - \underbrace{\widehat{\lambda}_i (a_i c_i + \|\widehat{v}_i^\perp\|_2 b_i)^{p-1} \|\widehat{v}_i^\perp\|_2}_{B_i} \cdot \widehat{v}_i^\perp / \|\widehat{v}_i^\perp\|_2 \\
=& A_i \cdot v_i - B_i \cdot (\widehat{v}_i^\perp / \|\widehat{v}_i^\perp\|_2)
\end{aligned}$$

The overall error can be written as

$$\begin{aligned}
&\left\|\sum_{i=1}^{r}\widehat{E}_i(I,u,\cdots,u)\right\|_2^2 \\
&= \left\|\sum_{i=1}^{r}A_iv_i-\sum_{i=1}^{t}B_i(\widehat{v}_i^{\perp}/\|\widehat{v}_i^{\perp}\|_2)\right\|_2^2 \\
&\le 2\left\|\sum_{i=1}^{r}A_iv_i\right\|_2^2+2\left\|\sum_{i=1}^{r}B_i(\widehat{v}_i^{\perp}/\|\widehat{v}_i^{\perp}\|_2)\right\|_2^2 \\
&\le 2\sum_{i=1}^{r}A_i^2+2\left(\sum_{i=1}^{r}|B_i|\right)^2
\end{aligned}$$

We first try to bound A_i by using $|\lambda_i-\widehat{\lambda}_i|\le\epsilon$, $\|\widehat{v}_i-v_i\|_2\le\epsilon/\lambda_i$, $\|\widehat{v}_i^{\perp}\|_2^2\le\|\widehat{v}_i-v_i\|_2^2$, $0\le c_i\le 1$ and $|b_i|\le 1$,

$$\begin{aligned}
&|A_i| \\
&= |\lambda_i a_i^{p-1}-\widehat{\lambda}_i(a_ic_i+\|\widehat{v}_i^{\perp}\|_2b_i)^{p-1}c_i| \\
&\le |\lambda_i a_i^{p-1}-\widehat{\lambda}_ic_i^pa_i^{p-1}|+\sum_{j=1}^{p-1}\widehat{\lambda}_ic_i\binom{(p-1)}{j}|a_ic_i|^{(p-1)-j}\|\widehat{v}_i^{\perp}\|_2^j \\
&\le |\lambda_i a_i^{p-1}-\widehat{\lambda}_ia_i^{p-1}|+|(1-c_i^p)\widehat{\lambda}_ia_i^{p-1}|+\sum_{j=1}^{p-1}\widehat{\lambda}_ic_i\binom{(p-1)}{j}|a_ic_i|^{(p-1)-j}(\epsilon/\lambda_i)^j \\
&\le \epsilon|a_i|^{p-1}+\frac{p}{2}(\epsilon/\lambda_i)^2\widehat{\lambda}_i|a_i|^{p-1}+\sum_{j=1}^{p-1}\widehat{\lambda}_i\binom{(p-1)}{j}|a_i|^{(p-1)-j}(\epsilon/\lambda_i)^j
\end{aligned}$$

where the second term can be bounded as

$$\begin{aligned}
\frac{p}{2}(\epsilon/\lambda_i)^2\widehat{\lambda}_i|a_i|^{p-1} &\le \frac{p}{2}(\epsilon/\lambda_i)^2(|\widehat{\lambda}_i-\lambda_i|+|\lambda_i|)|a_i|^{p-1} \\
&\le \frac{p}{2}(\epsilon/\lambda_i)^2\epsilon|a_i|^{p-1}+\frac{p}{2}(\epsilon/\lambda_i)\cdot\epsilon|a_i|^{p-1} \\
&\le \frac{1}{100k}\epsilon|a_i|^{p-1} \qquad \text{by } \epsilon\ll\lambda_i/pk
\end{aligned}$$

The third term can be divided into two parts $j = 1, \cdots, (p-1)/2$ and $j = (p-1)/2, \cdots, (p-1)$. For the first part,

$$\begin{aligned}
&\sum_{j=1}^{(p-1)/2} \widehat{\lambda}_i \binom{(p-1)}{j} |a_i|^{(p-1)-j} (\epsilon/\lambda_i)^j \\
&= \widehat{\lambda}_i (p-1)|a_i|^{p-2}\epsilon/\lambda_i + \sum_{j=2}^{(p-1)/2} \widehat{\lambda}_i (p-1)^j |a_i|^{(p-1)/2} (\epsilon/\lambda_i)^j \\
&\leq (p-1)\epsilon|a_i|^{p-2} + \frac{1}{100k}\epsilon|a_i|^{(p-1)/2}
\end{aligned}$$

Similarly, we can bound the second part,

$$\begin{aligned}
&\sum_{j=(p-1)}^{(p-1)/2} \widehat{\lambda}_i \binom{(p-1)}{j} |a_i|^{(p-1)-j} (\epsilon/\lambda_i)^j \\
&= \widehat{\lambda}_i \cdot 1 \cdot 1 \cdot (\epsilon/\lambda_i)^{p-1} + \sum_{j=(p-1)-1}^{(p-1)/2} \widehat{\lambda}_i \binom{(p-1)}{j} |a_i|^{(p-1)-j} (\epsilon/\lambda_i)^j \\
&\leq \frac{1}{100k}\epsilon + \frac{1}{100k}\epsilon|a_i|
\end{aligned}$$

Thus, putting it all together, we get

$$|A_i| \leq \epsilon|a_i| + \frac{1}{10k}\epsilon|a_i| + (p-1)\epsilon|a_i| + \frac{1}{100k}\epsilon$$

which implies that

$$|A_i|^2 \leq 2\left((\epsilon|a_i|)^2 + (\frac{1}{10k}\epsilon|a_i|)^2 + ((p-1)\epsilon|a_i|)^2 + (\frac{1}{100k}\epsilon)^2\right)$$

It remains to bound B_i,

$$\begin{aligned}
|B_i| &= |\widehat{\lambda}_i \|\widehat{v}_i^{\perp}\|_2 (a_i c_i + \|\widehat{v}_i^{\perp}\|_2 b_i)^{p-1}| \\
&\leq \widehat{\lambda}_i \|\widehat{v}_i^{\perp}\|_2 \sum_{j=0}^{p-1} \binom{(p-1)}{j} |a_i c_i|^{p-1-j} \|\widehat{v}_i^{\perp}\|_2^j \\
&\leq \widehat{\lambda}_i (\epsilon/\lambda_i) \sum_{j=0}^{p-1} \binom{(p-1)}{j} |a_i|^{p-1-j} (\epsilon/\lambda_i)^j \\
&= \widehat{\lambda}_i (\epsilon/\lambda_i) |a_i|^{p-1} + \widehat{\lambda}_i (\epsilon/\lambda_i) \sum_{j=1}^{p-1} \binom{(p-1)}{j} |a_i|^{p-1-j} (\epsilon/\lambda_i)^j
\end{aligned}$$

where the first term can be bounded as

$$\widehat{\lambda}_i (\epsilon/\lambda_i) |a_i|^{p-1} \leq (\epsilon + \lambda_i)(\epsilon/\lambda_i)|a_i|^{p-1} \leq \epsilon |a_i|^{p-1} + \frac{1}{100k}\epsilon |a_i|^{p-1}$$

The second term can be divided into two parts $j = 1, \cdots, (p-1)/2$ and $j = (p-1)/2, \cdots, (p-1)$. For the first part,

$$\begin{aligned}
&(\epsilon/\lambda_i) \sum_{j=1}^{(p-1)/2} \widehat{\lambda}_i \binom{(p-1)}{j} |a_i|^{(p-1)-j} (\epsilon/\lambda_i)^j \\
&= (\epsilon/\lambda_i)\widehat{\lambda}_i (p-1)|a_i|^{p-2}\epsilon/\lambda_i + (\epsilon/\lambda_i) \sum_{j=2}^{(p-1)/2} \widehat{\lambda}_i (p-1)^j |a_i|^{(p-1)/2} (\epsilon/\lambda_i)^j \\
&\leq \frac{1}{100k}\epsilon |a_i|^{p-2} + \frac{1}{100k}\epsilon |a_i|^{(p-1)/2} \qquad \text{by } \epsilon \ll \lambda_i/(kp)
\end{aligned}$$

Similarly, we can bound the second part,

$$\begin{aligned}
&(\epsilon/\lambda_i) \sum_{j=(p-1)}^{(p-1)/2} \widehat{\lambda}_i \binom{(p-1)}{j} |a_i|^{(p-1)-j} (\epsilon/\lambda_i)^j \\
&= (\epsilon/\lambda_i)\widehat{\lambda}_i \cdot 1 \cdot 1 \cdot (\epsilon/\lambda_i)^{p-1} + (\epsilon/\lambda_i) \sum_{j=(p-1)-1}^{(p-1)/2} \widehat{\lambda}_i \binom{(p-1)}{j} |a_i|^{(p-1)-j} (\epsilon/\lambda_i)^j \\
&\leq \frac{\phi}{k}\epsilon + \frac{1}{100k}\epsilon |a_i| \qquad \text{by } \epsilon \ll \lambda_i/kp
\end{aligned}$$

where $\phi = 2k(\epsilon/\lambda_k)^{p-1}$. Putting it all together, we have

$$\begin{aligned}
& |B_i| \leq \epsilon |a_i|^2 + \frac{1}{100k^2}\epsilon |a_i| + \frac{\phi}{k}\epsilon \\
\implies & \sum_{i=1}^{r} |B_i| \leq \epsilon\kappa + \frac{1}{100k^2}\epsilon \sum_{i=1}^{t} |a_i| + \phi\epsilon \\
\implies & (\sum_{i=1}^{r} |B_i|)^2 \leq 2\left((\epsilon\kappa)^2 + (\frac{1}{100k}\epsilon \sum_{i=1}^{t} |a_i|)^2 + (\phi\epsilon)^2 \right) \\
\implies & (\sum_{i=1}^{r} |B_i|)^2 \leq 2\left((\epsilon\kappa)^2 + (\frac{1}{100k}\epsilon)^2 \kappa k + (\phi\epsilon)^2 \right)
\end{aligned}$$

Recall that $\kappa = \sum_{i=1}^{t} |a_i|^2 \leq 1$. Overall, we have

$$\begin{aligned}
& \left\| \sum_{i=1}^{r} \widehat{E}_i(I, u, \cdots, u) \right\|_2^2 \\
&= 2\sum_{i=1}^{r} |A_i|^2 + 2(\sum_{i=1}^{r} |B_i|)^2 \\
&\leq 4\left(\epsilon^2 \cdot \kappa + (\frac{1}{10k}\epsilon)^2 \kappa + (p-1)^2\epsilon^2\kappa + (\frac{1}{100\sqrt{k}}\epsilon)^2 \right) \\
&+ 4\left((\epsilon\kappa)^2 + (\frac{1}{100k}\epsilon)^2 \kappa k + (\phi\epsilon)^2 \right) \\
&\leq 4p^2\epsilon^2\kappa + 4\phi^2\epsilon^2
\end{aligned}$$

which gives the desired bound.

Part 2. For any $j \in [k] \backslash [i]$, we have

$$\begin{aligned}\left|\sum_{i=1}^{r} \widehat{E}_i(v_j, u, \cdots, u)\right| &\leq \sum_{i=1}^{r} |\widehat{E}_i(v_j, u, \cdots, u)| \\ &= \sum_{i=1}^{r} \widehat{\lambda}_i |\widehat{v}_i^\top u|^{p-1} |\widehat{v}_i^\top v_j| \\ &\leq \sum_{i=1}^{t} \widehat{\lambda}_i |\widehat{v}_i^\top u|^{p-1} \frac{\epsilon}{\sqrt{n}\lambda_i},\end{aligned}$$

where the first step follows by triangle inequality, the second step follows by $v_j \cdot v_i, \forall i \neq j$, and the last step follows by part 3 of definition of ϵ-close. Let's try to bound $\sum_{i=1}^{r} \frac{\widehat{\lambda}_i}{\lambda_i} |\widehat{v}_i^\top u|^{p-1}$,

$$\begin{aligned}&\sum_{i=1}^{r} \frac{\widehat{\lambda}_i}{\lambda_i} |\widehat{v}_i^\top u|^{p-1} \\ \leq &\sum_{i=1}^{r} \frac{\widehat{\lambda}_i}{\lambda_i} (|v_i^\top u| + |(v_i - \widehat{v}_i)^\top u|)^{p-1} \\ \leq &\sum_{i=1}^{r} \frac{\widehat{\lambda}_i}{\lambda_i} (|v_i^\top u| + \|v_i - \widehat{v}_i\|_2)^{p-1} \\ \leq &\sum_{i=1}^{r} (1 + \epsilon/\lambda_i)(|v_i^\top u| + \epsilon/\lambda_i)^{p-1} \\ \leq &\, 2\sum_{i=1}^{r} |v_i^\top u|^2 + 2k(\epsilon/\lambda_k)^{p-1} \\ = &\, 2\kappa + \phi.\end{aligned}$$

which gives the desired bound $(2\kappa + \phi)\epsilon/\sqrt{n}$.

□

Corollary 22.9.13. *Let $\widehat{E}_i = \lambda_i v_i^{\otimes p} - \widehat{\lambda}_i \widehat{v}_i^{\otimes p} \in \mathbb{R}^{n^p}, \forall i \in [k]$. For any $c_0 \geq 1$, for any $\epsilon \leq \lambda_k/(2c_0 k)$, if $\{\widehat{\lambda}_i, \widehat{v}_i\}_{i=1}^k$ is ϵ-close to $\{\lambda_i, v_i\}_{i=1}^k$, then for all $r \in [k]$, for any unit vector $u \in \mathbb{R}^n$, $|u^\top v_{r+1}| \geq 1 - \frac{1}{c_0^2 p^2 k}$, then*

1. $\left\|\sum_{i=1}^{r}\widehat{E}_i(I,u,\cdots,u)\right\|_2 \le 2p\epsilon\kappa^{1/2}+2\phi\epsilon \le 4\epsilon/c_0.$

2. $\forall j\in[k]\backslash[i], \left|\sum_{i=1}^{r}\widehat{E}_j(v_j,u,\cdots,u)\right| \le (2\kappa\epsilon+\phi\epsilon)/\sqrt{n} \le 4\epsilon/(c_0\sqrt{n}).$

where $\kappa=\sum_{i=1}^{r}|u^\top v_i|^2$ *and* $\phi=2k(\epsilon/\lambda_k)^{p-1}$.

Proof. Using Fact 22.9.1, we have for any $i\in[r]$,

$$\kappa=\sum_{i=1}^{r}|u^\top v_i|^2 \le k\cdot 1/(c_0^2p^2k) \le 1/c_0^2p^2.$$

which implies $2p\epsilon\sqrt{\kappa}\le 2/c_0$. We also can bound ϕ,

$$\phi=2k(\epsilon/\lambda_k)^{p-1} \le 2k(1/(2c_0k))^2 \le 1/c_0.$$

□

22.9.3 Main result

We first extend the original robust tensor power method analysis to general order $p \geq 3$, i.e., Theorem 22.3.4. Second, we combine Theorem 22.3.4 with our importance sampling techniques, i.e., Corollary 22.7.1 and Lemma 22.8.8.

Theorem 22.3.4. (Main, Abitrary order robust tensor power method) For any $p \geq 3$, $k \geq 1$, for any tensor $A = A^* + E \in \mathbb{R}^{n^p}$, where $A^* = \sum_{i=1}^k \lambda_i v_i^{\otimes p}$ with $\lambda_i > 0$ and orthonormal basis vectors $\{v_1, \ldots, v_k\} \subseteq \mathbb{R}^n$, $n \geq k$. Let λ_1, λ_k be the largest and smallest values in $\{\lambda_i\}_{i=1}^k$ and $\{\widehat{\lambda}_i, \widehat{v}_i\}_{i=1}^k$ be outputs of the robust tensor power method. For any sufficiently large constant $c_0 \geq 100$, there exists a sufficiently small constant $c > 0$, for any $\epsilon \in (0, c\lambda_k/(c_0 p^2 k n^{(p-2)/2})$ if E satisfies that

$$\|E\|_2 \leq \epsilon/(c_0\sqrt{n}) \tag{22.3}$$

and $T = \Omega(\log(\lambda_1 n/\epsilon)), L = \Omega(k\log(k))$, then with probability at least $9/10$, there exists a permutation $\pi : [k] \to [k]$, such that $\forall i \in [k]$,

$$|\lambda_i - \widehat{\lambda}_{\pi(i)}| \leq \epsilon, \quad \|v_i - \widehat{v}_{\pi(i)}\|_2 \leq \epsilon/\lambda_i. \tag{22.4}$$

Proof. We use $E \in \mathbb{R}^{n^p}$ to denote the original noise, use $\widehat{E}_i = \lambda_i v_i^{\otimes p} - \widehat{\lambda}_i \widehat{v}_i^{\otimes p} \in \mathbb{R}^{n^p}$ to denote the deflation noise, use $\overline{E} \in \mathbb{R}^{n^p}$ to denote the sketch noise and use $\widetilde{E}$ to denote the "true" noise that contains both original noise, deflation noise and sketch noise. Thus, in $t+1$ step, we actually observe tensor $A^* + \widetilde{E}$, where $\widetilde{E} = E + \sum_{i=1}^t \widehat{E}_i + \overline{E}$. To prove Theorem 22.3.4, in fact we don't need to worry about sketch noise $\overline{E}$. Instead of assuming it is $\overline{E} = 0$, we prove a strong theorem by assuming sketch noise $\overline{E}$ is bounded, i.e., $\|\overline{E}\|_2 \leq \epsilon/(c_0\sqrt{n})$.

Base case $i = 1$**.** Consider the first step, we get $\widehat{\lambda}_1 \in \mathbb{R}, \widehat{v}_1 \in \mathbb{R}^n$, we first show $\|\widehat{v}_1 - v_1\|_2$ is bounded(as Part 2 of Definition 22.9.1) and then show $|\widehat{\lambda}_1 - \lambda_1|$ is bounded(as Part 1 of Definition 22.9.1). At the end, we show $|\widehat{v}_i^\top v_j|$ is bounded(as Part 3 of Definition 22.9.1).

Bounding $|\widehat{v}_1 - v_1|$**.** So, applying Lemma 22.9.8, we have

$$\tan\theta(u_0, v_1) = \sin\theta(u_0, v_1)/\cos(\theta(u_0, v_1)) \leq \sqrt{n}.$$

Let t^* denote the situation where $|u_{t^*}^\top v_1| = 1 - \frac{1}{c_0^2 p^2 k^2}$. We know

$$\|u_{t^*} - v_1\|_2^2 = 2 - 2|u_{t^*}^\top v_1| = 2/(c_0^2 p^2 k^2).$$

We can upper bound

$$\|u_{t^*} - v_1\|_2 \leq \tan\theta(u_{t^*}, v_1) \leq 0.8 \tan\theta(u_{t^*-1}, v_1) \leq \cdots \leq 0.8^{t^*} \tan\theta(u_0, v_1) \leq 0.8^{t^*}\sqrt{n}$$

Thus, we need to set $t^* = \Omega(\log(nkpc_0)) = \Omega(\log c_0 n)$.

Now, we need to analyze $\|u_T - v_1\|_2$,

$$\|u_T - v_1\|_2 \leq 0.8(\tan\theta(u_T, v_1) + 18\epsilon/(c_0\lambda_1)) \leq \cdots \leq 0.8^{T-t^*} \tan(u_{t^*}, v_1) + 5 \cdot 18\epsilon/(c_0\lambda_1)$$

To guarantee $\|u_T - v_1\|_2 \leq \epsilon/\lambda_1$, we need to choose $T - t^* = \Omega(n\lambda_1/\epsilon)$ and $c_0 \geq 100$. Thus, we get the desired property in Part 2 of Definition 22.9.1.

Bounding $|\widehat{\lambda}_1 - \lambda_1|$. It remains to bound $|\widehat{\lambda}_1 - \lambda_1|$.

$$
\begin{aligned}
|\widehat{\lambda}_1 - \lambda_1| &= |[A^* + \widetilde{E}](\widehat{v}_1, \cdots, \widehat{v}_1) - \lambda_1| \\
&\le |\widetilde{E}(\widehat{v}_1, \cdots, \widehat{v}_1)| + |A^*(\widehat{v}_1, \cdots, \widehat{v}_1) - \lambda_1| && \text{by triangle inequality} \\
&= |\widetilde{E}(\widehat{v}_1, \cdots, \widehat{v}_1)| + \left| \left[\sum_{i=1}^k \lambda_i v_i^{\otimes p} \right] (\widehat{v}_1, \cdots, \widehat{v}_1) - \lambda_1 \right| && \text{by } A^* = \sum_{i=1}^k \lambda_i v_i^{\otimes p} \\
&\le \underbrace{|\widetilde{E}(\widehat{v}_1, \cdots, \widehat{v}_1)|}_{A} + \underbrace{|\lambda_1 |v_1^\top \widehat{v}_1|^p - \lambda_1|}_{B} + \underbrace{\sum_{j=2}^k \lambda_j |v_j^\top \widehat{v}_1|^p}_{C}. && \text{by triangle inequality}
\end{aligned}
$$

For the term A, we have

$$
\begin{aligned}
A &= |\widetilde{E}(\widehat{v}_1, \cdots, \widehat{v}_1)| \\
&\le |E(\widehat{v}_1, \cdots, \widehat{v}_1)\| + |\overline{E}(\widehat{v}_1, \cdots, \widehat{v}_1)| \\
&\le \|E\|_2 + |\overline{E}(\widehat{v}_1, \cdots, \widehat{v}_1)| \\
&\le \epsilon/(c_0\sqrt{n}) + \epsilon/(c_0\sqrt{n}) \\
&\le \epsilon/12 && \text{by } c_0 \ge 100, n \ge 1
\end{aligned}
$$

It remains to upper bound the second term B and the third term C.

$$
\begin{aligned}
B &= \lambda_1 - \lambda_1 (1 - \frac{1}{2}\|v_1 - \widehat{v}_1\|_2^2)^p && \text{by } v_1^\top \widehat{v}_1 = 1 - \frac{1}{2}\|v_1 - \widehat{v}_1\|_2^2 \\
&\le \lambda_1 p \frac{1}{2}\|v_1 - \widehat{v}_1\|_2^2 && \text{by } \|v_1 - \widehat{v}_1\|_2^2 \ll 1 \\
&\le p\epsilon^2/(2\lambda_1) && \text{by } \|v_1 - \widehat{v}_1\|_2 \le \epsilon/\lambda_1 \\
&\le \epsilon/12. && \text{by } p\epsilon/(2\lambda_1) \le 1/12
\end{aligned}
$$

For the term C,

$$
C = \sum_{j=2}^k \lambda_j |v_j^\top \widehat{v}_1|^p \le \sum_{j=2}^k \lambda_j (\epsilon/(\sqrt{n}\lambda_j))^p = \epsilon \sum_{j=2}^k (\epsilon/(\lambda_j\sqrt{n}))^{p-1} \le \epsilon/4.
$$

where the first inequality follows by Part 3 of Definition 22.9.1, and the last step follows by $(\epsilon/\lambda_k)^{p-1} \leq 1/(4k)$. It suffices to set $\epsilon < \frac{1}{4}k^{1/(p-1)}\lambda_k$ Thus, putting it all together, we have

$$|\widehat{\lambda}_1 - \lambda_1| \leq A + B + C \leq \epsilon.$$

Bounding $|\widehat{v}_1^\top v_j|$. We consider any $j \in \{2, \cdots, k\}$. We choose t^* to be smallest integer such that $|v_1^\top u_{t^*}| \geq 1 - \frac{1}{c_0^2 p^2 k^2}$. This implies $|v_j^\top u_{t^*}| \leq \frac{1}{c_0 pk}$. By Part 3 of Lemma 22.9.9, we have

$$|v_j^\top u_{t^*}|/|v_1^\top u_{t^*}| \leq \ 0.8|v_j^\top u_{t^*-1}|/|v_1^\top u_{t^*-1}| \leq \cdots \leq 0.8^{t^*} \cdot u_0 \leq 0.8^{t^*} \cdot 1/(1/\sqrt{n})$$

Thus, we need to choose $t^* = \Omega(\log c_0 n)$.

Let analyze $T > t^*$,

$$|v_j^\top u_T|/|v_1^\top u_T| \leq 0.8^{T-t^*}|v_j^\top u_{t^*}|/|v_1^\top u_{t^*}| + 5 \cdot 18\epsilon/(c_0\lambda_1\sqrt{n}).$$

Thus, we need to choose $T = \Omega(\log(n\lambda_1/\epsilon))$ and $c_0 \geq 100$ to guarantee that $|v_j^\top u_T| \leq \epsilon/(\lambda_1\sqrt{n})$.

The case for $i = r+1$. Conditioned on all the first t cases are holding, let's consider $t+1$ case, then the "true" noise $\widetilde{E} = E + \sum_{i=1}^r E_i + \overline{E} \in \mathbb{R}^{n^p}$. Similarly as the base case $t = 1$, we first show how to bound $\|\widehat{v}_{r+1} - v_{r+1}\|_2$(as Part 2 of Definition 22.9.1), and then we show how to bound $|\widehat{\lambda}_{r+1} - \lambda_{r+1}|$(as Part 1 of Definition 22.9.1), at the end we show how to bound $|v_{r+1}^\top v_j|$(as Part 3 of Definition 22.9.1).

Bounding $\|\widehat{v}_{r+1} - v_{r+1}\|_2$. The proof is identical to the Base case, the difference is, we need to choose $T = \Omega(\log(n\lambda_{t+1}/\epsilon))$.

Bounding $|\widehat{\lambda}_{r+1} - \lambda_{r+1}|$. We redefine A^* and $\widetilde{E}$ to be $A^* = \sum_{i=t+1}^{k} \lambda_i v_i^{\otimes p}$ and $\widetilde{E} = E + \overline{E} + \sum_{i=1}^{t} \widehat{E}_i$. Then rewrite $|\widehat{\lambda}_{t+1} - \lambda_{t+1}|$ as follows

$$
\begin{aligned}
& |\widehat{\lambda}_{r+1} - \lambda_{r+1}| \\
= & |[A^* + \widetilde{E}](\widehat{v}_{r+1}, \cdots, \widehat{v}_{r+1}) - \lambda_{r+1}| \\
\leq & |\widetilde{E}(\widehat{v}_{r+1}, \cdots, \widehat{v}_{r+1})| + |A^*(\widehat{v}_{r+1}, \cdots, \widehat{v}_{r+1}) - \lambda_{r+1}| && \text{by triangle inequality} \\
= & |\widetilde{E}(\widehat{v}_{r+1}, \cdots, \widehat{v}_{r+1})| + \left| \left[\sum_{i=r+1}^{k} \lambda_i v_i^{\otimes p} \right] (\widehat{v}_{r+1}, \cdots, \widehat{v}_{r+1}) - \lambda_{r+1} \right| && \text{by } A^* = \sum_{i=r+1}^{k} \lambda_i v_i^{\otimes p} \\
\leq & \underbrace{|\widetilde{E}(\widehat{v}_{r+1}, \cdots, \widehat{v}_{r+1})|}_{A} + \underbrace{|\lambda_{r+1} |v_{r+1}^\top \widehat{v}_{r+1}|^p - \lambda_{r+1}|}_{B} + \underbrace{\sum_{j=r+2}^{k} \lambda_j |v_j^\top \widehat{v}_{r+1}|^p}_{C}. && \text{by triangle inequality}
\end{aligned}
$$

We need to analyze A,

$$
\begin{aligned}
A = & |\widetilde{E}(\widehat{v}_{r+1}, \cdots, \widehat{v}_{r+1})| \\
= & |E(\widehat{v}_{r+1}, \cdots, \widehat{v}_{r+1})| + |\overline{E}(\widehat{v}_{r+1}, \cdots, \widehat{v}_{r+1})| + |\sum_{i=1}^{r} \widehat{E}_i(\widehat{v}_{r+1}, \cdots, \widehat{v}_{r+1})| \\
\leq & \epsilon/(c_0\sqrt{n}) + \epsilon/(c_0\sqrt{n}) + 4\epsilon/(c_0\sqrt{n}) \\
\leq & \epsilon/12. && \text{by } c_0 \geq 100, n \geq 1
\end{aligned}
$$

Bounding $|\widehat{v}_{r+1}^\top v_j|$. We consider any $j \in \{r+2, \cdots, k\}$. The proof is identical to the base. □

Theorem 22.9.14 (Arbitrary even order sublinear time robust tensor power method)**.** *There exists some sufficiently small constant $\gamma \in (0,1)$ such that any $p \in [3, n^\gamma]$, $k \in [1, n^\gamma]$. There exists some sufficiently small constant $\alpha \in (0, 1 - 20\gamma)$ such that for any tensor $A = A^* + E \in \mathbb{R}^{n^p}$, where $A^* = \sum_{i=1}^{k} \lambda_i v_i^{\otimes p}$ with $\lambda_i > 0$ and orthonormal basis vectors*

$\{v_1, \ldots, v_k\} \subseteq \mathbb{R}^n$. *Let* λ_1, λ_k $(\geq 1/n^\gamma)$ *be the largest and smallest values in* $\{\lambda_i\}_{i=1}^k$ *and* $\{\widehat{\lambda}_i, \widehat{v}_i\}_{i=1}^k$ *be outputs of the "importance sampling" robust tensor power method. For any sufficiently large constant* $c_0 \geq 100$*, there exists a sufficiently small constant* $c > 0$*, for any* $\epsilon \in (0, c\lambda_k/(c_0 p^2 k n^{(p-2)/2})$ *if* E *satisfies that* $\|E\|_2 \leq \epsilon/(c_0\sqrt{n})$ *and if* $T = \Omega(\log(\lambda_1 n/\epsilon)), L = \Omega(k\log(k)), m = \Omega(TLk^2), b = \Omega(mnc_0^2/\epsilon^2)$ *then our algorithm uses* $O(nk)$ *spaces, runs in* $O(n^{p-\alpha})$ *time and then with probability at least* $9/10$*, there exists a permutation* $\pi : [k] \to [k]$*, such that* $\forall i \in [k]$*,*

$$|\lambda_i - \widehat{\lambda}_{\pi(i)}| \leq \epsilon, \qquad \|v_i - \widehat{v}_{\pi(i)}\|_2 \leq \epsilon/\lambda_i.$$

Proof. It follows by combining Theorem 22.3.4, Corollary 22.7.1 and Theorem 22.8.9 . The total number of iterations is $m = \Omega(TLk^2)$, thus we need to take the union bound over all the iterations. The total running time is $O(mb) = n^{p-\alpha'}(\log \lambda_1 n)^2/\lambda_k^2$, where α' is some sufficiently small constant. □

22.11 Additional Experiment Results

The following sections gather all of our experiment results we collected to compare our sampling-based robust tensor power method to a sketching-based robust tensor power method. Our algorithm has the following parameters to set:

1. T: Number of power iterations
2. L: The number of starting vectors of the robust tensor power method
3. B: The number of sketches used in sketching, or the number of repetitions of sampling
4. b: The size of the sketch, or the number of indices sampled

In all of our experiments, we fix $T = 30$, $L = 50$, and change B and b for each input tensor. We observe the squared residual Frobenius norm to evaluate the performance of each algorithm. We only compute the first eigenvalue and eigenvector (rank-1 recovery) of each tensor. This enables us to run a large collection of tensors within a reasonable time.

22.11.1 Synthetic tensors with inverse decaying eigenvalues

The tables shown in this section use synthetic tensors generated with eigenvalues decaying as $\lambda_i = \frac{1}{i}$. All tensors have rank $k = 100$ and added noise with $\sigma = 0.01$.

22.11.3 Synthetic tensors with linearly decaying eigenvalues

The tables shown in this section use synthetic tensors generated with eigenvalues decaying as $\lambda_i = 1 - \frac{i-1}{k}$. All tensors have rank $k = 100$ and added noise $\sigma = 0.01$. Due to the slowly decaying eigenvalues, we expect to see large residual values of rank-1 decomposition, and both algorithms have to work harder to get a better recovery. Our sampling based method works better especially when the dimension is large.

22.11.4 Results from real-life datasets

Dataset	# Documents	# Vocabulary	# Words	Short Description
Wiki	114274	10000	58508288	Wikipedia articles, preprocessed by authors of [WTSA15]
Enron [3]	186501	10000	16971591	Enron Email Dataset, preprocessed by authors of [WTSA15]
AP [4]	2246	10473	435838	Associated Press [BNJ01]
NIPS [5]	1500	12419	1900000	NIPS full papers, preprocessed by UCI
KOS [6]	3430	6906	467714	KOS blog, preprocessed by UCI
NSF [7]	49078	22170	4406190	NSF research award abstracts 1990-2003

Table 22.12: List of six real-life datasets

We used the two same datasets as the previous work [WTSA15]: Wiki and Enron, as well as four additional real-life datasets, shown in Table 22.12. We use the program from the authors of [TWZS15] to build a $K \times K \times K$ tensor A_{LDA} for each dataset. Due to limited time our experiments only use $K = 200$. We expect to gain more over the sketching-based method on larger tensors.

Since these tensors comes from real-world applications and are not normalized, their Frobenius norm is usually very large.

Part V

Open Problems

Chapter 23

Open Problems

In this chapter we give a long list of open problems . Some of these problems have appeared in other places and might be well-known to researchers in the community; nevertheless we include them since they are related to this thesis in some way.

To encourage people to solve these problems, we offer cash for each problem. The reward of each problem is not decided by the importance of the problem, but rather determined by the time when it is solved. To decide the order of time, we will compare the arXiv ID. For the i-th problem solved, we will pay $0.01 \times 2^{i-1}$ dollars.

23.1 Linear Programs

Linear programs are among most important optimization problems from both theoretical and practical view. In a recent result, [CLS19] show how to solve linear programs in the current matrix multiplication time. It would be interesting if this is still true if we are in a world where $n \times n$ matrix multiplication can be done in $O(n^2)$ time.

Open Problem 1. *Is it possible to solve linear programs in the matrix multiplication time?*

Another question is whether we can solve linear programs faster on sparse input. [LS14, LS15] show how to solve linear program in $O(\sqrt{d} \cdot \text{nnz}(A) + d^{2.5})$ time, where $\text{nnz}(A)$ is the number of non-zeros in A and d is the number of constraints.

Open Problem 2. *Is it possible to solve linear programs in the input sparsity time?*

There are other well-known open problems in the theory of linear programming. One important question is whether there is a strongly polynomial time algorithm.

Open Problem 3. *Does LP admit a strongly polynomial time algorithm?*

We concluded open problems on linear programs with a problem originally proposed by Seve Smale [Sma98] in 1998.

Open Problem 4 (Problem 9 in [Sma98])**.** *Is there a polynomial-time algorithm over the real numbers which decides the feasibility of the linear system of inequalities $Ax \geq b$?*

23.2 Matrix Multiplication

Let ω denote the exponent of matrix multiplication. Let α denote the dual exponent of the matrix multiplication.

Open Problem 5. *Is it possible that* $\omega \geq 2.5 - \alpha/2$*?*

For the current value of $\omega \sim 2.38$ and $\alpha \sim 0.31$, this is true. If $\omega = 2$, then $\alpha = 1$, it is also true. For the motivation of this inequality, we refer readers to [CLS19, LSZ19].

We also state a very well-known problem about matrix multiplication

Open Problem 6. *What is the right answer of* ω*?*

23.3 Ordinary Differential Equations

The following open problem is conjectured by Yin Tat Lee.

Open Problem 7. *[LSV18] gives an algorithm for sampling logconcave densities under m-strong convexity and M-smoothness. It takes $\kappa^{1.5}$ iterations (where $\kappa := M/m$), $O(1)$ gradient evaluation per iteration, and the total time is $\kappa^{1.5}d$. Is that possible to give an algorithm that takes κ iterations, and $O(1)$ gradient evaluation per iteration?*

23.4 Matrix Factorization

We discuss several open problems about matrix/tensor factorization in this section.

23.4.1 Weighted Factorization

Recall the definition of weighted low rank approximation

Definition 23.4.1. Given a matrix $A \in \mathbb{R}^{n\times n}$ and a matrix $W \in \mathbb{R}^{n\times n}$. Let W denote a rank-r weight matrix. For integer $k \geq 1$ and approximation ratio $\alpha > 1$, the goal is to find a rank-k matrix $B \in \mathbb{R}^{n\times n}$ such that

$$\|W \circ (B - A)\|_F \leq \alpha \cdot \min_{\text{rank}-k\ A'} \|W \circ (A' - A)\|_F.$$

We assume the entries of A and W are integers in the range $\{-M, -M+1, \cdots, M\}$ for an integer $M \leq 2^{\text{poly}(n)}$, i.e., that the entries of A and W can be specified with $\text{poly}(n)$ bits.

Open Problem 8. *For $k = O(1)$ and $\alpha = O(1)$, [RSW16] showed an $n^{O(r)}$ upper bound and a $2^{\Omega(r)}$ lower bound under Feige-*ETH*. Is it possible to close the gap?*

The above question was originally asked by David P. Woodruff (see Open Problem 9 in [CFHW17]).

Open Problem 9. *If W has r distinct columns (which is a stronger assumption than W has* rank-r*), [RSW16] showed $2^{\widetilde{O}(r^2)}$ upper bound and $2^{\Omega(r)}$ lower bound under Feige-*ETH*, is it possible to close the gap?*

23.4.2 Nonnegative Matrix Factorization

Nonnegative matrix factorization was theoretically studied by [AGKM12] and [Moi13]. The formal definition is

Definition 23.4.2 (NMF)**.** Given an $n \times n$ matrix A and a parameter k, the goal is to output two nonnegative $n \times k$ matrices U and $V^\top$ such that $UV = A$.

Open Problem 10. *There is an algorithm for NMF that takes $n^{O(k^2)}$ time due to [Moi13]. Under* ETH*, any algorithm that solves NMF takes $n^{\Omega(k)}$ time. The question is, can we close the gap?*

23.4.3 Tensor factorization

Tensor factorization/decomposition has many applications in computer science. We give a formal problem definition.

Definition 23.4.3. Given a $n \times n \times n$ tensor A and a parameter k, the goal is to output three $n \times k$ matrices U, V, W such that

$$\|U \otimes V \otimes W - A\|_F \leq O(1) \min_{\mathrm{rank}-k\ A_k} \|A_k - A\|_F.$$

Open Problem 11. *[SWZ19b] propose an algorithm that takes $\mathrm{nnz}(A) + n \cdot \mathrm{poly}(k) + 2^{O(k^2)}$ time. From the other perspective, [SWZ19b] show that there is no algorithm that takes $2^{o(k)}$ time unless Feige-*ETH *is false. For the situation $k = \omega(\log n)$, can we close the gap between $2^{O(k^2)}$ and $2^{\Omega(k)}$?*

In fact, all three open problems are equivalent in some sense. If someone can solve one of them, then probably also can improve the remaining ones. From the lower bound

side, all the current hardness results are based on ETH-type assumption. We don't know how to boost the current reduction. From the algorithmic side, all the current results are based on polynomial system solver, which has exponential dependence on the number of variables. For the target rank-k matrices, we don't know how to write down a system that only involves $o(k^2)$ variables.

23.5 Continuous Fourier Transform

23.5.1 One dimensional

We say $x(t) : \mathbb{R} \to \mathbb{C}$ is a k-Fourier-sparse signal if $x(t)$ can be written as $x(t) = \sum_{j=1}^{k} v_j e^{-2\pi \mathbf{i} f_j t}$ where $v_j \in \mathbb{C}$ and $f_j \in \mathbb{R}$, $\forall j \in [k]$. Let $\|x\|_T = (\frac{1}{T}\int_0^T |x(t)|^2 \mathrm{d}t)^{1/2}$.

Open Problem 12. *[CKPS16] showed that : for any k-Fourier-sparse signal $x(t) : \mathbb{R} \to \mathbb{C}$ and any duration $T > 0$, we have*

$$\max_{t \in [0,T]} |x(t)|^2 \leq O(k^4 \log^3 k) \cdot \|x\|_T^2.$$

[CKPS16] also showed that $\Omega(k^2)$ is necessary. Can we close the gap?

23.5.2 High dimensional

We say $x(t) : \mathbb{R}^d \to \mathbb{C}$ is a d-dimensional k-Fourier-sparse signal if $x(t)$ can be written as $x(t) = \sum_{j=1}^{k} v_j e^{-2\pi \mathbf{i} f_j^\top t}$ where $v_j \in \mathbb{C}$ and $f_j \in \mathbb{R}^d$, $\forall j \in [k]$. Let $\|x\|_T = (\frac{1}{T^d}\int_{[0,T]^d} |x(t)|^2 \mathrm{d}t)^{1/2}$.

Open Problem 13. *[Son17] showed that : for any d-dimensional k-Fourier-sparse signal $x(t) : \mathbb{R}^d \to \mathbb{C}$ and any duration $T > 0$, we have*

$$\max_{t \in [0,T]^d} |x(t)|^2 \leq k^{O(d)} \cdot \|x\|_T^2.$$

Is it possible to improve the upper bound $k^{O(d)}$, e.g. to $\mathrm{poly}(k, d)$? Is it possible to prove a lower bound of $k^{\Omega(d)}$?

We provide the details of [Son17] in the Chapter 31.

Currently, [PS15] and [CKPS16] are working for $d = 1$ case.

Open Problem 14. *Can we generalize [PS15] and [CKPS16] to arbitrary dimension d?*

23.6 Discrete Fourier Transform

23.6.1 High dimensional

We introduce some notations for high dimensional Fourier transform. We assume that the universe size $n = p^d$ for any positive integer p. Let $\omega = e^{2\pi \mathbf{i}/p}$ where $\mathbf{i} = \sqrt{-1}$. We define the normalized d-dimensional Fourier transform

$$\widehat{x}_f = \frac{1}{\sqrt{n}} \sum_{t \in [p]^d} x_t \cdot \omega^{f^\top t}, \forall f \in [p]^d$$

and the inverse Fourier transform is

$$x_t = \frac{1}{\sqrt{n}} \sum_{f \in [p]^d} \widehat{x}_f \cdot \omega^{-f^\top t}, \forall t \in [p]^d.$$

One important goal for high dimensional Fourier transform is to achieve dimension-free results. We suggest some problems for any $d \geq 1$.

Open Problem 15. *For the noiseless setting, [KVZ19] give an algorithm that uses*

$$O(k^3 \log^2 \log^2 n)$$

samples and $O(k^3 \log^2 k \log^2 n)$ time. This is already dimension-free! If the running time has to be $\mathrm{poly}(k \log n)$, what is the best sample complexity we can achieve?

Open Problem 16. *For the noisy setting, [NSW19a] give an algorithm that uses*

$$O(k \log k \log n)$$

samples and $\widetilde{O}(n)$ running time. Is $O(k \log k \log n)$ the right answer for sample complexity?

Open Problem 17. *For the noisy setting, can we get $\mathrm{poly}(k \log n)$ samples and $\mathrm{poly}(k \log n)$ running times?*

For $d = O(1)$, the state-of-the-art result [Kap16] takes $k \log n \cdot \log \log n$ samples and $k \operatorname{poly}(\log n)$ running times.

Open Problem 18. *For the noisy setting, for $d = O(1)$, what is the right answer for sample complexity?*

23.7 Discrete time continuous frequency Fourier transform

There is a long line of work doing Fourier transform in the discrete setting [GMS05, Iwe08, Iwe10, HIKP12a, HIKP12b, Iwe13, IKP14, IK14, Kap16, Kap17, CI17, NSW18, LN19, NSW19a]. We provide the formal definition here. For ease of discussion, we call it discrete-discrete setting.

Definition 23.7.1 (discrete time discrete frequency Fourier transform, [HIKP12a])**.** Given a vector $\widehat{x} \in \mathbb{C}^n$, an integer k and an approximation ratio $\alpha > 1$. design an algorithm that takes samples from $x \in \mathbb{C}^n$, and outputs a $O(k)$-sparse vector $y \in \mathbb{C}^n$ such that

$$\|y - \widehat{x}\|_2 \leq \alpha \cdot \min_{k-\text{sparse } z} \|z - \widehat{x}\|_2.$$

In general, we hope the number of samples and running time are both $k \operatorname{poly}(\log n)$.

To the best of our knowledge, [PS15] is the first work that defines the robust sparse Fourier transform in the continuous setting. For ease of discussion, we call it continuous-continuous setting.

Definition 23.7.2 (continuous time continuous frequency Fourier transform, [PS15])**.** Let x be a function $x(t) = x^*(t) + g(t)$ where $x^*(t) = \sum_{j=1}^k v_j e^{2\pi \mathbf{i} f_j t}$ (i.e. $x^*(t)$ is a k-Fourier-sparse signal) and $f_j \in [-F, F]$. Let $T > 0$. The goal is to design an algorithm that allows to take samples from $x(t)$ and outputs a $O(k)$-Fourier-sparse signal $y(t)$ such that

$$\frac{1}{T} \int_0^T |y(t) - x(t)|^2 \mathrm{d}t \leq \alpha \cdot \frac{1}{T} \int_0^T |g(t)|^2 \mathrm{d}t.$$

In general, we hope the number of samples and running time are $k \operatorname{poly}(\log FT)$.

For a function $x(t)$, we define

$$\|x(t)\|_T = \left(\frac{1}{T}\int_0^T |x(t)|^2 \mathrm{d}t\right)^{1/2}$$

The following definition is suggested by Jerry Li.

Definition 23.7.3 (discrete time continuous frequency Fourier transform)**.** Given k tones $(v_j, f_j) \in \mathbb{C} \times [0,1]$, we can access $x(t) = \sum_{j=1}^k v_j e^{-2\pi \mathbf{i} f_j t} + g(t)$, $\forall t \in [n]$. The goal is to output a $\mathrm{poly}(k \log n)$-sparse function $y(t)$ such that

$$\sum_{t=1}^n (y(t) - x(t))^2 \leq O(1) \cdot \sum_{t=1}^n g(t)^2.$$

Some interesting questions are:

Open Problem 19. *Can we generalize the continuous Fourier transform techniques in [PS15] to the setting where we are only allowed to take restricted samples (i.e., from integers), if we may assume a frequency gap? Are we still able to recover the continuous frequencies up to some precision, and then reconstruct the signal?*

Open Problem 20. *Can we generalize the continuous Fourier transform techniques in [CKPS16] to the setting where we are only allowed to take restricted samples and reconstruct the signal with finding the true continuous frequencies?*

The discrete time continuous frequency Fourier transform problem naturally arises in the study of learning low-rank Toeplitz covariance matrices. This is a well-studied problem in signal processing, for instance, in relationship to *direction-of-arrival* estimation. Here, we are given samples $X_1, \ldots, X_n$ drawn from a d-dimensional Gaussian with mean 0 and

covariance Σ, which we assume to be Toeplitz, and the goal is to approximately recover Σ. Moreover, we are allowed to access individual coordinates of each X_i one-by-one, and only pay a cost of 1 in the sample complexity for every coordinate we access.

Classical algorithms (such as ruler-based methods, or matrix pencil-based methods), either require a number of samples which is polynomial in the ambient dimension, or are not very tolerant to noise. In [ELMM19], it was demonstrated that by solving the discrete time continuous frequency Fourier transform problem, one can obtain an algorithm which is both robust to noise, and which requires a number of samples which depends only polylogarithmically in the ambient dimension, when Σ is low rank. The aforementioned paper gives an algorithm for this problem which is sample-efficient, but has exponential running time. By instead using hashing-based techniques, one could hope to obtain a polynomial-time algorithm for this problem, which would in turn yield the first efficient algorithm for learning low-rank Toeplitz covariance matrices using only $\operatorname{poly}\log(d)$ samples.

23.8 Applications of Fourier transform

23.8.1 Speeding up linear programs

It is known that Subsampled Randomized Hadamard Transform gives the subspace embedding.

Theorem 23.8.1 ([AC06, Sar06, Tro11b, DMM06a, DMMS11, DMIMW12, LDFU13]). *Let $S = \frac{\sqrt{n}}{\sqrt{r}} P H_n D$, where D is an $n \times n$ diagonal matrix with i.i.d. diagonal entries $D_{i,i}$ in which $D_{i,i} = 1$ with probability $1/2$, and $D_{i,i} = -1$ with probability $1/2$. H_n refers to the Hadamard matrix of size n, which we assume is a power of 2. Here the (i,j)-th entry of H_n is given by $(-1)^{\langle i,j \rangle}/\sqrt{n}$ where $\langle i,j \rangle = \sum_{z=1}^{\log n} i_z \cdot j_z$ and $(i_{\log n}, \cdots, i_1)$ and $(j_{\log n}, \cdots, j_1)$ are the binary representations of i and j respectively. Then $r \times n$ matrix P samples r coordinates of an n-dimensional vector uniformly at random, where*

$$r = \Omega(\epsilon^{-2} \log d \cdot (\sqrt{d} + \sqrt{\log n})^2)$$

Then with probability at least .99, for any fixed $n \times d$ matrix U with orthonormal columns,

$$\| I_d - U^\top S^\top S U \|_2 \leq \epsilon.$$

Further, for any vector $x \in \mathbb{R}^n$, Sx can be computed in $O(n \log r)$ time.

An interesting question is

Open Problem 21. *If we don't use diagonal matrix D, can we show subspace embedding guarantee presented in Theorem 23.8.1, or the guarantee presented in Lemma 3.9.1?*

If the above conjecture holds, then we have more power to design fast algorithm for several fundamental problems, i.e. linear programs.

23.8.2 Proving convergence result for deep neural network

Open Problem 22. *Is the frequency gap assumption in continuous Fourier transform ([PS15]) somehow equivalent to data-separable assumption in deep learning theory ([AZLS18, AZLS19, SY19])?*

The above problem seems strange in some sense, since Fourier transform and deep learning are completely different problems. The motivation of the stating that problem is : 1) Fourier transform seems to be related to kernel regression with random Fourier feature, 2) a recent work shows that an infinite width one-hidden-layer neural network is somehow equivalent to Kernel regression [ADH+19].

23.9 An Over-parameterization Theory of Neural Networks

Over-parameterization theory for deep neural networks becomes extremely popular over the last few years. There is a long line (still growing very quickly) of work proving that (stochastic) gradient descent algorithm is able to find the global minimum if the network is wide enough [LL18, DZPS19, AZLS18, AZLS19, DLL+19, ZCZG18, SY19].

Formally speaking, the existing results show that as long as the width m is at least polynomial of number of input data n, then (S)GD-type algorithm can work in the following sense: first randomly pick a weight matrix to be the initialization point, update the weight matrix according to gradient direction over each iteration, and eventually find the global minimum.

Yin Tat Lee [Lee18] conjectured the following

Open Problem 23. *If m is nearly in n (ignore the polylog factors), then we can prove convergence result for one-hidden layer neural network.*

Next, we want to ask the open questions for multiple layer neural networks. Let L denote the number of layers of the neural network, let n denote the number of input data points, let d denote the dimension of input data points, let δ denote the failure probability, and let m denote the width of the neural network.

Open Problem 24. *For a deep neural network with ReLU activation function, what is the smallest m that suffices to show convergence?*

Similarly, we are also curious about the right answer for RNNs,

Open Problem 25. *For a recurrent neural network with ReLU activation function, what is the smallest m that suffices to show convergence?*

[AZLS18] proved a large polynomial dependence on all the parameters, we believe it is improvable. However, we are not sure about the right answer. Note that all the above three open problems are about training error.

23.10 Matrix Chernoff and Discrepancy

23.10.1 Matrix Chernoff

Open Problem 26. *[KS18] show that $O(\epsilon^{-2}\log^2 n)$ spanning trees suffice to produce a $(1\pm\epsilon)$-spectral graph sparsifier, and that $\Omega(\epsilon^{-2}\log n)$ spanning trees are necessary. Which one is tight? Can we prove matching upper and lower bound?*

For more background on this problem, we refer the reader to [BSST13, KS18].

We consulted some experts[1]. They are not aware of any form of the following Chernoff-type result for hyperbolic polynomials. They believed the following result is interesting.

Open Problem 27. *Given vectors $x_1,\cdots,x_n\in\mathbb{R}^d$ and a polynomial h with respect to e, let us define the hyperbolic norm $\|x\|_h=\max_{i\in[n]}|\lambda_i(x)|$ where $h(te-x)=h(e)\cdot\prod_{i=1}^n(t-\lambda_i(x))$, and suppose $\|x_i\|_h\le 1$ for all $i\in[n]$. If we sample i.i.d. $\epsilon_1,\cdots,\epsilon_n$ uniformly from $\{-1,1\}$, then does*

$$\left\|\sum_{i=1}^n\epsilon_i x_i\right\|_h\le O(\sqrt{n\log n})$$

hold with constant probability?

23.10.2 Discrepancy

Open Problem 28 (Matrix Spencer)**.** *For any symmetric matrices $A_1,\cdots,A_n\in\mathbb{R}^{n\times n}$ with $\|A_i\|\le 1$, do there exist signs $\epsilon_1,\cdots,\epsilon_n\in\{-1,1\}$ such that*

$$\left\|\sum_{i=1}^n\epsilon_i A_i\right\|=O(\sqrt{n}).$$

[1] Personal communication with James Renegar

The above problem is called the Matrix Spencer conjecture, see e.g. [Mek04] and [RR19].

[MSS15b] resolved the Kadison-Singer conjecture, a long-standing open problem, but their proof is non-constructive. From the algorithmic perspective, a major open question is the following:

Open Problem 29. *Given positive semidefinite matrices* $A_1, \cdots, A_m \in \mathbb{R}^{n \times n}$ *and* $\epsilon > 0$ *with* $\sum_{i=1}^m A_i = I_n$ *and* $\mathrm{tr}[A_i] \leq \epsilon$ *for all* $i \in [m]$*, is there a polynomial time algorithm to find signs* $x_1, \ldots, x_m \in \{-1, 1\}$ *such that* $\left\| \sum_{i=1}^m x_i A_i \right\| \leq O(\sqrt{\epsilon})$*?*

In order to describe the next open problems, we provide some definitions:

Definition 23.10.1 ([Brä18])**.** Given a degree d polynomial h that is hyperbolic with respect to $e \in \mathbb{R}^n$, The open hyperbolicity cone of h with respect to e is the set

$$\Gamma_{++}(h, e) = \{x \in \mathbb{R}^n : \lambda_i(x) > 0 \ \forall i \in [n]\}.$$

We also define the closed hyperbolicity cone

$$\Gamma_{+}(h, e) = \{x \in \mathbb{R}^n : \lambda_i(x) \geq 0 \ \forall i \in [n]\},$$

where $h(te - x) = h(e) \cdot \prod_{i=1}^n (t - \lambda_i(x))$.

The trace, rank and spectral radius (with respect to e) of $x \in \mathbb{R}^n$ are defined as for matrices

$$\mathrm{tr}[x] = \sum_{i=1}^n \lambda_i(x), \quad \mathrm{rank}_h(x) = |\{i \in [n] : \lambda_i(x) \neq 0\}|, \quad \text{and} \quad \|x\|_h = \max_{i \in [n]} \lambda_i(x).$$

Recently, [Brä18] generalized Kadison-Singer to hyperbolic polynomials and also higher rank. Note that [MSS15b] can be viewed as the special case when h is the determinant polynomial with rank-1 matrices. [KLS19] generalized [MSS15b] from a different perspective. It would be interesting to combine [KLS19] and [Brä18] to show the following result.

Open Problem 30. *Let h be a polynomial that is hyperbolic with respect to $e \in \mathbb{R}^n$. Let $v_1, \cdots, v_m \in \Gamma_+(h,e)$ with $\mathrm{rank}_h(v_i) \leq 1$, and*

$$\sigma^2 = \left\| \sum_{i=1}^m \mathrm{tr}[v_i] v_i \right\|_h .$$

Then there exists a choice of signs $\epsilon_i \in \{-1, 1\}$ and some constant $c > 0$ such that

$$\left\| \sum_{i=1}^m \epsilon_i v_i \right\|_h \leq c \cdot \sigma.$$

We also wonder if similar techniques can be used to sparsify hyperbolicity cones:

Open Problem 31. *Given $\epsilon > 0$, a polynomial h that is hyperbolic with respect to $e \in \mathbb{R}^n$ and $v_1, \cdots, v_m \in \Gamma_+(h,e)$ with $v_1 + \cdots + v_m = e$, is it always possible to find coefficients $s \in \mathbb{R}^m_{\geq 0}$ such that $|\mathrm{supp}(s)| \leq n/\epsilon^2$ and $\|e - \sum_{i=1}^m s_i v_i\|_h = O(\epsilon)$?*

The above problem can be viewed as a generalization of [BSS12].

23.11 Edit Distance and Longest Common Subsequence

In this section we consider two of the most ubiquitous measures of similarity between a pair of strings: the longest common subsequence (LCS) and the edit distance. The LCS of two n-character strings A and B is simply their longest (not necessarily contiguous) common substring. Edit distance is the minimum number of character insertions, deletions, and substitutions required to transform A and B. In fact, under a slightly more restricted definition that does not allow substitutions, the two measures are complements to each other and the problems of computing them are exactly equivalent.

Under plausible fine-grained complexity assumptions such as SETH, neither edit distance nor LCS can be computed much faster [AWW14, ABW15, BI15, BK15, AHWW16].

For edit distance, an $\widetilde{O}(n + \Delta^2)$-time algorithm of [LMS98] (where Δ is the true edit distance between the strings) implies a linear-time $\sqrt{n}$-approximation algorithm. The approximation factor has been significantly improved in a series of works to $O(n^{3/7})$ [BYJKK04], to $O(n^{0.34})$ [BES06], to $O(2^{\widetilde{O}(\sqrt{\log n})})$ [AO09], and finally to polylogarithmic [AKO10]. A recent work of Boroujeni, Ehsani, Ghodsi, HajiAghayi and Seddighin [BEG+18] obtains a constant factor approximation quantum algorithm for edit distance that runs in truly subquadratic time.

We state three open problems related to edit distance. Two of the problems were originally posted by Aviad Rubinstein [Rub18].

Open Problem 32. *Is there a constant-factor approximation to edit distance that runs in near-linear time?*

Currently, the best approximation ratio is $(3 + \epsilon)$ [RSSS19].

Open Problem 33. *Is there a $(1+\epsilon)$-approximation algorithm for edit distance in truly subquadratic (or near-linear) time?*

Note that there is a more concrete plan to make progress on approximation ratio of edit distance problem. For more details, we refer the readers to [RSSS19].

Note that the current subquadratic time constant approximation edit distance algorithm [CDG+18] is a randomized algorithm. It would be interesting to derandomize the algorithm.

Open Problem 34. *Is there a deterministic subquadratic time constant approximation edit distance algorithm?*

Now let us come to the LCS problem. The textbook dynamic programming algorithm for computing LCS (or edit distance) runs in $O(n^2)$ time, and a slightly faster $O(n^2/\log^2(n))$-time algorithm is known due to Masek and Paterson [MP80]. There is a trivial algorithm that gives 2-approximation for binary strings. Finding faster algorithms is a central and long standing open problem both in theory and in practice (e.g. Problem 35 of [Knu72]).

Rubinstein and Song [RS19b] proposed a truly subquadratic time $(2-\epsilon)$-approximation algorithm for binary strings. Let $|\Sigma|$ be the alphabetical size. Then one natural question is if we can generalize the algorithm for $|\Sigma| = 3, 4$ or some constants.

Open Problem 35. *For any constant $|\Sigma|$, is there a truly subquadratic time algorithm that gives $(|\Sigma| - \epsilon)$-approximation for some constants $\epsilon > 0$?*

Another interesting question is about de-randomization.

Open Problem 36. *Can we de-randomize the* LCS *algorithm in [RSSS19]?*

23.12 Map-Reduce

Many modern parallel systems, such as MapReduce, Hadoop, and Spark, can be modeled well by the MPC model. The MPC model captures well coarse-grained computation on large data - data is distributed to processors, each of which has a sublinear (in the input data) amount of memory and we alternate between rounds of computation and rounds of communication, where each machine can communicate an amount of data as large as the size of its memory.

We consider one fundamental graph problem: connectivity. On an undirected graph with n and m edges, $O(\log n)$ round connectivity algorithm has been known for over 35 years. In 2018, [ASS+18] proposed a new algorithm that only needs $O(\log D \cdot \log\log_{m/n} n)$ where D is the diameter of the graph. Very recently, Behnezhad, Dhulipala, Esfandiari, Lacki and Mirrokni [BDE+19] improved the number of rounds to $O(\log D + \log\log_{m/n} n)$. An interesting open question is

Open Problem 37. *Is there an $O(\log D)$ rounds algorithm for graph connectivity?*

The above problem was originally suggested by Peilin Zhong. In next a few paragraphs, we discuss several other open problems which are proposed by Xiaorui Sun.

Roughgarden, Vassilvitskii and Wang [RVW18] showed that if there is an $\omega(1)$-round MPC lower bound for graph connectivity, then $\mathsf{NC}_1 \neq \mathsf{P}$. Since NC_1 vs P is a well-known hard problem, it is unlikely to prove an $\omega(1)$-round unconditional lower bound for connectivity. Hence, we ask if an conditional lower bound is possible.

Open Problem 38. *Is there an $\omega(1)$-round conditional lower bound for graph connectivity?*

Furthermore, people actually conjectured that any algorithm solve graph connectivity problem requires $\Omega(\log n)$ rounds. This conjecture has been use to show other graph problems are unlikely to have constant round algorithms (Yaroslavtsev and Vadapalli [YV18], Ghaffari, Kuhn and Uitto [GKU19]).

Open Problem 39. *Is there an $\Omega(\log n)$-round conditional lower bound for graph connectivity?*

In a more broader setting, it will be interesting to understand the complexity of MPC. In particular, if all the polynomial-time solvable problem have an efficient MPC algorithm. Since linear programming is P-Complete, we ask

Open Problem 40. *Is there an $O(n^{o(1)})$ rounds algorithm for linear programming?*

Dynamic programming in MPC has been studied recently. Im, Moseley and Sun [IMS17a] and Hajiaghayi, Seddighin and Sun [HSS19] showed that many classic dynamic programming problems have constant rounds approximation algorithms. These problems include weighted interval scheduling, longest increasing subsequence, edit distance and longest common subsequence. But it is unclear if these problems can be solved exactly in constant rounds.

Open Problem 41. *Can dynamic programming problems be solved exactly in $O(1)$ rounds?*

Part VI

More Algorithms for Fundamental Problems

Chapter 24

ℓ_∞ Regression

Sketching has emerged as a powerful technique for speeding up problems in numerical linear algebra, such as regression. In the overconstrained regression problem, one is given an $n \times d$ matrix A, with $n \gg d$, as well as an $n \times 1$ vector b, and one wants to find a vector $\widehat{x}$ so as to minimize the residual error $\|Ax - b\|_2$. Using the sketch and solve paradigm, one first computes $S \cdot A$ and $S \cdot b$ for a randomly chosen matrix S, then outputs $x' = (SA)^\dagger Sb$ so as to minimize $\|SAx' - Sb\|_2$.

The sketch-and-solve paradigm gives a bound on $\|x' - x^*\|_2$ when A is well-conditioned. Our main result is that, when S is the subsampled randomized Fourier/Hadamard transform, the error $x' - x^*$ behaves as if it lies in a "random" direction within this bound: for any fixed direction $a \in \mathbb{R}^d$, we have with $1 - d^{-c}$ probability that

$$\langle a, x' - x^* \rangle \lesssim \frac{\|a\|_2 \|x' - x^*\|_2}{d^{\frac{1}{2}-\gamma}}, \tag{24.1}$$

where $c, \gamma > 0$ are arbitrary constants. This implies $\|x' - x^*\|_\infty$ is a factor $d^{\frac{1}{2}-\gamma}$ smaller than $\|x' - x^*\|_2$. It also gives a better bound on the generalization of x' to new examples: if rows of A correspond to examples and columns to features, then our result gives a better bound for the error introduced by sketch-and-solve when classifying fresh examples. We show that not all oblivious subspace embeddings S satisfy these properties. In particular, we give

counterexamples showing that matrices based on Count-Sketch or leverage score sampling do not satisfy these properties.

We also provide lower bounds, both on how small $\|x' - x^*\|_2$ can be, and for our new guarantee (24.1), showing that the subsampled randomized Fourier/Hadamard transform is nearly optimal. Our lower bound on $\|x' - x^*\|_2$ shows that there is an $O(1/\epsilon)$ separation in the dimension of the optimal oblivious subspace embedding required for outputting an x' for which $\|x' - x^*\|_2 \leq \epsilon \|Ax^* - b\|_2 \cdot \|A^\dagger\|_2$, compared to the dimension of the optimal oblivious subspace embedding required for outputting an x' for which $\|Ax' - b\|_2 \leq (1+\epsilon)\|Ax^* - b\|_2$, that is, the former problem requires dimension $\Omega(d/\epsilon^2)$ while the latter problem can be solved with dimension $O(d/\epsilon)$. This explains the reason known upper bounds on the dimensions of these two variants of regression have differed in prior work.

This part is based upon the following previous publication

  Fast Regression with an ℓ_∞ Guarantee.
  ICALP 2017 [PSW17]

24.1 Introduction

Oblivious subspace embeddings (OSEs) were introduced by Sarlos [Sar06] to solve linear algebra problems more quickly than traditional methods. An OSE is a distribution of matrices $S \in \mathbb{R}^{m \times n}$ with $m \ll n$ such that, for any d-dimensional subspace $U \subset \mathbb{R}^n$, with "high" probability S preserves the norm of every vector in the subspace. OSEs are a generalization of the classic Johnson-Lindenstrauss lemma from vectors to subspaces. Formally,

we require that with probability $1 - \delta$,

$$\|Sx\|_2 = (1 \pm \epsilon) \|x\|_2$$

simultaneously for all $x \in U$, that is, $(1 - \epsilon) \|x\|_2 \leq \|Sx\|_2 \leq (1 + \epsilon) \|x\|_2$.

A major application of OSEs is to regression. The regression problem is, given $b \in \mathbb{R}^n$ and $A \in \mathbb{R}^{n \times d}$ for $n \geq d$, to solve for

$$x^* = \operatorname*{argmin}_{x \in \mathbb{R}^d} \|Ax - b\|_2 \tag{24.2}$$

Because A is a "tall" matrix with more rows than columns, the system is overdetermined and there is likely no solution to $Ax = b$, but regression will find the closest point to b in the space spanned by A. The classic answer to regression is to use the Moore-Penrose pseudoinverse: $x^* = A^\dagger b$ where

$$A^\dagger = (A^\top A)^{-1} A^\top$$

is the "pseudoinverse" of A (assuming A has full column rank, which we will typically do for simplicity). This classic solution takes $O(nd^{\omega-1} + d^\omega)$ time, where $\omega < 2.373$ is the matrix multiplication constant [CW90, Wil12, LG14]: $nd^{\omega-1}$ time to compute $A^\top A$ and d^ω time to compute the inverse.

OSEs speed up the process by replacing (24.2) with

$$x' = \operatorname*{argmin}_{x \in \mathbb{R}^d} \|SAx - Sb\|_2$$

for an OSE S on $d + 1$-dimensional spaces. This replaces the $n \times d$ regression problem with an $m \times d$ problem, which can be solved more quickly since $m \ll n$. Because $Ax - b$ lies in

the $d+1$-dimensional space spanned by b and the columns of A, with high probability S preserves the norm of $SAx - Sb$ to $1 \pm \epsilon$ for all x. Thus,

$$\|Ax' - b\|_2 \leq \frac{1+\epsilon}{1-\epsilon} \|Ax^* - b\|_2 .$$

That is, S produces a solution x' which preserves the *cost* of the regression problem. The running time for this method depends on (1) the reduced dimension m and (2) the time it takes to multiply S by A. We can compute these for "standard" OSE types:

- If S has i.i.d. Gaussian entries, then $m = O(d/\epsilon^2)$ is sufficient (and in fact, $m \geq d/\epsilon^2$ is required [NN14]). However, computing SA takes $O(mnd) = O(nd^2/\epsilon^2)$ time, which is worse than solving the original regression problem (one can speed this up using fast matrix multiplication, though it is still worse than solving the original problem).

- If S is a subsampled randomized Hadamard transform (SRHT) matrix with random sign flips (see Theorem 2.4 in [Woo14a] for a survey, and also see [AC06, Sar06, DMM06c, DMMS11, KW11, Tro11b, DMIMW12, LDFU13, AL13, Bou14, HR16, CNW16]), then m increases to $\widetilde{O}(d/\epsilon^2 \cdot \log n)$, where $\widetilde{O}(f) = f \operatorname{poly}(\log(f))$. But now, we can compute SA using the fast Hadamard transform in $O(nd \log n)$ time. This makes the overall regression problem take $O(nd \log n + d^\omega/\epsilon^2)$ time.

- If S is a random sparse matrix with random signs (the "Count-Sketch" matrix), then $m = d^{1+\gamma}/\epsilon^2$ suffices for $\gamma > 0$ a decreasing function of the sparsity [CW13, MM13, NN13a, BDN15, Coh16a]. (The definition of a Count-Sketch matrix is, for any $s \geq 1$, $S_{i,j} \in \{0, -1/\sqrt{s}, 1/\sqrt{s}\}$, $\forall i \in [m], j \in [n]$ and the column sparsity of matrix S is s. Independently in each column s positions are chosen uniformly at random without

replacement, and each chosen position is set to $-1/\sqrt{s}$ with probability 1/2, and $+1/\sqrt{s}$ with probability 1/2.) Sparse OSEs can benefit from the sparsity of A, allowing for a running time of $\widetilde{O}(\text{nnz}(A)) + \widetilde{O}(d^\omega/\epsilon^2)$, where $\text{nnz}(A)$ denotes the number of non-zeros in A.

When n is large, the latter two algorithms are substantially faster than the naïve $nd^{\omega-1}$ method.

24.1.1 Our Contributions

Despite the success of using subspace embeddings to speed up regression, often what practitioners are interested is not in preserving the cost of the regression problem, but rather in the *generalization* or *prediction* error provided by the vector x'. Ideally, we would like for any future (unseen) example $a \in \mathbb{R}^d$, that $\langle a, x' \rangle \approx \langle a, x^* \rangle$ with high probability.

Ultimately one may want to use x' to do classification, such as regularized least squares classification (RLSC) [RYP03], which has been found in cases to do as well as support vector machines but is much simpler [ZP04]. In this application, given a training set of examples with multiple (non-binary) labels identified with the rows of an $n \times d$ matrix A, one creates an $n \times r$ matrix B, each column indicating the presence or absence of one of the r possible labels in each example. One then solves the multiple response regression problem $\min_X \|AX - B\|_F$, and uses X to classify future examples. A commonly used method is for a future example a, to compute $\langle a, x_1 \rangle, \ldots, \langle a, x_r \rangle$, where $x_1, \ldots, x_r$ are the columns of X. One then chooses the label i for which $\langle a, x_i \rangle$ is maximum.

For this to work, we would like the inner products $\langle a, x'_1 \rangle, \ldots, \langle a, x'_r \rangle$ to be close to

$\langle a, x_1^* \rangle, \ldots, \langle a, x_r^* \rangle$, where X' is the solution to $\min_X \|SAX - SB\|_F$ and X^* is the solution to $\min_X \|AX - B\|_F$. For any $O(1)$-accurate OSE on $d+r$ dimensional spaces [Sar06], which also satisfies so-called approximate matrix multiplication with error $\epsilon' = \epsilon/\sqrt{(d+r)}$, we get that

$$\|x' - x^*\|_2 \leq O(\epsilon) \cdot \|Ax^* - b\|_2 \cdot \left\|A^\dagger\right\|_2 \tag{24.3}$$

where $\left\|A^\dagger\right\|$ is the spectral norm of $A^\dagger$, which equals the reciprocal of the smallest singular value of A. To obtain a generalization error bound for an unseen example a, one has

$$|\langle a, x^* \rangle - \langle a, x' \rangle| = |\langle a, x^* - x' \rangle| \leq \|x^* - x'\|_2 \|a\|_2 = O(\epsilon)\|a\|_2 \|Ax^* - b\|_2 \left\|A^\dagger\right\|_2, \tag{24.4}$$

which could be tight if given only the guarantee in (24.3). However, if the difference vector $x' - x^*$ were distributed in a uniformly random direction subject to (24.3), then one would expect an $\widetilde{O}(\sqrt{d})$ factor improvement in the bound. This is what our main theorem shows:

Theorem 24.1.1 (Main Theorem, informal)**.** *Suppose $n \leq \text{poly}(d)$ and matrix $A \in \mathbb{R}^{n \times d}$ and vector $b \in \mathbb{R}^n$ are given. Let $S \in \mathbb{R}^{m \times n}$ be a subsampled randomized Hadamard transform matrix with $m = d^{1+\gamma}/\epsilon^2$ rows for an arbitrarily small constant $\gamma > 0$. For $x' = \text{argmin}_{x \in \mathbb{R}^d} \|SAx - Sb\|_2$ and $x^* = \text{argmin}_{x \in \mathbb{R}^d} \|Ax - b\|_2$, and any fixed $a \in \mathbb{R}^d$,*

$$|\langle a, x^* \rangle - \langle a, x' \rangle| \leq \frac{\epsilon}{\sqrt{d}} \|a\|_2 \|Ax^* - b\|_2 \left\|A^\dagger\right\|_2. \tag{24.5}$$

with probability $1 - 1/d^C$ for an arbitrarily large constant $C > 0$. This implies that

$$\|x^* - x'\|_\infty \leq \frac{\epsilon}{\sqrt{d}} \|Ax^* - b\|_2 \left\|A^\dagger\right\|_2. \tag{24.6}$$

with $1 - 1/d^{C-1}$ probability.

If $n > \text{poly}(d)$, then by first composing S with a Count-Sketch OSE with $\text{poly}(d)$ rows, one can achieve the same guarantee.

(Here γ is a constant going to zero as n increases; see Theorem 24.3.3 for a formal statement of Theorem 24.1.1.)

Notice that Theorem 24.1.1 is considerably stronger than that of (24.4) provided by existing guarantees. Indeed, in order to achieve the guarantee (24.6) in Theorem 24.1.1, one would need to set $\epsilon' = \epsilon/\sqrt{d}$ in existing OSEs, resulting in $\Omega(d^2/\epsilon^2)$ rows. In contrast, we achieve only $d^{1+\gamma}/\epsilon^2$ rows. We can improve the bound in Theorem 24.1.1 to $m = d/\epsilon^2$ if S is a matrix of i.i.d. Gaussians; however, as noted, computing $S \cdot A$ is slower in this case.

Note that Theorem 24.1.1 also *makes no distributional assumptions* on the data, and thus the data could be heavy-tailed or even adversarially corrupted. This implies that our bound is still useful when the rows of A are not sampled independently from a distribution with bounded variance.

The ℓ_∞ bound (24.6) of Theorem 24.1.1 is achieved by applying (24.5) to the standard basis vectors $a = e_i$ for each $i \in [d]$ and applying a union bound. This ℓ_∞ guarantee often has a more natural interpretation than the ℓ_2 guarantee—if we think of the regression as attributing the observable as a sum of various factors, (24.6) says that the contribution of each factor is estimated well. One may also see our contribution as giving a way for estimating the pseudoinverse $A^\dagger$ *entrywise*. Namely, we get that $(SA)^\dagger S \approx A^\dagger$ in the sense that each entry is within additive $O(\epsilon\sqrt{\frac{\log d}{d}}\left\|A^\dagger\right\|_2)$. There is a lot of work on computing entries of inverses of a matrix, see, e.g., [ADL+12, LAKD08].

Another benefit of the ℓ_∞ guarantee is when the regression vector x^* is expected to be k-*sparse* (e.g. [Lee12]). In such cases, thresholding to the top k entries will yield an ℓ_2 guarantee a factor $\sqrt{\frac{k}{d}}$ better than (24.3).

One could ask if Theorem 24.1.1 also holds for sparse OSEs, such as the Count-Sketch. Surprisingly, we show that one cannot achieve the generalization error guarantee in Theorem 24.1.1 with high probability, say, $1 - 1/d$, using such embeddings, despite the fact that such embeddings do approximate the cost of the regression problem up to a $1 + \epsilon$ factor with high probability. This shows that the generalization error guarantee is achieved by some subspace embeddings but not all.

Theorem 24.1.2 (Not all subspace embeddings give the ℓ_∞ guarantee; informal version of Theorem 24.8.1)**.** *The Count-Sketch matrix with $d^{1.5}$ rows and sparsity $d^{.25}$—which is an OSE with exponentially small failure probability—with constant probability will have a result x' that does not satisfy the ℓ_∞ guarantee (24.6).*

We can show that Theorem 24.1.1 holds for S based on the Count-Sketch OSE T with $d^{O(C)}/\epsilon^2$ rows with $1 - 1/d^C$ probability. We can thus compose the Count-Sketch OSE with the SRHT matrix and obtain an $O(\text{nnz}(A)) + \text{poly}(d/\epsilon)$ time algorithm to compute $S \cdot TA$ achieving (24.6). We can also compute $R \cdot S \cdot T \cdot A$, where R is a matrix of Gaussians, which is more efficient now that STA only has $d^{1+\gamma}/\epsilon^2$ rows; this will reduce the number of rows to d/ϵ^2.

Another common method of dimensionality reduction for linear regression is *leverage score sampling* [DMIMW12, LMP13, PKB14, CMM15], which subsamples the rows of A by choosing each row with probability proportional to its "leverage scores". With $O(d \log(d/\delta)/\epsilon^2)$ rows taken, the result x' will satisfy the ℓ_2 bound (24.3) with probability $1 - \delta$. However, it does not give a good ℓ_∞ bound:

Theorem 24.1.3 (Leverage score sampling does not give the ℓ_∞ guarantee; informal version

of Theorem 24.9.1). *Leverage score sampling with $d^{1.5}$ rows—which satisfies the ℓ_2 bound with exponentially small failure probability—with constant probability will have a result x' that does not satisfy the ℓ_∞ guarantee (24.6).*

Finally, we show that the $d^{1+\gamma}/\epsilon^2$ rows that SRHT matrices use is roughly optimal:

Theorem 24.1.4 (Lower bounds for ℓ_2 and ℓ_∞ guarantees; informal versions of of Theorem 24.5.1 and Corollary 24.5.3)**.** *Any sketching matrix distribution over $m \times n$ matrices that satisfies either the ℓ_2 guarantee (24.3) or the ℓ_∞ guarantee (24.6) must have $m \gtrsim \min(n, d/\epsilon^2)$.*

Notice that our result shows the necessity of the $1/\epsilon$ separation between the results originally defined in Equation (3) and (4) of Theorem 12 of [Sar06]. If we want to output some vector x' such that $\|Ax' - b\|_2 \leq (1+\epsilon)\|Ax^* - b\|_2$, then it is known that $m = \Theta(d/\epsilon)$ is necessary and sufficient. However, if we want to output a vector x' such that $\|x' - x^*\|_2 \leq \epsilon\|Ax^* - b\|_2 \cdot \|A^\dagger\|_2$, then we show that $m = \Theta(d/\epsilon^2)$ is necessary and sufficient.

Comparison to Gradient Descent While this work is primarily about sketching methods, one could instead apply iterative methods such as gradient descent, after appropriately preconditioning the matrix, see, e.g., [AMT10, ZF13, CW13]. That is, one can use an OSE with constant ϵ to construct a preconditioner for A and then run conjugate gradient using the preconditioner. This gives an overall dependence of $\log(1/\epsilon)$.

The main drawback of this approach is that one loses the ability to save on storage space or number of passes when A appears in a stream, or to save on communication or rounds when A is distributed. Given increasingly large data sets, such scenarios are now quite common, see, e.g., [CW90] for regression algorithms in the data stream model. In

situations where the entries of A appear sequentially, for example, a row at a time, one does not need to store the full $n \times d$ matrix A but only the $m \times d$ matrix SA.

Also, iterative methods can be less efficient when solving multiple response regression, where one wants to minimize $\|AX - B\|$ for a $d \times t$ matrix X and an $n \times t$ matrix B. This is the case when ϵ is constant and t is large, which can occur in some applications (though there are also other applications for which ϵ is very small). For example, conjugate gradient with a preconditioner will take $\widetilde{O}(ndt)$ time while using an OSE directly will take only $\widetilde{O}(nd + d^2t)$ time (since one effectively replaces n with $O(d)$ after computing $S \cdot A$), separating t from d. Multiple response regression, arises, for example, in the RLSC application above.

Proof Techniques **Theorem 24.1.1.** As noted in Theorem 24.1.2, there are some OSEs for which our generalization error bound does not hold. This hints that our analysis is non-standard and cannot use generic properties of OSEs as a black box. Indeed, in our analysis, we have to consider matrix products of the form $S^\top S(UU^\top S^\top S)^k$ for our random sketching matrix S and a fixed matrix U, where k is a positive integer. We stress that it is the *same matrix* S appearing multiple times in this expression, which considerably complicates the analysis, and does not allow us to appeal to standard results on approximate matrix product (see, e.g., [Woo14a] for a survey). The key idea is to recursively reduce $S^\top S(UU^\top S^\top S)^k$ using a property of S. We use properties that only hold for specifics OSEs S: first, that each column of S is unit vector; and second, that for all pairs (i, j) and $i \neq j$, the inner product between S_i and S_j is at most $\frac{\sqrt{\log n}}{\sqrt{m}}$ with probability $1 - 1/\operatorname{poly}(n)$.

Theorems 24.8.1 and 24.9.1. To show that Count-Sketch does not give the ℓ_∞ guar-

antee, we construct a matrix A and vector b as in Figure 24.1, which has optimal solution x^* with all coordinates $1/\sqrt{d}$. We then show, for our setting of parameters, that there likely exists an index $j \in [d]$ satisfying the following property: the jth column of S has disjoint support from the kth column of S for all $k \in [d+\alpha] \setminus \{j\}$ except for a single $k > d$, for which S_j and S_k share exactly one common entry in their support. In such cases we can compute x'_j explicitly, getting $|x'_j - x^*_j| = \frac{1}{s\sqrt{\alpha}}$. By choosing suitable parameters in our construction, this gives that $\|x' - x^*\|_\infty \gg \frac{1}{\sqrt{d}}$. The lower bound for leverage score sampling follows a similar construction.

Theorem 24.5.1 and Corollary 24.5.3. The lower bound proof for the ℓ_2 guarantee uses Yao's minimax principle. We are allowed to fix an $m \times n$ sketching matrix S and design a distribution over $[A\ b]$. We first write the sketching matrix $S = U\Sigma V^\top$ in its singular value decomposition (SVD). We choose the $d+1$ columns of the adjoined matrix $[A, b]$ to be random orthonormal vectors. Consider an $n \times n$ orthonormal matrix R which contains the columns of V as its first m columns, and is completed on its remaining $n - m$ columns to an arbitrary orthonormal basis. Then $S \cdot [A, b] = V^\top RR^\top \cdot [A, b] = [U\Sigma I_m, 0] \cdot [R^\top A, R^\top b]$. Notice that $[R^\top A, R^\top b]$ is equal in distribution to $[A, b]$, since R is fixed and $[A, b]$ is a random matrix with $d+1$ orthonormal columns. Therefore, $S \cdot [A, b]$ is equal in distribution to $[U\Sigma G, U\Sigma h]$ where $[G, h]$ corresponds to the first m rows of an $n \times (d+1)$ uniformly random matrix with orthonormal columns.

A key idea is that if $n = \Omega(\max(m, d)^2)$, then by a result of Jiang [Jia06], any $m \times (d+1)$ submatrix of a random $n \times n$ orthonormal matrix has $o(1)$ total variation distance to a $d \times d$ matrix of i.i.d. $N(0, 1/n)$ random variables, and so any events that

would have occurred had G and h been independent i.i.d. Gaussians, occur with the same probability for our distribution up to an $1 - o(1)$ factor, so we can assume G and h are independent i.i.d. Gaussians in the analysis.

The optimal solution x' in the sketch space equals $(SA)^\dagger Sb$, and by using that SA has the form $U\Sigma G$, one can manipulate $\|(SA)^\dagger Sb\|$ to be of the form $\|\widetilde{\Sigma}^\dagger(\Sigma R)^\dagger \Sigma h\|_2$, where the SVD of G is $R\widetilde{\Sigma}T$. We can upper bound $\|\widetilde{\Sigma}\|_2$ by $\sqrt{r/n}$, since it is just the maximum singular value of a Gaussian matrix, where r is the rank of S, which allows us to lower bound $\|\widetilde{\Sigma}^\dagger(\Sigma R)^\dagger \Sigma h\|_2$ by $\sqrt{n/r}\|(\Sigma R)^\dagger \Sigma h\|_2$. Then, since h is i.i.d. Gaussian, this quantity concentrates to $\frac{1}{\sqrt{r}}\|(\Sigma R)^\dagger \Sigma h\|$, since $\|Ch\|^2 \approx \|C\|_F^2/n$ for a vector h of i.i.d. $N(0, 1/n)$ random variables. Finally, we can lower bound $\|(\Sigma R)^\dagger \Sigma\|_F^2$ by $\|(\Sigma R)^\dagger \Sigma R R^\top\|_F^2$ by the Pythagorean theorem, and now we have that $(\Sigma R)^\dagger \Sigma R$ is the identity, and so this expression is just equal to the rank of ΣR, which we prove is at least d. Noting that $x^* = 0$ for our instance, putting these bounds together gives $\|x' - x^*\| \geq \sqrt{d/r}$. The last ingredient is a way to ensure that the rank of S is at least d. Here we choose another distribution on inputs A and b for which it is trivial to show the rank of S is at least d with large probability. We require S be good on the mixture. Since S is fixed and good on the mixture, it is good for both distributions individually, which implies we can assume S has rank d in our analysis of the first distribution above.

24.1.2 Notation

For a positive integer, let $[n] = \{1, 2, \ldots, n\}$. For a vector $x \in \mathbb{R}^n$, define $\|x\|_2 = (\sum_{i=1}^n x_i^2)^{\frac{1}{2}}$ and $\|x\|_\infty = \max_{i \in [n]} |x_i|$. For a matrix $A \in \mathbb{R}^{m \times n}$, define $\|A\|_2 = \sup_x \|Ax\|_2/\|x\|_2$ to be the spectral norm of A and $\|A\|_F = (\sum_{i,j} A_{i,j}^2)^{1/2}$ to be the Frobenius norm of A. We

use $A^\dagger$ to denote the Moore-Penrose pseudoinverse of $m \times n$ matrix A, which if $A = U\Sigma V^\top$ is its SVD (where $U \in \mathbb{R}^{m\times n}$, $\Sigma \in \mathbb{R}^{n\times n}$ and $V \in \mathbb{R}^{n\times}$ for $m \geq n$), is given by $A^\dagger = V\Sigma^{-1}U^\top$.

In addition to $O(\cdot)$ notation, for two functions f, g, we use the shorthand $f \lesssim g$ (resp. $\gtrsim$) to indicate that $f \leq Cg$ (resp. $\geq$) for an absolute constant C. We use $f \eqsim g$ to mean $cf \leq g \leq Cf$ for constants c, C.

Definition 24.1.1 (Subspace Embedding)**.** A $(1 \pm \epsilon)$ ℓ_2-subspace embedding for the column space of an $n \times d$ matrix A is a matrix S for which for all $x \in \mathbb{R}^d$, $\|SAx\|_2^2 = (1 \pm \epsilon)\|Ax\|_2^2$.

Definition 24.1.2 (Approximate Matrix Product)**.** Let $0 < \epsilon < 1$ be a given approximation parameter. Given matrices A and B, where A and B each have n rows, the goal is to output a matrix C so that $\|A^\top B - C\|_F \leq \epsilon\|A\|_F\|B\|_F$. Typically C has the form $A^\top S^\top SB$, for a random matrix S with a small number of rows. In particular, this guarantee holds for the subsampled randomized Hadamard transform S with $O(\epsilon^{-2})$ rows [DMMS11].

24.2 Warmup: Gaussians OSEs

We first show that if S is a Gaussian random matrix, then it satisfies the generalization guarantee. This follows from the rotational invariance of the Gaussian distribution.

Theorem 24.2.1. *Suppose $A \in \mathbb{R}^{n\times d}$ has full column rank. If the entries of $S \in \mathbb{R}^{m\times n}$ are i.i.d. $N(0, 1/m)$, $m = O(d/\epsilon^2)$, then for any vectors a, b and $x^* = A^\dagger b$, we have, with probability $1 - 1/\operatorname{poly}(d)$,*

$$|a^\top (SA)^\dagger Sb - a^\top x^*| \lesssim \frac{\epsilon\sqrt{\log d}}{\sqrt{d}} \|a\|_2 \|b - Ax^*\|_2 \left\|A^\dagger\right\|_2.$$

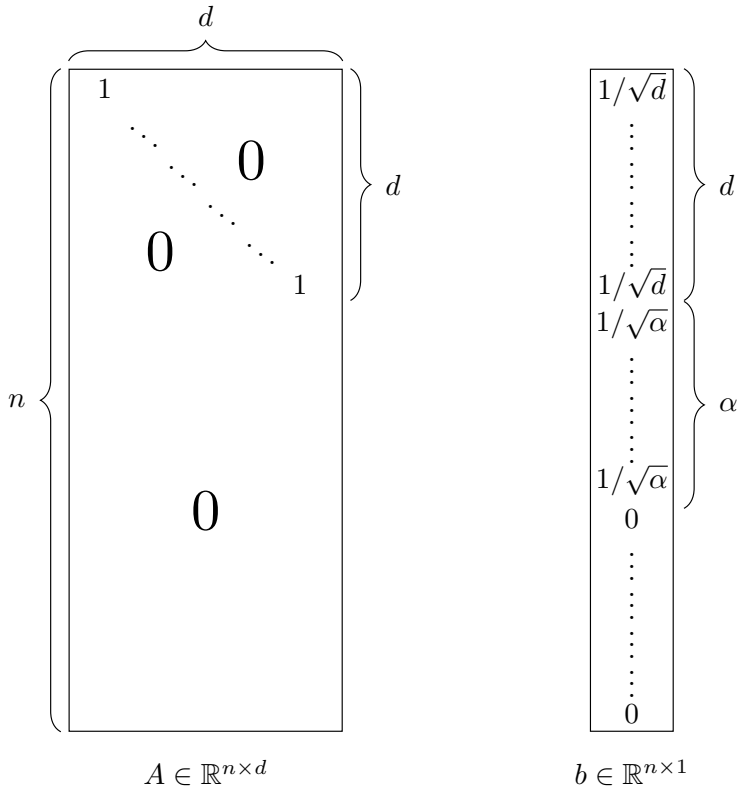

Figure 24.1: Our construction of A and b for the proof that Count-Sketch does not obey the ℓ_∞ guarantee. $\alpha < d$.

Because SA has full column rank with probability 1, $(SA)^\dagger SA = I$. Therefore

$$|a^\top (SA)^\dagger Sb - a^\top x^*| = |a^\top (SA)^\dagger S(b - Ax^*)| = |a^\top (SA)^\dagger S(b - AA^\dagger b)|.$$

Thus it suffices to only consider vectors b where $A^\dagger b = 0$, or equivalently $U^\top b = 0$. In such cases, SU will be independent of Sb, which will give the result. The proof is in Appendix 24.6.

24.3 SRHT Matrices

We first provide the definition of the subsampled randomized Hadamard transform (SRHT): let $S = \frac{1}{\sqrt{rn}} P H_n D$. Here, D is an $n \times n$ diagonal matrix with i.i.d. diagonal entries $D_{i,i}$, for which $D_{i,i}$ in uniform on $\{-1, +1\}$. The matrix H_n is the Hadamard matrix of size $n \times n$, and we assume n is a power of 2. Here, $H_n = [H_{n/2},\ H_{n/2}; H_{n/2},\ -H_{n/2}]$ and $H_1 = [1]$. The $r \times n$ matrix P samples r coordinates of an n dimensional vector uniformly at random.

For other subspace embeddings, we no longer have that SU and Sb are independent. To analyze them, we start with a claim that allows us to relate the inverse of a matrix to a power series.

Claim 24.3.1. *Let $S \in \mathbb{R}^{m \times n}$, $A \in \mathbb{R}^{n \times d}$ have SVD $A = U\Sigma V^\top$, and define $T \in \mathbb{R}^{d \times d}$ by*

$$T = I_d - U^\top S^\top S U.$$

Suppose SA has linearly independent columns and $\|T\|_2 \leq 1/2$. Then

$$(SA)^\dagger S = V\Sigma^{-1} \left(\sum_{k=0}^{\infty} T^k \right) U^\top S^\top S. \tag{24.7}$$

Proof.

$$\begin{aligned}
(SA)^\dagger S &= (A^\top S^\top S A)^{-1} A^\top S^\top S \\
&= (V\Sigma U^\top S^\top S U \Sigma V^\top)^{-1} V \Sigma U^\top S^\top S \\
&= V\Sigma^{-1} (U^\top S^\top S U)^{-1} U^\top S^\top S \\
&= V\Sigma^{-1} (I_d - T)^{-1} U^\top S^\top S \\
&= V\Sigma^{-1} \left(\sum_{k=0}^{\infty} T^k \right) U^\top S^\top S,
\end{aligned}$$

where in the last equality, since $\|T\|_2 < 1$, the von Neumann series $\sum_{k=0}^{\infty} T^k$ converges to $(I_d - T)^{-1}$. □

We then bound the kth term of this sum:

Lemma 24.3.2. Let $S \in \mathbb{R}^{r \times n}$ be the subsampled randomized Hadamard transform, and let a be a unit vector. Then with probability $1 - 1/\mathrm{poly}(n)$, we have

$$\begin{aligned}&|a^\top S^\top S(UU^\top S^\top S)^k b| \\ &= O(\log^k n) \cdot (O(d(\log n)/r) + 1)^{\frac{k-1}{2}} \cdot (\sqrt{d}\|b\|_2(\log n)/r + \|b\|_2(\log^{\frac{1}{2}} n)/r^{\frac{1}{2}})\end{aligned}$$

Hence, for r at least $d \log^{2k+2} n \log^2(n/\epsilon)/\epsilon^2$, this is at most $O(\|b\|_2 \epsilon/\sqrt{d})$ with probability at least $1 - 1/\mathrm{poly}(n)$.

We defer the proof of this lemma to the next section, and now show how the lemma lets us prove that SRHT matrices satisfy the generalization bound with high probability:

Theorem 24.3.3. *Suppose $A \in \mathbb{R}^{n \times d}$ has full column rank with $\log n = d^{o(1)}$. Let $S \in \mathbb{R}^{m \times n}$ be a subsampled randomized Hadamard transform with $m = O(d^{1+\alpha}/\epsilon^2)$ for $\alpha = \Theta(\sqrt{\frac{\log\log n}{\log d}})$. For any vectors a, b and $x^* = A^\dagger b$, we have*

$$|a^\top (SA)^\dagger Sb - a^\top x^*| \lesssim \frac{\epsilon}{\sqrt{d}} \|a\|_2 \|b - Ax^*\|_2 \left\|\Sigma^{-1}\right\|_2$$

with probability $1 - 1/\mathrm{poly}(d)$.

Proof. Define $\Delta = \Theta\left(\frac{1}{\sqrt{m}}\right) (\log^c d) \|a\|_2 \|b - Ax^*\|_2 \|\Sigma^{-1}\|_2$. For a constant $c > 0$, we have that S is a $(1 \pm \gamma)$-subspace embedding (Definition 24.1.1) for $\gamma = \sqrt{\frac{d \log^c n}{m}}$ with probability $1 - 1/\mathrm{poly}(d)$ (see, e.g., Theorem 2.4 of [Woo14a] and references therein), so $\|SUx\|_2 =$

$(1 \pm \gamma) \|Ux\|_2$ for all x, which we condition on. Hence for $T = I_d - U^\top S^\top S U$, we have $\|T\|_2 \le (1+\gamma)^2 - 1 \lesssim \gamma$. In particular, $\|T\|_2 < 1/2$ and we can apply Claim 24.3.1.

As in Section 24.2, SA has full column rank if S is a subspace embedding, so $(SA)^\dagger SA = I$ and we may assume $x^* = 0$ without loss of generality.

By the approximate matrix product (Definition 24.1.2), we have for some c that

$$|a^\top V \Sigma^{-1} U^\top S^\top S b| \le \frac{\log^c d}{\sqrt{m}} \|a\|_2 \|b\|_2 \left\|\Sigma^{-1}\right\|_2 \le \Delta \tag{24.8}$$

with $1 - 1/\mathrm{poly}(d)$ probability. Suppose this event occurs, bounding the $k = 0$ term of (24.7). Hence it suffices to show that the $k \ge 1$ terms of (24.7) are bounded by Δ.

By approximate matrix product (Definition 24.1.2), we also have with $1 - 1/d^2$ probability that

$$\left\|U^\top S^\top S b\right\|_F \le \frac{\log^c d}{\sqrt{m}} \left\|U^\top\right\|_F \|b\|_2 \le \frac{\log^c d \sqrt{d}}{\sqrt{m}} \|b\|_2 .$$

Combining with $\|T\|_2 \lesssim \gamma$ we have for any k that

$$|a^\top V \Sigma^{-1} T^k U^\top S^\top S b| \lesssim \gamma^k (\log^c d) \frac{\sqrt{d}}{\sqrt{m}} \|a\|_2 \left\|\Sigma^{-1}\right\|_2 \|b\|_2 .$$

Since this decays exponentially in k at a rate of $\gamma < 1/2$, the sum of all terms greater than k is bounded by the kth term. As long as

$$m \gtrsim \frac{1}{\epsilon^2} d^{1+\frac{1}{k}} \log^c n, \tag{24.9}$$

we have $\gamma = \sqrt{\frac{d \log^c n}{m}} < \epsilon d^{-1/(2k)} / \log^c n$, so that

$$\sum_{k' \ge k} |a^\top V \Sigma^{-1} T^{k'} U^\top S^\top S b| \lesssim \frac{\epsilon}{\sqrt{d}} \|a\|_2 \left\|\Sigma^{-1}\right\|_2 \|b\|_2 .$$

On the other hand, by Lemma 24.3.2, increasing m by a C^k factor, we have for all k that

$$|a^\top V^\top \Sigma^{-1} U^\top S^\top S (UU^\top S^\top S)^k b| \lesssim \frac{1}{2^k} \frac{\epsilon}{\sqrt{d}} \|a\|_2 \|b\|_2 \left\|\Sigma^{-1}\right\|_2$$

with probability at least $1 - 1/\operatorname{poly}(d)$, as long as $m \gtrsim d \log^{2k+2} n \log^2(d/\epsilon)/\epsilon^2$. Since the T^k term can be expanded as a sum of 2^k terms of this form, we get that

$$\sum_{k'=1}^{k} |a^\top V \Sigma^{-1} T^k U^\top S^\top S b| \lesssim \frac{\epsilon}{\sqrt{d}} \|a\|_2 \|b\|_2 \left\|\Sigma^{-1}\right\|_2$$

with probability at least $1 - 1/\operatorname{poly}(d)$, as long as $m \gtrsim d(C \log n)^{2k+2} \log^2(d/\epsilon)/\epsilon^2$ for a sufficiently large constant C. Combining with (24.9), the result holds as long as

$$m \gtrsim \frac{d \log^c n}{\epsilon^2} \max((C \log n)^{2k+2}, d^{\frac{1}{k}})$$

for any k. Setting $k = \Theta(\sqrt{\frac{\log d}{\log \log n}})$ gives the result. □

Combining Different Matrices. In some cases it can make sense to combine different matrices that satisfy the generalization bound.

Theorem 24.3.4. Let $A \in \mathbb{R}^{n \times d}$, and let $R \in \mathbb{R}^{m \times r}$ and $S \in \mathbb{R}^{r \times n}$ be drawn from distributions of matrices that are ϵ-approximate OSEs and satisfy the generalization bound (24.6). Then RS satisfies the generalization bound with a constant factor loss in failure probability and approximation factor.

We defer the details to Appendix 24.7.

24.4 Proof of Lemma 24.3.2

Proof. Each column S_i of the subsampled randomized Hadamard transform has the same distribution as $\sigma_i S_i$, where σ_i is a random sign. It also has $\langle S_i, S_i \rangle = 1$ for all i and $|\langle S_i, S_j \rangle| \lesssim \frac{\sqrt{\log(1/\delta)}}{\sqrt{r}}$ with probability $1 - \delta$, for any δ and $i \neq j$. See, e.g., [LDFU13].

By expanding the following product into a sum, and rearranging terms, we obtain

$$\begin{aligned}
& a^\top S^\top S (UU^\top S^\top S)^k b \\
= & \sum_{i_0, j_0, i_1, j_1, \cdots, i_k, j_k} a_{i_0} b_{j_k} \sigma_{i_0} \sigma_{i_1} \cdots \sigma_{i_k} \sigma_{j_0} \sigma_{j_1} \cdots \sigma_{j_k} \\
& \cdot \langle S_{i_0}, S_{j_0} \rangle (UU^\top)_{j_0, i_1} \langle S_{i_1}, S_{j_1} \rangle \cdots (UU^\top)_{j_{k-1}, i_k} \langle S_{i_k}, S_{j_k} \rangle \\
= & \sum_{i_0, j_k} a_{i_0} b_{j_k} \sigma_{i_0} \sigma_{j_k} \sum_{j_0, i_1, j_1, \cdots, i_k} \sigma_{i_1} \cdots \sigma_{i_k} \sigma_{j_0} \sigma_{j_1} \cdots \sigma_{j_{k-1}} \\
& \cdot \langle S_{i_0}, S_{j_0} \rangle (UU^\top)_{j_0, i_1} \langle S_{i_1}, S_{j_1} \rangle \cdots (UU^\top)_{j_{k-1}, i_k} \langle S_{i_k}, S_{j_k} \rangle \\
= & \sum_{i_0, j_k} \sigma_{i_0} \sigma_{j_k} Z_{i_0, j_k}
\end{aligned}$$

where Z_{i_0, j_k} is defined to be

$$Z_{i_0, j_k} = a_{i_0} b_{j_k} \sum_{\substack{i_1, \cdots i_k \\ j_0, \cdots j_{k-1}}} \prod_{c=1}^{k} \sigma_{i_c} \prod_{c=0}^{k-1} \sigma_{j_c} \cdot \prod_{c=0}^{k} \langle S_{i_c}, S_{j_c} \rangle \prod_{c=1}^{k} (UU^\top)_{i_{c-1}, j_c}$$

Note that Z_{i_0, j_k} is independent of σ_{i_0} and σ_{j_k}. We observe that in the above expression if $i_0 = j_0$, $i_1 = j_1$, $\cdots$, $i_k = j_k$, then the sum over these indices equals $a^\top (UU^\top) \cdots (UU^\top) b = 0$, since $\langle S_{i_c}, S_{j_c} \rangle = 1$ in this case for all c. Moreover, the sum over all indices conditioned on $i_k = j_k$ is equal to 0. Indeed, in this case, the expression can be factored into the form $\zeta \cdot U^\top b$, for some random variable ζ, but $U^\top b = 0$.

Let W be a matrix with $W_{i,j} = \sigma_i \sigma_j Z_{i,j}$. We need Khintchine's inequality:

Fact 24.4.1 (Khintchine's Inequality)**.** *Let $\sigma_1, \ldots, \sigma_n$ be i.i.d. sign random variables, and let $z_1, \ldots, z_n$ be real numbers. Then there are constants $C, C' > 0$ so that*

$$\Pr\left[\left|\sum_{i=1}^{n} z_i \sigma_i\right| \geq Ct\|z\|_2\right] \leq e^{-C't^2}.$$

We note that Khintchine's inequality sometimes refers to bounds on the moment of $|\sum_i z_i\sigma_i|$, though the above inequality follows readily by applying a Markov bound to the high moments.

We apply Fact 24.4.1 to each column of W, so that if W_i is the i-th column, we have by a union bound that with probability $1 - 1/\text{poly}(n)$, $\|W_i\|_2 = O(\|Z_i\|_2\sqrt{\log n})$ simultaneously for all columns i. It follows that with the same probability, $\|W\|_F^2 = O(\|Z\|_F^2 \log n)$, that is, $\|W\|_F = O(\|Z\|_F\sqrt{\log n})$. We condition on this event in the remainder.

Thus, it remains to bound $\|Z\|_F$. By squaring Z_{i_0,j_0} and using that $\mathbf{E}[\sigma_i\sigma_j] = 1$ if $i = j$ and 0 otherwise, we have,

$$\mathop{\mathbf{E}}_{\sigma}[Z_{i_0,j_k}^2] = a_{i_0}^2 b_{j_k}^2 \sum_{\substack{i_1,\cdots i_k \\ j_0,\cdots j_{k-1}}} \prod_{c=0}^{k} \langle S_{i_c}, S_{j_c}\rangle^2 \prod_{c=1}^{k} (UU^\top)_{i_{c-1},j_c}^2 \tag{24.10}$$

We defer to Appendix 24.10 the proof that

$$\mathop{\mathbf{E}}_{S}[\|Z\|_F^2] \leq (O(d(\log n)/r) + 1)^{k-1} \cdot (d\|b\|_2^2(\log^2 n)/r^2 + \|b\|_2^2(\log n)/r)$$

Note that we also have the bound:

$$(O(d(\log n)/r) + 1)^{k-1} \leq (e^{O(d(\log n)/r)})^{k-1} \leq e^{O(kd(\log n)/r)} \leq O(1)$$

for any $r = \Omega(kd \log n)$.

Having computed the expectation of $\|Z\|_F^2$, we now would like to show concentration. Consider a specific

$$Z_{i_0,j_k} = a_{i_0} b_{j_k} \sum_{i_k} \sigma_{i_k} \langle S_{i_k}, S_{j_k} \rangle \cdots \sum_{j_1} \sigma_{j_1} (UU^\top)_{j_1,i_2} \sum_{i_1} \sigma_{i_1} \langle S_{i_1}, S_{j_1} \rangle \sum_{j_0} \sigma_{j_0} \langle S_{i_0}, S_{j_0} \rangle (UU^\top)_{j_0,i_1}.$$

By Fact 24.4.1, for each fixing of i_1, with probability $1 - 1/\mathrm{poly}(n)$, we have

$$\sum_{j_0} \sigma_{j_0} \langle S_{i_0}, S_{j_0} \rangle (UU^\top)_{j_0,i_1} = O(\sqrt{\log n}) \left(\sum_{j_0} \langle S_{i_0}, S_{j_0} \rangle^2 (UU^\top)_{j_0,i_1}^2 \right)^{\frac{1}{2}}. \tag{24.11}$$

Now, we can apply Khintchine's inequality for each fixing of j_1, and combine this with (24.11). With probability $1 - 1/\mathrm{poly}(n)$, again we have

$$\begin{aligned} & \sum_{i_1} \sigma_{i_1} \langle S_{i_1}, S_{j_1} \rangle \sum_{j_0} \sigma_{j_0} \langle S_{i_0}, S_{j_0} \rangle (UU^\top)_{j_0,i_1} \\ = & \sum_{i_1} \sigma_{i_1} \langle S_{i_1}, S_{j_1} \rangle O(\sqrt{\log n}) \left(\sum_{j_0} \langle S_{i_0}, S_{j_0} \rangle^2 (UU^\top)_{j_0,i_1}^2 \right)^{\frac{1}{2}} \\ = & O(\log n) \left(\sum_{i_1} \langle S_{i_1}, S_{j_1} \rangle^2 \sum_{j_0} \langle S_{i_0}, S_{j_0} \rangle^2 (UU^\top)_{j_0,i_1}^2 \right)^{\frac{1}{2}} \end{aligned}$$

Thus, we can apply Khintchine's inequality recursively over all the $2k$ indexes $j_0, i_1, j_1, \cdots, j_{k-1}, i_k$, from which it follows that with probability $1 - 1/\mathrm{poly}(n)$, for each such i_0, j_k, we have $Z_{i_0,j_k}^2 = O(\log^k n) \mathop{\mathbf{E}}_S [Z_{i_0,j_k}^2]$, using (24.18). We thus have with this probability, that $\|Z\|_F^2 = O(\log^k n) \mathop{\mathbf{E}}_S [\|Z\|_F^2]$, completing the proof. □

24.5 Lower bound for ℓ_2 and ℓ_∞ guarantee

We prove a lower bound for the ℓ_2 guarantee, which immediately implies a lower bound for the ℓ_∞ guarantee.

Definition 24.5.1. Given a matrix $A \in \mathbb{R}^{n \times d}$, vector $b \in \mathbb{R}^n$ and matrix $S \in \mathbb{R}^{r \times n}$, denote $x^* = A^\dagger b$. We say that an algorithm $\mathcal{A}(A, b, S)$ that outputs a vector $x' = (SA)^\dagger Sb$ "succeeds" if the following property holds: $\|x' - x^*\|_2 \lesssim \epsilon \|b\|_2 \cdot \|A^\dagger\|_2 \cdot \|Ax^* - b\|_2$.

Theorem 24.5.1. Suppose Π is a distribution over $\mathbb{R}^{m \times n}$ with the property that for any $A \in \mathbb{R}^{n \times d}$ and $b \in \mathbb{R}^n$, $\Pr_{S \sim \Pi}[\mathcal{A}(A, b, S) \text{ succeeds }] \geq 19/20$. Then $m \gtrsim \min(n, d/\epsilon^2)$.

Proof. The proof uses Yao's minimax principle. Let $\mathcal{D}$ be an arbitrary distribution over $\mathbb{R}^{n \times (d+1)}$, then $\mathop{\mathbb{E}}_{(A,b) \sim \mathcal{D}} \mathop{\mathbb{E}}_{S \sim \Pi}[\mathcal{A}(A, b, S) \text{ succeeds }] \geq 1 - \delta$. Switching the order of probabilistic quantifiers, an averaging argument implies the existence of a fixed matrix $S_0 \in \mathbb{R}^{m \times n}$ such that

$$\mathop{\mathbb{E}}_{(A,b) \sim \mathcal{D}}[\mathcal{A}(A, b, S_0) \text{ succeeds }] \geq 1 - \delta.$$

Thus, we must construct a distribution $\mathcal{D}_{\text{hard}}$ such that

$$\mathop{\mathbb{E}}_{(A,b) \sim \mathcal{D}_{\text{hard}}}[\mathcal{A}(A, b, S_0) \text{ succeeds }] \geq 1 - \delta,$$

cannot hold for any $\Pi_0 \in \mathbb{R}^{m \times n}$ which does not satisfy $m = \Omega(d/\epsilon^2)$. The proof can be split into three parts. First, we prove a useful property. Second, we prove a lower bound for the case $\text{rank}(S) \geq d$. Third, we show why $\text{rank}(S) \geq d$ is necessary.

(I) We show that $[SA, Sb]$ are independent Gaussian, if both $[A, b]$ and S are or-

thonormal matrices. We can rewrite SA in the following sense,

$$\begin{aligned}
\underbrace{S}_{m\times n}\cdot\underbrace{A}_{n\times d} &= \underbrace{S}_{m\times n}\underbrace{R}_{n\times n}\underbrace{R^\top}_{n\times n}\underbrace{A}_{n\times d} \\
&= S\begin{bmatrix} S^\top & \overline{S}^\top \end{bmatrix}\begin{bmatrix} S \\ \overline{S} \end{bmatrix} A \\
&= \begin{bmatrix} I_m & 0 \end{bmatrix}\begin{bmatrix} S \\ \overline{S} \end{bmatrix} A \\
&= \begin{bmatrix} I_m & 0 \end{bmatrix}\underbrace{\widetilde{A}}_{n\times d} \\
&= \underbrace{\widetilde{A}_m}_{m\times d}
\end{aligned} \tag{24.12}$$

where $\overline{S}$ is the complement of the orthonormal basis S, I_m is a $m \times m$ identity matrix, and $\widetilde{A}_m$ is the left $m \times d$ submatrix of $\widetilde{A}$. Thus, using [Jia06] as long as $m = o(\sqrt{n})$ (because of $n = \Omega(d^3)$) the total variation distance between $[SA, Sb]$ and a random Gaussian matrix is small, i.e.,

$$D_{TV}([SA, Sb], H) \leq 0.01 \tag{24.13}$$

where each entry of H is i.i.d. Gaussian $\mathcal{N}(0, 1/n)$.

(II) Here we prove the theorem in the case when S has rank $r \geq d$ (we will prove this is necessary in part III. Writing $S = U\Sigma V^\top$ in its SVD, we have

$$\underbrace{S}_{m\times n}A = \underbrace{U}_{m\times r}\underbrace{\Sigma}_{r\times r}\underbrace{V^\top}_{r\times n}RR^\top A = U\Sigma G \tag{24.14}$$

where $R = \begin{bmatrix} V & \overline{V} \end{bmatrix}$. By a similar argument in Equation (24.12), as long as $r = o(\sqrt{n})$ we have that G also can be approximated by a Gaussian matrix, where each entry is sampled from i.i.d. $\mathcal{N}(0, 1/n)$. Similarly, $Sb = U\Sigma h$, where h also can be approximated by a Gaussian matrix, where each entry is sampled from i.i.d. $\mathcal{N}(0, 1/n)$.

Since U has linearly independent columns, $(U\Sigma G)^\dagger U\Sigma h = (\Sigma G)^\dagger U^\top U\Sigma h = (\Sigma G)^\dagger \Sigma h$.

The $r \times d$ matrix G has SVD $G = \underbrace{R}_{r\times d}\underbrace{\widetilde{\Sigma}}_{d\times d}\underbrace{T}_{d\times d}$, and applying the pseudo-inverse property again, we have

$$\begin{aligned}
\|(SA)^\dagger Sb\|_2 &= \|(\Sigma G)^\dagger \Sigma h\|_2 \\
&= \|(\Sigma R\widetilde{\Sigma}T)^\dagger \Sigma h\|_2 \\
&= \|T^\dagger(\Sigma R\widetilde{\Sigma})^\dagger \Sigma h\|_2 \\
&= \|(\Sigma R\widetilde{\Sigma})^\dagger \Sigma h\|_2 \\
&= \|\widetilde{\Sigma}^\dagger(\Sigma R)^\dagger \Sigma h\|_2,
\end{aligned}$$

where the the first equality follows by Equation (24.14), the second equality follows by the SVD of G, the third and fifth equality follow by properties of the pseudo-inverse[1] when T has orthonormal rows and $\widetilde{\Sigma}$ is a diagonal matrix, and the fourth equality follows since $\|T^\dagger\|_2 = 1$ and T is an orthonormal basis.

Because each entry of $G = R\widetilde{\Sigma}T \in \mathbb{R}^{r\times d}$ is sampled from an i.i.d. Gaussian $\mathcal{N}(0,1)$, using the result of [Ver10] we can give an upper bound for the maximum singular value of G: $\|\widetilde{\Sigma}\| \lesssim \sqrt{\frac{r}{n}}$ with probability at least .99. Thus,

$$\begin{aligned}
\|\widetilde{\Sigma}^\dagger(\Sigma R)^\dagger \Sigma h\|_2 &\geq \sigma_{\min}(\widetilde{\Sigma}^\dagger)\cdot\|(\Sigma R)^\dagger \Sigma h\|_2 \\
&= \frac{1}{\sigma_{\max}(\widetilde{\Sigma})}\|(\Sigma R)^\dagger \Sigma h\|_2 \\
&\gtrsim \sqrt{n/r}\|(\Sigma R)^\dagger \Sigma h\|_2.
\end{aligned}$$

[1] https://en.wikipedia.org/wiki/Moore-Penrose_pseudoinverse

Because h is a random Gaussian vector which is independent of $(\Sigma R)^\dagger \Sigma$, by Claim 24.5.2, $\mathbb{E}_h[\|(\Sigma R)^\dagger \Sigma h\|_2^2] = \frac{1}{n} \cdot \|(\Sigma R)^\dagger \Sigma\|_F^2$, where each entry of h is sampled from i.i.d. Gaussian $\mathcal{N}(0, 1/n)$. Then, using the Pythagorean Theorem,

$$\begin{aligned}
\|(\Sigma R)^\dagger \Sigma\|_F^2 &= \|(\Sigma R)^\dagger \Sigma R R^\top\|_F^2 + \|(\Sigma R)^\dagger \Sigma (I - RR^\top)\|_F^2 \\
&\geq \|(\Sigma R)^\dagger \Sigma R R^\top\|_F^2 \\
&= \|(\Sigma R)^\dagger \Sigma R\|_F^2 \\
&= \text{rank}(\Sigma R) \\
&= \text{rank}(SA) \\
&= d.
\end{aligned}$$

Thus, $\|x' - x^*\|_2 \gtrsim \sqrt{d/r} \geq \sqrt{d/m} = \epsilon$.

(III) Now we show that we can assume that $\text{rank}(S) \geq d$.

We sample A, b based on the following distribution $\mathcal{D}_{\text{hard}}$: with probability $1/2$, A, b are sampled from $\mathcal{D}_1$; with probability $1/2$, A, b are sampled from $\mathcal{D}_2$. In distribution $\mathcal{D}_1$, A is a random orthonormal basis and d is always orthogonal to A. In distribution $\mathcal{D}_2$, A is a $d \times d$ identity matrix in the top-d rows and 0s elsewhere, while b is a random unit vector. Then, for any (A, b) sampled from $\mathcal{D}_1$, S needs to work with probability at least $9/10$. Also for any (A, b) sampled from $\mathcal{D}_2$, S needs to work with probability at least $9/10$. The latter two statements follow since overall S succeeds on $\mathcal{D}_{\text{hard}}$ with probability at least $19/20$.

Consider the case where A, b are sampled from distribution $\mathcal{D}_2$. Then $x^* = b$ and $\text{OPT} = 0$. Then consider x' which is the optimal solution to $\min_x \|SAx - Sb\|_2^2$, so $x' = (SA)^\dagger Sb = (S_L)^\dagger S_L b$, where S can be decomposed into two matrices $S_L \in \mathbb{R}^{r \times d}$ and $S_R \in$

$\mathbb{R}^{r\times(n-d)}$, $S = \begin{bmatrix} S_L & S_R \end{bmatrix}$. Plugging x' into the original regression problem, $\|Ax' - b\|_2^2 = \|A(S_L)^\dagger S_L b - b\|_2^2$, which is at most $(1+\epsilon)\,\mathrm{OPT} = 0$. Thus $\mathrm{rank}(S_L)$ is d. Since S_L is a submatrix of S, the rank of S is also d. □

It remains to define several tools which are used in the main proof of the lower bound.

Claim 24.5.2. *For any matrix $A \in \mathbb{R}^{n\times d}$, if each entry of a vector $g \in \mathbb{R}^d$ is chosen from an i.i.d Gaussian $\mathcal{N}(0,\sigma^2)$, then $\mathop{\mathbb{E}}_g[\|Ag\|_2^2] = \sigma^2\|A\|_F^2$.*

Proof.

$$\begin{aligned}
\mathop{\mathbb{E}}_g[\|Ag\|_2^2] &= \mathop{\mathbb{E}}_g\left[\sum_{i=1}^n (\sum_{j=1}^d A_{ij}g_j)^2\right] \\
&= \mathop{\mathbb{E}}_g\left[\sum_{i=1}^n (\sum_{j=1}^d A_{ij}^2 g_j^2 + \sum_{j\neq j'} A_{ij}A_{ij'}g_j g_{j'})\right] \\
&= \sum_{i=1}^n \sum_{j=1}^d A_{ij}^2\sigma^2 \\
&= \sigma^2\|A\|_F^2.
\end{aligned}$$

□

Let $g_1, g_2, \cdots, g_t$ be i.i.d. $\mathcal{N}(0,1)$ random variables. The random variables $\sum_{i=1}^t g_i^2$ are $\mathcal{X}^2$ with t degree of freedom. Furthermore, the tail bounds are known (see Lemma A.1.6).

Definition 24.5.2. Given a matrix $A \in \mathbb{R}^{n\times d}$, vector $b \in \mathbb{R}^n$ and matrix $S \in \mathbb{R}^{r\times n}$, denote $x^* = A^\dagger b$. We say that an algorithm $\mathcal{B}(A,b,S)$ that outputs a vector $x' = (SA)^\dagger Sb$ "succeeds" if the following property holds:

$$\|x' - x^*\|_\infty \lesssim \frac{\epsilon}{\sqrt{d}}\|b\|_2 \cdot \|A^\dagger\|_2 \cdot \|Ax^* - b\|_2.$$

Applying $\|x' - x\|_\infty \geq \frac{1}{\sqrt{d}}\|x' - x\|_2$ to Theorem 24.5.1 ,we obtain the ℓ_∞ lower bound as a corollary,

Corollary 24.5.3. *Suppose* Π *is a distribution over* $\mathbb{R}^{m\times n}$ *with the property that for any* $A \in \mathbb{R}^{n\times d}$ *and* $b \in \mathbb{R}^n$,

$$\Pr_{S\sim\Pi}[\mathcal{B}(A, b, S) \text{ succeeds }] \geq 9/10.$$

Then $m \gtrsim \min(n, d/\epsilon^2)$.

24.6 Proof for Gaussian case

Lemma 24.6.1. *If the entries of* $S \in \mathbb{R}^{m\times n}$ *are i.i.d.* $N(0, 1/m)$, $m = O(d/\epsilon^2)$, *and* $U^\top b = 0$, *then*

$$|a^\top (SA)^\dagger Sb| \lesssim \frac{\epsilon\sqrt{\log d}}{\sqrt{d}} \|a\|_2 \|b\|_2 \left\|\Sigma^{-1}\right\|_2$$

for any vectors a, b *with probability* $1 - 1/\mathrm{poly}(d)$.

Proof. With probability 1, the matrix SA has linearly independent columns, and so $(SA)^\dagger$ is

$$\begin{aligned}
&= (A^\top S^\top SA)^{-1} A^\top S^\top \\
&= (V\Sigma U^\top S^\top SU\Sigma V^\top)^{-1} V\Sigma U^\top S^\top \\
&= V\Sigma^{-1}(U^\top S^\top SU)^{-1}\Sigma^{-1} V^\top V\Sigma U^\top S^\top \\
&= V\Sigma^{-1}(U^\top S^\top SU)^{-1} U^\top S^\top.
\end{aligned}$$

Hence, we would like to bound

$$X = a^\top V\Sigma^{-1}(U^\top S^\top SU)^{-1} U^\top S^\top Sb.$$

It is well-known (stated, for example, explicitly in Theorem 2.3 of [Woo14a]) that with probability $1-\exp(-d)$, the singular values of SU are $(1\pm\epsilon)$ for $m = O(d/\epsilon^2)$. We condition on this event. It follows that

$$\begin{aligned} & \|V\Sigma^{-1}(U^\top S^\top SU)^{-1}U^\top S\|_2 \\ = \; & \|\Sigma^{-1}(U^\top S^\top SU)^{-1}U^\top S\|_2 \\ \leq \; & \|\Sigma^{-1}\|_2\|(U^\top S^\top SU)^{-1}\|_2\|U^\top S\|_2 \\ \leq \; & \|\Sigma^{-1}\|_2 \cdot \frac{1}{1-\epsilon} \cdot (1+\epsilon) \\ = \; & O(\|\Sigma^{-1}\|_2), \end{aligned}$$

where the first equality uses that V is a rotation, the first inequality follows by sub-multiplicativity, and the second inequality uses that the singular values of SU are in the range $[1-\epsilon, 1+\epsilon]$. Hence, with probability $1-\exp(-d)$,

$$\|a^\top V\Sigma^{-1}(U^\top S^\top SU)^{-1}U^\top S^\top\|_2 = O(\|\Sigma^{-1}\|_2\|a\|_2). \tag{24.15}$$

The main observation is that since $U^\top b = 0$, SU is statistically independent from Sb. Hence, Sb is distributed as $N(0, \|b\|_2^2 I_m)$, conditioned on the vector $a^\top V\Sigma^{-1}(U^\top S^\top SU)^{-1}U^\top S^\top$. It follows that conditioned on the value of $a^\top V\Sigma^{-1}(U^\top S^\top SU)^{-1}U^\top S^\top$, X is distributed as

$$N(0, \|b\|_2^2\|a^\top V\Sigma^{-1}(U^\top S^\top SU)^{-1}U^\top S^\top\|_2^2/m),$$

and so using (24.15) , with probability $1 - 1/\mathrm{poly}(d)$, we have

$$|X| = O(\epsilon\sqrt{\log d}\|a\|_2\|b\|_2\|\Sigma^{-1}\|_2/\sqrt{d}).$$

□

24.7 Combining Different Matrices

In some cases it can make sense to combine different matrices that satisfy the generalization bound.

Theorem 24.3.4. Let $A \in \mathbb{R}^{n \times d}$, and let $R \in \mathbb{R}^{m \times r}$ and $S \in \mathbb{R}^{r \times n}$ be drawn from distributions of matrices that are ϵ-approximate OSEs and satisfy the generalization bound (24.6). Then RS satisfies the generalization bound with a constant factor loss in failure probability and approximation factor.

Proof. For any vectors a, b, and $x^* = A^\dagger b$ we want to show

$$|a^\top (RSA)^\dagger RSb - a^\top x^*| \lesssim \frac{\epsilon}{\sqrt{d}} \|a\|_2 \|b - Ax^*\|_2 \left\|A^\dagger\right\|_2$$

As before, it suffices to consider the $x^* = 0$ case. We have with probability $1 - \delta$ that

$$|a^\top (SA)^\dagger Sb| \lesssim \frac{\epsilon}{\sqrt{d}} \|a\|_2 \|b\|_2 \left\|A^\dagger\right\|_2;$$

suppose this happens. We also have by the properties of R, applied to SA and Sb, that

$$|a^\top (RSA)^\dagger RSb - a^\top (SA)^\dagger Sb| \lesssim \frac{\epsilon}{\sqrt{d}} \|a\|_2 \|Sb\|_2 \left\|(SA)^\dagger\right\|_2.$$

Because S is an OSE, we have $\|Sb\|_2 \leq (1 + \epsilon)$ and $\left\|(SA)^\dagger\right\|_2 \gtrsim (1 - \epsilon) \left\|A^\dagger\right\|_2$. Therefore

$$|a^\top (RSA)^\dagger RSb| \lesssim \frac{\epsilon}{\sqrt{d}} \|a\|_2 \|b\|_2 \left\|A^\dagger\right\|_2$$

□

We describe a few of the applications of combining sketches.

24.7.1 Removing dependence on n via Count-Sketch

One of the limitations of the previous section is that the choice of k depends on n. To prove that theorem, we have to assume that $\log d > \log\log n$. Here, we show an approach to remove that assumption.

The main idea is instead of applying matrix $S \in \mathbb{R}^{m \times n}$ to matrix $A \in \mathbb{R}^{n \times d}$ directly, we pick two matrices $S \in \mathbb{R}^{m \times \mathrm{poly}(d)}$ and $C \in \mathbb{R}^{\mathrm{poly}(d) \times n}$, e.g. S is FastJL matrix and C is Count-Sketch matrix with $s = 1$. We first compute $C \cdot A$, then compute $S \cdot (CA)$. The benefit of these operations is S only needs to multiply with a matrix (CA) that has $\mathrm{poly}(d)$ rows, thus the assumption we need is $\log d > \log\log(\mathrm{poly}(d))$ which is always true. The reason for choosing C as a Count-Sketch matrix with $s = 1$ is: (1) $\mathrm{nnz}(CA) \leq \mathrm{nnz}(A)$ (2) The running time is $O(\mathrm{poly}(d) \cdot d + \mathrm{nnz}(A))$.

24.7.2 Combining Gaussians and SRHT

By combining Gaussians with SRHT matrices, we can embed into the optimal dimension $O(d/\epsilon^2)$ with fast $\widetilde{O}(nd \log n + d^\omega/\epsilon^4)$ embedding time.

24.7.3 Combining all three

By taking Gaussians times SRHT times Count-Sketch, we can embed into the optimal dimension $O(d/\epsilon^2)$ with fast $O(\mathrm{nnz}(A) + d^4 \mathrm{poly}(\frac{1}{\epsilon}, \log d))$ embedding time.

24.8 Count-Sketch does not obey the ℓ_∞ guarantee

Here we demonstrate an A and a b such that Count-Sketch will not satisfy the ℓ_∞ guarantee with constant probability, so such matrices cannot satisfy the generalization guar-

antee (24.6) with high probability.

Theorem 24.8.1. Let $S \in \mathbb{R}^{m \times n}$ be drawn as a Count-Sketch matrix with s nonzeros per column. There exists a matrix $A \in \mathbb{R}^{n \times d}$ and $b \in \mathbb{R}^n$ such that, if $s^2 d \lesssim m \lesssim \sqrt{d^3 s}$, then the "true" solution $x^* = A^\dagger b$ and the approximation $x' = (SA)^\dagger Sb$ have large ℓ_∞ distance with constant probability:

$$\|x' - x^*\|_\infty \gtrsim \sqrt{\frac{d}{ms}} \|b\|_2 .$$

Plugging in $m = d^{1.5}$ and $s = d^{0.25}$ we find that

$$\|x' - x^*\|_\infty \gtrsim 1/d^{3/8} \|b\|_2 \gg 1/\sqrt{d} \|b\|_2 ,$$

even though such a matrix is an OSE with probability exponential in s. Therefore there exists a constant c for which this matrix does not satisfy the generalization guarantee (24.6) with $1 - \frac{c}{d}$ probability.

Proof. We choose the matrix A to be the identity on its top d rows: $A = \begin{bmatrix} I_d \\ 0 \end{bmatrix}$. Choose some $\alpha \geq 1$, set the value of the first d coordinates of vector b to be $\frac{1}{\sqrt{d}}$ and set the value to be $1/\sqrt{\alpha}$ for the next α coordinates, with the remaining entries all zero. Note that $\|b\|_2 = \sqrt{2}$, $x^* = (1/\sqrt{d}, \ldots, 1/\sqrt{d})$, and $\|Ax^* - b\|_2 = 1$.

Let S_k denote the kth column vector of matrix $S \in \mathbb{R}^{m \times n}$. We define two events, Event I, $\forall k' \in [d]$ and $k' \neq k$, we have $\text{supp}(S_{k'}) \cap \text{supp}(S_k) = \emptyset$; Event II, $\exists$ a unique $k' \in \{d+1, d+2, \cdots, d+\alpha\}$ such that $|\text{supp}(S_{k'}) \cap \text{supp}(S_k)| = 1$, and all other k' have $\text{supp}(S_{k'}) \cap \text{supp}(S_k) = \emptyset$. Using Claim 24.8.2, with probability at least .99 there exists a k for which both events hold.

Given the constructions of A and b described early, it is obvious that

$$Ax - b = \left[x_1 - \tfrac{1}{\sqrt{d}}, \cdots, x_d - \tfrac{1}{\sqrt{d}}, -\tfrac{1}{\sqrt{\alpha}}, \cdots, -\tfrac{1}{\sqrt{\alpha}}, 0, \cdots, 0\right]^\top.$$

Conditioned on event I and II are holding, then denote $\text{supp}(S_j) = \{i_1, i_2, \cdots, i_s\}$. Consider the terms involving x_j in the quadratic form

$$\min_x \|SAx - Sb\|_2^2.$$

it can be written as $(s-1)(x_j - 1/\sqrt{d})^2 + (x_j - 1/\sqrt{d} \pm 1/\sqrt{\alpha})^2$. Hence the optimal x' will have $x'_j = \frac{1}{\sqrt{d}} \pm \frac{1}{s\sqrt{\alpha}}$, which is different from the desired $1/\sqrt{d}$ by $\frac{1}{s\sqrt{\alpha}}$. Plugging in our requirement of $\alpha \approx m^2/(s^3d^2)$, we have

$$\|x' - x^*\|_\infty \geq \frac{1}{s\sqrt{\alpha}} \gtrsim c\sqrt{\frac{sd^2}{m^2}} \gtrsim \frac{1}{\sqrt{d}}$$

where the last inequality follows by $m \lesssim \sqrt{sd^3}$. Thus, we get the result. □

Claim 24.8.2. *If $m = \Omega(s^2 d)$, $m = o(d^2)$, $\alpha < d$, and $\alpha = O(\frac{m^2}{s^3 d^2})$, with probability at least .99 there exists a $k \in [d]$ for which both event I and II hold.*

Proof. If $m = \Omega(s^2 d)$, then for any i in $\{1, 2, ..., d\}$, let X_i be an indicator that the entries of column i are disjoint from all i' in $[d]\backslash\{i\}$. Then $\mathbb{E}[X_i] \geq .9999$, so by Markov's inequality, with probability .99, we have $.99d$ columns having this property (indeed, the expected value of $d - X$ is at most $.0001d$, so $\Pr[d - X \geq .01d] \leq \frac{\mathbb{E}[d-X]}{.01d} \leq \frac{.0001d}{.01d} = .01$). Define Event E to be that $.99d$ columns of first d columns have the property that the entries of that column

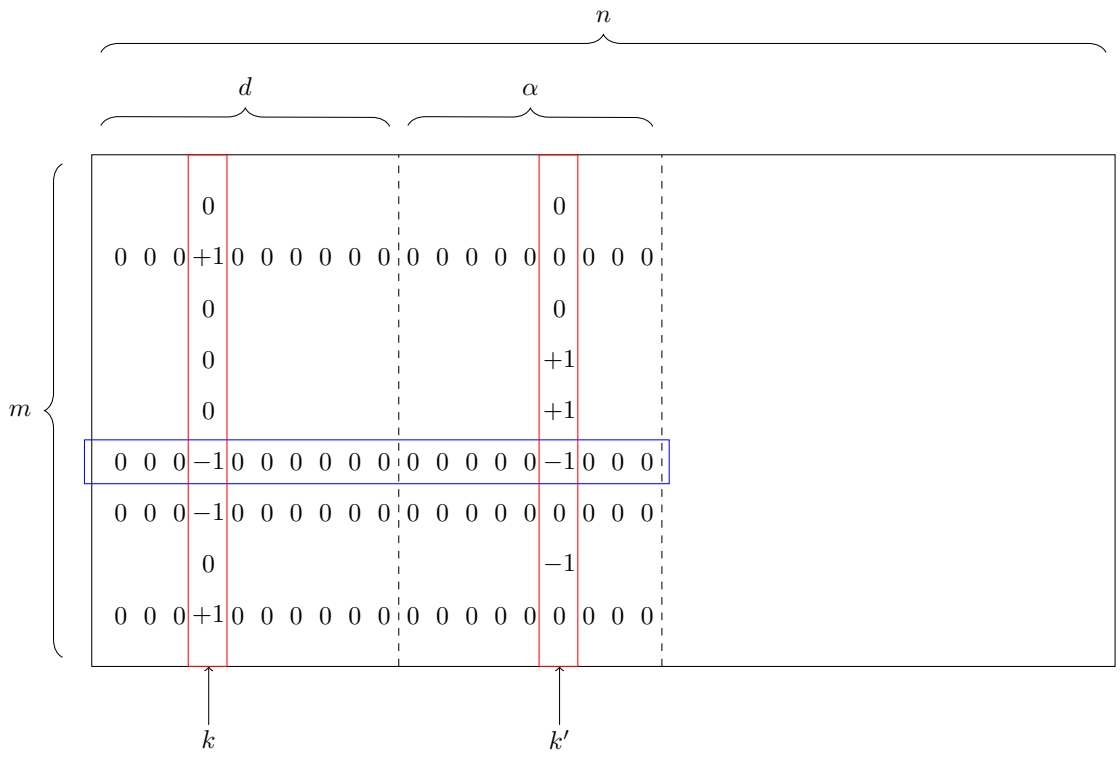

Figure 24.2: Count Sketch matrix $S \in \mathbb{R}^{m \times n}$. Event I, for any $k' \in [d]$ and $k' \neq k$, $\text{supp}(S_k) \cap \text{supp}(S_{k'}) = \emptyset$. Event II, there exists a unique $k' \in \{d+1, d+2, \cdots, d+\alpha\}$ such that S_k and $S_{k'}$ intersect at exactly one location(row index).

are disjoint from all the other $d-1$ columns. Let S be the set of these $.99d$ columns. Let N be the union of supports of columns in S.

Each column i in $\{d+1, ..., d+\alpha\}$ chooses s non-zero entries. Define event $F($ which is similar as event $E)$ to be that $.99\alpha$ columns of the next α columns have the property that the entries of that column are disjoint from all the other $\alpha - 1$ columns. By the same argument, since $\alpha < d$, with probability .99, we have $.99\alpha$ columns in $\{d+1, ..., d+\alpha\}$ being disjoint from other columns in $\{d+1, ..., d+\alpha\}$. Condition on event F holding. Let L be the multiset union of supports of all columns in $\{d+1, ..., d+\alpha\}$. Then L has size $\alpha \cdot s$. Let

M be the union of supports of all columns in $\{d+1, ..., d+\alpha\}$, that is, the set union rather than the multiset union. Note that $|M| \geq .99\alpha \cdot s$ because of $.99\alpha$ columns are disjoint from each other.

The intersection size x of N and M is hyper-geometrically distributed with expectation

$$\mathbb{E}[x] = \frac{s|S| \cdot |M|}{m}.$$

By a lower tail bound for the hypergeometric distribution [2] ,

$$\Pr[x \leq (p-t)n] \leq \exp(-2t^2 n),$$

where $p = s \cdot |S|/m$ and $n = |M|$, so

$$\Pr[x \leq \mathbb{E}[x] - t \cdot |M|] \leq \exp(-2t^2 \cdot |M|) \leq 0.01,$$

where the last inequality follows by setting $t = \Theta(1/\sqrt{|M|})$. Thus, we get with probability .99, the intersection size is at least $\frac{s|S| \cdot |M|}{m} - \Theta(\sqrt{|M|})$.

Now let W be the distinct elements in $L \backslash M$, so necessarily $|W| \leq .01\alpha \cdot s$. By an upper tail bound for the hypergeometric distribution, the intersection size y of W and N satisfies

$$\Pr[y \geq (p+t)n] \leq \exp(-2t^2 n),$$

where $p = s \cdot |S|/m$ and $n = |W|$, we again get

$$\Pr[y \geq \mathbb{E}[y] + t \cdot |W|] \leq \exp(-2t^2 \cdot |W|).$$

[2] https://en.wikipedia.org/wiki/Hypergeometric_distribution

If $|W| = 0$, then $y = 0$. Otherwise, we can set $t = \Theta(1/\sqrt{|W|})$ so that this probability is less than .01, and we get with probability .99, the intersection size y is at most $s \cdot |S| \cdot |W|/m + \Theta(\sqrt{|W|})$. Note that we have that $\Theta(\sqrt{|M|})$ and $\Theta(\sqrt{|W|})$ are bounded by $\Theta(\sqrt{s \cdot \alpha})$. Setting $\alpha = O(\frac{m^2}{s^3 d^2})$ suffices to ensure y is at most $(1.01)s \cdot |S| \cdot |W|/m$, and earlier that x is at least $.99 \cdot s \cdot |S| \cdot |M|/m$.

The probability one of the $|S|$ blocks in N has two or more intersections with M is less than $\binom{x}{2}$ times the probability two random distinct items in the intersection land in the block. This probability is

$$\frac{\binom{x}{2} \cdot \binom{s}{2}}{\binom{s \cdot |S|}{2}} = \Theta(x^2/|S|^2) = \Theta(x^2/d^2) = \Theta(m^2/(d^4 s^2)).$$

So the expected number of such blocks is $\Theta(m^2 sd/(d^4 s^2)) = \Theta(m^2/(d^3 s))$ which is less than $(.99 \cdot s \cdot |S| \cdot |M|)/(2m) \leq X/2$ if $m = o(d^2)$, which we have. So, there are at least $x/2$ blocks which have intersection size exactly 1 with N. Note that the number of intersections of the $|S|$ blocks with W is at most y, which is at most $(1.01)s \cdot |S| \cdot |W|/m \leq (1.01)s \cdot |S| \cdot \frac{1}{99} \cdot |M|/m < x/2$, and therefore there exists a block, that is, a column among the first d columns, which intersects M in exactly one position and does not intersect W. This is our desired column. Thus, we complete the proof. □

24.9 Leverage score sampling does not obey the ℓ_∞ guarantee

Not only does Count-Sketch fail, but so does leverage score sampling, which is a technique that takes a subsample of rows of A with rescaling. In this section we show an A and a b such that leverage score sampling will not satisfy the ℓ_∞ guarantee. We start with a formal definition of leverage scores.

Definition 24.9.1 (Leverage Scores)**.** Given an arbitrary $n \times d$ matrix A, with $n > d$, let U denote the $n \times d$ matrix consisting of the d left singular vectors of A, let $U_{(i)}$ denote the $i-$th row of the matrix U, so $U_{(i)}$ is a row vector. Then the leverage scores of the rows of A are given by $l_i = \|U_{(i)}\|_2^2$, for $i \in [n]$.

The leverage score sampling matrix can be thought of as a square diagonal matrix $D \in \mathbb{R}^{n \times n}$ with diagonal entries chosen from some distribution. If $D_{ii} = 0$, it means we do not choose the i-th row of matrix A., If $D_{ii} > 0$, it means we choose that row of the matrix A and also rescale that row. We show that the leverage score sampling matrix cannot achieve ℓ_∞ guarantee, nor can it achieve our notion of generalization error.

Theorem 24.9.1. Let $D \in \mathbb{R}^{n \times n}$ be a leverage score sampling matrix with m nonzeros on the diagonal. There exists a matrix $A \in \mathbb{R}^{n \times d}$ and a vector $b \in \mathbb{R}^n$ such that, if $m \lesssim d\sqrt{d}$, then the "true" solution $x^* = A^\dagger b$ and the approximation $x' = (DA)^\dagger Db$ have large ℓ_∞ distance with constant probability:

$$\|x' - x^*\|_\infty \gtrsim \frac{1}{\sqrt{d}} \|b\|_2 .$$

Therefore there exists a constant c for which this matrix does not satisfy the generalization guarantee (24.6) with $1 - \frac{c}{d}$ probability.

Proof. We choose the matrix A to be the identity on its top d rows, and L scaled identity matrices $\frac{1}{\sqrt{\alpha d}} I_d$ for the next dL rows, where L satisfies $\frac{1}{d} + \frac{1}{\alpha d} L = 1$ (to normalize each column of A), which implies $L = \alpha(d-1)$. Choose some $\beta \in [1, d)$. Set the value of the first d coordinates of vector b to be $\frac{1}{\sqrt{d}}$ and set the value to be $\frac{1}{\sqrt{\beta}}$ for the next β coordinates, with the remaining entries all zero. Note that $\|b\|_2 = \sqrt{2}$.

First, we compute $\|Ax-b\|_2^2$. Because β is less than d, there are two kinds of x_j: one involves the following term,

$$(\frac{1}{\sqrt{d}}x_j - \frac{1}{\sqrt{d}})^2 + (L-1)(\frac{1}{\sqrt{\alpha d}}x_j)^2, \tag{24.16}$$

where the optimal x_j should be set to $1/d$. The other involves the term:

$$(\frac{1}{\sqrt{d}}x_j - \frac{1}{\sqrt{d}})^2 + (\frac{1}{\sqrt{\alpha d}}x_j - \frac{1}{\sqrt{\beta}})^2 + (L-1)(\frac{1}{\sqrt{\alpha d}}x_j)^2, \tag{24.17}$$

where the optimal x_j should be set to $1/d + 1/\sqrt{\alpha\beta d}$. Because we are able to choose α, β such that $\alpha\beta \gtrsim d$, then

$$x_j = 1/d + 1/\sqrt{\alpha\beta d} \lesssim 1/d.$$

Second, we compute $\|DAx - Db\|_2^2$. With high probability, there exists a j satisfying Equation (24.17), but after applying leverage score sampling, the middle term of Equation (24.17) is removed. Let $p_1 = \frac{1}{d}$ denote the leverage score of each of the top d rows of A, and let $p_2 = \frac{1}{\alpha d}$ denote the leverage score of each of the next Ld rows of A. We need to discuss the cases $m > d$ and $m \leq d$ separately.

If $m > d$, then the following term involves x_j,

$$\begin{aligned}
& (\frac{1}{\sqrt{p_1}}\frac{1}{\sqrt{d}}x_j - \frac{1}{\sqrt{p_1}}\frac{1}{\sqrt{d}})^2 + \frac{m-d}{d}\cdot(\frac{1}{\sqrt{p_2}}\frac{1}{\sqrt{\alpha d}}x_j)^2 \\
= \; & \frac{1}{p_1}(\frac{1}{\sqrt{d}}x_j - \frac{1}{\sqrt{d}})^2 + \frac{m-d}{d}\cdot\frac{1}{p_2}(\frac{1}{\sqrt{\alpha d}}x_j)^2 \\
= \; & d\left((\frac{1}{\sqrt{d}}x_j - \frac{1}{\sqrt{d}})^2 + \frac{m-d}{d}\alpha(\frac{1}{\sqrt{\alpha d}}x_j)^2\right).
\end{aligned}$$

where the optimal x_j should be set to

$$\begin{aligned} x_j &= \frac{1/d}{1/d + (m-d)\alpha/(\alpha d^2)} \\ &= \frac{1}{1 + (m-d)/d} \\ &\gtrsim \frac{1}{(m-d)/d} \\ &\gg \frac{1}{\sqrt{d}}. \qquad \text{by } \; m \ll d\sqrt{d} \end{aligned}$$

If $m \leq d$, then the term involving x_j is $(\frac{1}{\sqrt{p_1}}\frac{1}{\sqrt{d}}x_j - \frac{1}{\sqrt{p_1}}\frac{1}{\sqrt{d}})^2$ where the optimal x_j should be set to be $1 \gg 1/\sqrt{d}$.

Third, we need to compute $\|Ax^* - b\|_2^2$ and $\sigma_{\min}(A)$. It is easy to see that $\sigma_{\min}(A)$ because A is an orthonormal matrix. The upper bound for $\|Ax^* - b\|_2^2 = 2$, and the lower bound is also a constant, which can be proved in the following way:

$$\|Ax^* - b\|_2^2 = \sum_{j=1}^{\beta}(24.16) + \sum_{j=\beta+1}^{d}(24.17) \geq d(\frac{1}{\sqrt{d}}\frac{1}{d} - \frac{1}{\sqrt{d}})^2 \gtrsim d \cdot \frac{1}{d} = 1.$$

□

24.10 Bounding $\mathbb{E}[\|Z\|_F^2]$

Before getting into the proof details, we define the key property of S being used in the rest of the proofs.

Definition 24.10.1 (All Inner Product Small(AIPS) Property)**.** For any matrix $S \in \mathbb{R}^{r \times n}$, if for all $i, j \in [n]$ with $i \neq j$ we have

$$|\langle S_i, S_j \rangle| = O(\sqrt{\log n}/\sqrt{r}),$$

we say that S satisfies the "AIPS" property.

Claim 24.10.1. *If $S \in \mathbb{R}^{r \times n}$ is a subsampled Hadamard transform matrix, then the* AIPS *property holds with probability at least* $1 - 1/\operatorname{poly}(n)$.

Proof. From the structure of S, for any $i \neq j$, we have with probability $1 - 1/\operatorname{poly}(n)$ such that $|\langle S_i, S_j \rangle| = O(\sqrt{\log n}/\sqrt{r})$. Applying a union bound over $O(n^2)$ pairs, we obtain that

$$\Pr[\text{ AIPS holds }] \geq 1 - 1/\operatorname{poly}(n).$$

□

The main idea for bounding $\mathbb{E}[\|Z\|_F^2]$ is to rewrite it as $\mathbb{E}[\|Z\|_F^2] = \mathbb{E}[\ \|Z\|_F^2 \mid \text{AIPS holds }] + \mathbb{E}[\ \|Z\|_F^2 \mid \text{AIPS does not hold }]$. Because Pr[AIPS does not hold] is at most $1/\operatorname{poly}(n)$, the first term dominates the second term, which means we only need to pay attention to the first term. We repeatedly apply this idea until all the S are removed.

We start by boundinbg $\mathbb{E}[\|Z\|_F^2]$ by squaring Z_{i_0,j_0} and using that $\mathbb{E}[\sigma_i \sigma_j] = 1$ if $i = j$ and 0 otherwise. Then, we obtain,

$$\mathop{\mathbb{E}}_{\sigma}[Z_{i_0,j_k}^2] = a_{i_0}^2 b_{j_k}^2 \sum_{i_1,\cdots i_k, j_0, \cdots j_{k-1}} \prod_{c=0}^{k} \langle S_{i_c}, S_{j_c} \rangle^2 \prod_{c=1}^{k} (UU^\top)_{i_{c-1},j_c}^2. \tag{24.18}$$

We thus have,

$$\sum_{i_0, j_k, j_k \neq i_k} a_{i_0}^2 \langle S_{i_0}, S_{j_0} \rangle^2 b_{j_k}^2 \langle S_{i_k}, S_{j_k} \rangle^2 = a_{j_0}^2 \|b\|_2^2 O((\log n)/r) + \|a\|_2^2 \|b\|_2^2 O((\log^2 n)/r^2) \stackrel{\text{def}}{=} C_{j_0},$$

where the first equality is from our conditioning, and the second equality is the definition

of C_{j_0}. Hence, $\mathop{\mathbb{E}}_{S}[\|Z\|_F^2]$ is

$$
\begin{aligned}
&= \sum_{i_1,\cdots i_k,j_0,\cdots j_{k-1}} \prod_{c=1}^{k-1} \langle S_{i_c}, S_{j_c}\rangle^2 \prod_{c=1}^{k} (UU^\top)^2_{j_{c-1},i_c} \cdot \sum_{i_0,j_k,j_k \neq i_k} a_{i_0}^2 \langle S_{i_0}, S_{j_0}\rangle^2 b_{j_k}^2 \langle S_{i_k}, S_{j_k}\rangle^2 \\
&= \sum_{i_1,\cdots i_k,j_0,\cdots j_{k-1}} \prod_{c=1}^{k-1} \langle S_{i_c}, S_{j_c}\rangle^2 \prod_{c=1}^{k} (UU^\top)^2_{j_{c-1},i_c} C_{j_0} \\
&= \sum_{i_1,\cdots i_k,j_0,\cdots j_{k-1}} \langle S_{i_{k-1}}, S_{j_{k-1}}\rangle^2 (UU^\top)^2_{j_{k-1},i_k} \cdot \prod_{c=1}^{k-2} \langle S_{i_c}, S_{j_c}\rangle^2 \prod_{c=1}^{k-1} (UU^\top)^2_{j_{c-1},i_c} C_{j_0},
\end{aligned}
$$

where the first equality follows from (24.18), the second equality by definition of C_{j_0}, and the final equality by factoring out $c = k-1$ from one product and $c = k-2$ from the other product.

The way to bound the term $\langle S_{i_{k-1}}, S_{j_{k-1}}\rangle$ is by separating the diagonal term where $i_{k-1} = j_{k-1}$ and the non-diagonal term where $i_{k-1} \neq j_{k-1}$. We now use the aforementioned property of S, namely, that $\langle S_{i_{k-1}}, S_{j_{k-1}}\rangle = 1$, if $i_{k-1} = j_{k-1}$, while for $i_{k-1} \neq j_{k-1}$, we have with probability $1 - 1/\mathrm{poly}(n)$ that $|\langle S_{i_{k-1}}, S_{j_{k-1}}\rangle| = O(\sqrt{\log n}/\sqrt{r})$ conditioned on AIPS holding.

Conditioned on AIPS holding, we can recursively reduce the number of terms in the

product:

$$
\begin{aligned}
& \|Z\|_F^2 \\
= & \sum_{i_1,\cdots i_k,j_0,\cdots j_{k-1},i_{k-1}\neq j_{k-1}} O((\log n)/r)\cdot (UU^\top)^2_{j_{k-1},i_k}\cdot \prod_{c=1}^{k-2}\langle S_{i_c},S_{j_c}\rangle^2 \prod_{c=1}^{k-1}(UU^\top)^2_{j_{c-1},i_c}C_{j_0} \\
+ & \sum_{i_1,\cdots i_k,j_0,\cdots j_{k-1},i_{k-1}=j_{k-1}} 1\cdot (UU^\top)^2_{j_{k-1},i_k}\cdot \prod_{c=1}^{k-2}\langle S_{i_c},S_{j_c}\rangle^2 \prod_{c=1}^{k-1}(UU^\top)^2_{j_{c-1},i_c}C_{j_0} \\
\leq & \sum_{i_1,\cdots i_k,j_0,\cdots j_{k-1}} O((\log n)/r)\cdot (UU^\top)^2_{j_{k-1},i_k}\cdot \prod_{c=1}^{k-2}\langle S_{i_c},S_{j_c}\rangle^2 \prod_{c=1}^{k-1}(UU^\top)^2_{j_{c-1},i_c}C_{j_0} \\
+ & \sum_{i_1,\cdots i_k,j_0,\cdots j_{k-1},i_{k-1}=j_{k-1}} 1\cdot (UU^\top)^2_{j_{k-1},i_k}\cdot \prod_{c=1}^{k-2}\langle S_{i_c},S_{j_c}\rangle^2 \prod_{c=1}^{k-1}(UU^\top)^2_{j_{c-1},i_c}C_{j_0},
\end{aligned}
$$

where the first equality follows from the property just mentioned, and the inequality follows by including back the tuples of indices for which $i_{k-1} = j_{k-1}$, using that each summand is non-negative.

Our next step will be to bound the term $(UU^\top)^2_{j_{k-1},i_k}$. We have, $\|Z\|_F^2$ is

$$\begin{aligned}
&\leq \sum_{i_k,j_{k-1}} (UU^\top)^2_{i_k,j_{k-1}} \sum_{\substack{i_1,\cdots,i_{k-1}\\ j_0,\cdots,j_{k-2}}} O((\log n)/r) \\
&\cdot \prod_{c=1}^{k-2} \langle S_{i_c}, S_{j_c}\rangle^2 \prod_{c=1}^{k-1} (UU^\top)^2_{j_{c-1},i_c} C_{j_0} \\
&+ \sum_{\substack{i_1,\cdots,i_k\\ j_0,\cdots,j_{k-1}\\ i_{k-1}=j_{k-1}}} 1 \cdot (UU^\top)^2_{j_{k-1},i_k} \prod_{c=1}^{k-2} \langle S_{i_c}, S_{j_c}\rangle^2 \prod_{c=1}^{k-1} (UU^\top)^2_{j_{c-1},i_c} C_{j_0} \\
&= \underbrace{O(d(\log n)/r) \sum_{\substack{i_1,\cdots,i_{k-1}\\ j_0,\cdots,j_{k-2}}} \prod_{c=1}^{k-2} \langle S_{i_c}, S_{j_c}\rangle^2 \prod_{c=1}^{k-1} (UU^\top)^2_{j_{c-1},i_c} C_{j_0}}_{A} \\
&+ \underbrace{\sum_{\substack{i_1,\cdots,i_k\\ j_0,\cdots,j_{k-1}\\ i_{k-1}=j_{k-1}}} 1 \cdot (UU^\top)^2_{j_{k-1},i_k} \prod_{c=1}^{k-2} \langle S_{i_c}, S_{j_c}\rangle^2 \prod_{c=1}^{k-1} (UU^\top)^2_{j_{c-1},i_c} C_{j_0}}_{B},
\end{aligned}$$

where the equality uses that $\sum_{i_k,j_{k-1}} (UU^\top)^2_{i_k,j_{k-1}} = \|UU^\top\|_F^2 = d$. We first upper bound

term B:

$$
\begin{aligned}
&= \sum_{\substack{i_1,\cdots,i_k \\ j_0,\cdots,j_{k-1} \\ i_{k-1}=j_{k-1}}} 1 \cdot (UU^\top)^2_{j_{k-1},i_k} \prod_{c=1}^{k-2} \langle S_{i_c}, S_{j_c} \rangle^2 \prod_{c=1}^{k-1} (UU^\top)^2_{j_{c-1},i_c} C_{j_0} \\
&= \sum_{\substack{i_1,\cdots,i_{k-1} \\ j_0,j_1,\cdots,j_{k-1} \\ i_{k-1}=j_{k-1}}} C_{j_0} \prod_{c=1}^{k-2} \langle S_{i_c}, S_{j_c} \rangle^2 \prod_{c=1}^{k-1} (UU^\top)^2_{j_{c-1},i_c} \sum_{i_k} (UU^\top)^2_{j_{k-1},i_k} \\
&= \sum_{\substack{i_1,\cdots,i_{k-1} \\ j_0,j_1,\cdots,j_{k-1} \\ i_{k-1}=j_{k-1}}} C_{j_0} \prod_{c=1}^{k-2} \langle S_{i_c}, S_{j_c} \rangle^2 \prod_{c=1}^{k-1} (UU^\top)^2_{j_{c-1},i_c} |e_{j_{k-1}} UU^\top|^2 \\
&\leq \sum_{\substack{i_1,\cdots,i_{k-1} \\ j_0,j_1,\cdots,j_{k-1} \\ i_{k-1}=j_{k-1}}} C_{j_0} \prod_{c=1}^{k-2} \langle S_{i_c}, S_{j_c} \rangle^2 \prod_{c=1}^{k-1} (UU^\top)^2_{j_{c-1},i_c} 1 \\
&= \sum_{\substack{i_1,\cdots,i_{k-1} \\ j_0,j_1,\cdots,j_{k-2}}} C_{j_0} \prod_{c=1}^{k-2} \langle S_{i_c}, S_{j_c} \rangle^2 \prod_{c=1}^{k-1} (UU^\top)^2_{j_{c-1},i_c},
\end{aligned}
$$

where the first equality is the definition of B, the second equality follows by separating out the index i_k, the third equality uses that $\sum_{i_k} (UU^\top)^2_{j_{k-1},i_k} = \|e_{j_{k-1}} UU^\top\|_2^2$, that is, the squared norm of the j_{k-1}-th row of $UU^\top$, the inequality follows since all rows of a projection matrix $UU^\top$ have norm at most 1, and the final equality uses that j_{k-1} no longer appears in the expression.

We now merge our bounds for the terms A and B in the following way:

$$\begin{aligned}
& \|Z\|_F^2 \\
\leq\ & A + B \\
\leq\ & O(d(\log n)/r) \sum_{\substack{i_1,\cdots,i_{k-1} \\ j_0,\cdots,j_{k-2}}} \prod_{c=1}^{k-2} \langle S_{i_c}, S_{j_c} \rangle^2 \prod_{c=1}^{k-1} (UU^\top)^2_{j_{c-1},i_c} C_{j_0} \\
+\ & \sum_{\substack{i_1,\cdots,i_{k-1} \\ j_0,j_1,\cdots,j_{k-2}}} C_{j_0} \prod_{c=1}^{k-2} \langle S_{i_c}, S_{j_c} \rangle^2 \prod_{c=1}^{k-1} (UU^\top)^2_{j_{c-1},i_c} \\
=\ & (O(d(\log n)/r) + 1) \sum_{\substack{i_1,\cdots,i_{k-1} \\ j_0,\cdots,j_{k-2}}} \prod_{c=1}^{k-2} \langle S_{i_c}, S_{j_c} \rangle^2 \prod_{c=1}^{k-1} (UU^\top)^2_{j_{c-1},i_c} C_{j_0} \\
\leq\ & \cdots \\
\leq\ & (O(d(\log n)/r) + 1)^2 \sum_{\substack{i_1,\cdots,i_{k-2} \\ j_0,\cdots,j_{k-3}}} \prod_{c=1}^{k-3} \langle S_{i_c}, S_{j_c} \rangle^2 \prod_{c=1}^{k-2} (UU^\top)^2_{j_{c-1},i_c} C_{j_0} \\
\leq\ & \cdots \\
\leq\ & (O(d(\log n)/r) + 1)^{k-1} \sum_{i_1,j_0} \prod_{c=1}^{1} (UU^\top)^2_{j_{c-1},i_c} C_{j_0} \\
\leq\ & (O(d(\log n)/r) + 1)^{k-1} \left(d\|b\|_2^2 (\log^2 n)/r^2 + \|b\|_2^2 (\log n)/r\right),
\end{aligned}$$

where the first two inequalities and first equality are by definition of A and B above. The first inequality follows by induction, since at this point we have replaced k with $k-1$, and can repeat the argument, incurring another multiplicative factor of $O(d(\log n)/r) + 1$. Repeating the induction in this way we arrive at the last inequality. Finally, the last

inequality follows by plugging in the definition of C_{j_0}, using that $\sum_{i_1,j_0}(UU^\top)^2_{j_0,i_1} = d$, and

$$\sum_{j_0,i_1}(UU^\top)^2_{j_0,i_1}a^2_{j_0} = \sum_{j_0} a^2_{j_0}\sum_{i_1}(UU^\top)^2_{j_0,i_1} = \sum_{j_0} a^2_{j_0}\|e_{j_0}UU^\top\|_2^2 \leq 1,$$

where the inequality follows since each row of $UU^\top$ has norm at most 1, and a is a unit vector. The final result is that

$$\|Z\|_F^2 \leq (O(d(\log n)/r) + 1)^{k-1}\,(d\|b\|_2^2(\log^2 n)/r^2 + \|b\|_2^2(\log n)/r).$$

Chapter 25

Symmetric Norm Regression

We provide efficient algorithms for overconstrained linear regression problems with size $n \times d$ when the loss function is a symmetric norm (a norm invariant under sign-flips and coordinate-permutations). An important class of symmetric norms are Orlicz norms, where for a function G and a vector $y \in \mathbb{R}^n$, the corresponding Orlicz norm $\|y\|_G$ is defined as the unique value α such that $\sum_{i=1}^n G(|y_i|/\alpha) = 1$. When the loss function is an Orlicz norm, our algorithm produces a $(1+\epsilon)$-approximate solution for an arbitrarily small constant $\epsilon > 0$ in input-sparsity time, improving over the previously best-known algorithm which produces a $d \cdot \operatorname{polylog} n$-approximate solution. When the loss function is a general symmetric norm, our algorithm produces a $\sqrt{d} \cdot \operatorname{polylog} n \cdot \operatorname{mmc}(\ell)$-approximate solution in input-sparsity time, where $\operatorname{mmc}(\ell)$ is a quantity related to the symmetric norm under consideration. To the best of our knowledge, this is the first input-sparsity time algorithm with provable guarantees for the general class of symmetric norm regression problem. Our results shed light on resolving the universal sketching problem for linear regression, and the techniques might be of independent interest to numerical linear algebra problems more broadly.

This part is based upon the following previous publication

  Efficient Symmetric Norm Regression via Linear Sketching.

Manuscript 2019 [SWY+19]

25.1 Introduction

Linear regression is a fundamental problem in machine learning. For a data matrix $A \in \mathbb{R}^{n \times d}$ and a response vector $b \in \mathbb{R}^n$ with $n \gg d$, the overconstrained linear regression problem can be formulated as solving the following optimization problem:

$$\min_{x \in \mathbb{R}^d} \mathcal{L}(Ax - b), \tag{25.1}$$

where $\mathcal{L} : \mathbb{R}^n \to \mathbb{R}$ is a loss function. Via the technique of linear sketching, we have witnessed many remarkable speedups for linear regression for a wide range of loss functions. Such technique involves designing a sketching matrix $S \in \mathbb{R}^{r \times n}$, and showing that by solving a linear regression instance on the data matrix SA and the response vector Sb, which is usually much smaller in size, one can obtain an approximate solution to the original linear regression instance in (25.1). Sarlós showed in [Sar06] that by taking S as a Fast Johnson-Lindenstrauss Transform matrix [AC06], one can obtain $(1+\epsilon)$-approximate solutions to the least square regression problem ($\mathcal{L}(y) = \|y\|_2^2$) in $O(nd \log n + \mathrm{poly}(d/\epsilon))$ time. The running time was later improved to $O(\mathrm{nnz}(A) + \mathrm{poly}(d/\epsilon))$ [CW13, MM13, NN13a, LMP13, Coh16a]. Here $\mathrm{nnz}(A)$ is the number of non-zero entries in the data matrix A, which could be much smaller than nd for sparse data matrices. This technique was later generalized to other loss functions. By now, we have $\widetilde{O}(\mathrm{nnz}(A) + \mathrm{poly}(d/\epsilon))$[1] time algorithms for ℓ_p norms ($\mathcal{L}(y) = \|y\|_p^p$) [DDH+09, MM13, WZ13, CP15, WW19], the quantile loss function [YMM13], and M-estimators [CW15b, CW15a].

Despite we have successfully applied the technique of linear sketching to many different loss functions, ideally, it would be more desirable to design algorithms that work

[1] Throughout the paper, we use $\widetilde{O}(f)$ to denote $f \,\mathrm{polylog}\, f$.

Table 25.1: M-estimators

HUBER	$\begin{cases} x^2/2 & \lvert x\rvert \le c \\ c(\lvert x\rvert - c/2) & \lvert x\rvert > c \end{cases}$
$\ell_1 - \ell_2$	$2(\sqrt{1 + x^2/2} - 1)$
"FAIR"	$c^2 \left(\lvert x\rvert/c - \log(1 + \lvert x\rvert/c)\right)$

for a wide range of loss functions, instead of designing a new sketching algorithm for every specific loss function. Naturally, this leads to the following problem, which is the linear regression version of the universal sketching problem[2] studied in streaming algorithms [BO10, BCWY16]. We note that similar problems are also asked and studied for various algorithmic tasks, including principal component analysis [SWZ18], sparse recovery [NSW19b], approximate nearest neighbor search [ANN+17, ANN+18] and mean estimation with statistical queries [FGV17, LNRW19].

Question 25.1.1. *Is that possible to design sketching algorithms for linear regression, that work for a wide range of loss functions?*

Prior to our work, [CW15b, CW15a] studied this problem in terms of M-estimators, where the loss function employs the form $\mathcal{L}(y) = \sum_{i=1}^{n} G(y_i)$ for some function G. See Table 25.1 for a list a M-estimators. However, much less is known for the case where the loss function $\mathcal{L}(\cdot)$ is a norm, except for ℓ_p norms. Recently, Andoni et al. [ALS+18] tackle Problem 25.1.1 for Orlicz norms, which can be seen as a scale-invariant version of M-estimators. For a function G and a vector $y \in \mathbb{R}^n$ with $y \neq 0$, the corresponding *Orlicz*

[2] https://sublinear.info/index.php?title=Open_Problems:30.

norm $\|y\|_G$ is defined as the unique value α such that

$$\sum_{i=1}^{n} G(|y_i|/\alpha) = 1. \tag{25.2}$$

When $y = 0$, we define $\|y\|_G$ to be 0. Note that Orlicz norms include ℓ_p norms as special cases, by taking $G(z) = |z|^p$ for some $p \geq 1$. Under certain assumptions on the function G, [ALS+18] obtains the first input-sparsity time algorithm for solving Orlicz norm regression. More precisely, in $\widetilde{O}(\mathrm{nnz}(A) + \mathrm{poly}(d \log n))$ time, their algorithm obtains a solution $\widehat{x} \in \mathbb{R}^d$ such that $\|A\widehat{x} - b\|_G \leq d \cdot \mathrm{polylog}\, n \cdot \min_{x \in \mathbb{R}^d} \|Ax - b\|_G$.

There are two natural problems left open by the work of [ALS+18]. First, the algorithm in [ALS+18] has approximation ratio as large as $d \cdot \mathrm{polylog}\, n$. Although this result is interesting from a theoretical point of view, such a large approximation ratio is prohibited for machine learning applications in practice. Is it possible to obtain an algorithm that runs in $\widetilde{O}(\mathrm{nnz}(A) + \mathrm{poly}(d/\epsilon))$ time, with approximation ratio $1+\epsilon$, for arbitrarily small ϵ, similar to the case of ℓ_p norms? Moreover, although Orlicz norm includes a wide range of norms, many other important norms, e.g., top-k norms (the sum of absolute values of the leading k coordinates of a vector), max-mix of ℓ_p norms (e.g. $\max\{\|x\|_2, c\|x\|_1\}$ for some $c > 0$), and sum-mix of ℓ_p norms (e.g. $\|x\|_2 + c\|x\|_1$ for some $c > 0$), are not Orlicz norms. More complicated examples include the k-support norm [AFS12] and the box-norm [MPS14], which have found applications in sparse recovery. In light of Problem 25.1.1, it is natural to ask whether it is possible to apply the technique of linear sketching to a broader class of norms. In this paper, we obtain affirmative answers to both problems, and make progress towards finally resolving Problem 25.1.1.

Notations. For a matrix $A \in \mathbb{R}^{n \times d}$, we use $A_i \in \mathbb{R}^d$ to denote its i-th row, viewed as a column vector. For n real numbers $x_1, x_2, \cdots, x_n$, we define $\mathrm{diag}(x_1, x_2, \cdots, x_n) \in \mathbb{R}^{n \times n}$ to be the diagonal matrix where the i-th diagonal entry is x_i. For a vector $x \in \mathbb{R}^n$ and $p \geq 1$, we use $\|x\|_p$ to denote its ℓ_p norm, and $\|x\|_0$ to denote its ℓ_0 norm, i.e., the number of non-zero entries in x. For two vectors $x, y \in \mathbb{R}^n$, we use $\langle x, y \rangle$ to denote their inner product. For any $n \in \mathbb{N}_+$, we use $[n]$ to denote the set $\{1, 2, \cdots, n\}$. For $0 \leq p \leq 1$, we define $\mathrm{Ber}(p)$ to be the Bernoulli distribution with parameter p. We use $\mathbb{S}^{n-1}$ to denote the unit ℓ_2 sphere in $\mathbb{R}^n$, i.e., $\mathbb{S}^{n-1} = \{x \in \mathbb{R}^n \mid \|x\|_2 = 1\}$. We use $\mathbb{R}_{\geq 0}$ to denote the set of all non-negative real numbers, i.e., $\mathbb{R}_{\geq 0} = \{x \in \mathbb{R} \mid x \geq 0\}$.

25.1.1 Our Contributions

Algorithm for Orlicz Norms. Our first contribution is a unified algorithm which produces $(1+\epsilon)$-approximate solutions to the linear regression problem in (25.1), when the loss function $\mathcal{L}(\cdot)$ is an Orlicz norm. Before introducing our results, we first give our assumptions on the function G appeared in (25.2).

Assumption 25.1.2. *We assume the function $G : \mathbb{R} \to \mathbb{R}_{\geq 0}$ satisfies the following properties:*

1. *G is a strictly increasing convex function on $[0, \infty)$;*
2. *$G(0) = 0$, and for all $x \in \mathbb{R}$, $G(x) = G(-x)$;*
3. *There exists some $C_G > 0$, such that for all $0 < x < y$, $G(y)/G(x) \leq C_G (y/x)^2$.*

The first two conditions in Assumption 25.1.2 are necessary to make sure the corresponding Orlicz norm $\|\cdot\|_G$ is indeed a norm, and the third condition requires the function G

to have at most quadratic growth, which can be satisfied by all M-estimators in Table 25.1 and is also required by prior work [ALS+18]. Notice that our assumptions are weaker than those in [ALS+18]. In [ALS+18], it is further required that $G(x)$ is a linear function when $x > 1$, and G is twice differentiable on an interval $(0, \delta_G)$ for some $\delta_G > 0$. Given our assumptions on G, our main theorem is summarized as follow.

Theorem 25.1.3. *For a function G that satisfies Assumption 25.1.2, there exists an algorithm that, on any input $A \in \mathbb{R}^{n\times d}$ and $b \in \mathbb{R}^n$, finds a vector x^* in time $\widetilde{O}(\mathrm{nnz}(A) + \mathrm{poly}(d/\epsilon))$, such that with probability at least 0.9, $\|Ax^* - b\|_G \leq (1+\epsilon)\min_{x\in\mathbb{R}^d}\|Ax - b\|_G$.*

To the best of our knowledge, this is the first input-sparsity time algorithm with $(1+\epsilon)$-approximation guarantee, that goes beyond ℓ_p norms, the quantile loss function, and M-estimators. See Table 25.2 for a more comprehensive comparison with previous results.

Algorithm for Symmetric Norms. We further study the case when the loss function $\mathcal{L}(\cdot)$ is a symmetric norm. Symmetric norm is a more general class of norms, which includes all norms that are invariant under sign-flips and coordinate-permutations. Formally, we define symmetric norms as follow.

Definition 25.1.1. A norm $\|\cdot\|_\ell$ is called a *symmetric norm*, if

$$\|(y_1, y_2, \ldots, y_n)\|_\ell = \|(s_1 y_{\sigma_1}, s_2 y_{\sigma_2}, \ldots, s_n y_{\sigma_n})\|_\ell$$

for any permutation σ and any assignment of $s_i \in \{-1, 1\}$.

Symmetric norm includes ℓ_p norms and Orlicz norms as special cases. It also includes all examples provided in the introduction, i.e., top-k norms, max-mix of ℓ_p norms,

Table 25.2: Comparison between input-sparsity time linear regression algorithms

Reference	Loss Function	Approximation Ratio
[DDH+09, MM13, WZ13, CP15, WW19]	ℓ_p norms	$1+\epsilon$
[YMM13]	Quantile loss function	$1+\epsilon$
[CW15b, CW15a]	M-estimators	$1+\epsilon$
[ALS+18]	Orlicz norms	$d \cdot \operatorname{polylog} n$
Theorem 25.1.3	Orlicz norms	$1+\epsilon$
Theorem 25.1.4	Symmetric norms	$\sqrt{d} \cdot \operatorname{polylog} n \cdot \operatorname{mmc}(\ell)$

sum-mix of ℓ_p norms, the k-support norm [AFS12] and the box-norm [MPS14], as special cases. Understanding this general set of loss functions can be seen as a preliminary step to resolve Problem 25.1.1. Our main result for symmetric norm regression is summarized in the following theorem.

Theorem 25.1.4. *Given a symmetric norm $\|\cdot\|_\ell$, there exists an algorithm that, on any input $A \in \mathbb{R}^{n\times d}$ and $b \in \mathbb{R}^n$, finds a vector x^* in time $\widetilde{O}(\operatorname{nnz}(A) + \operatorname{poly}(d))$, such that with probability at least 0.9, $\|Ax^* - b\|_\ell \leq \sqrt{d} \cdot \operatorname{polylog} n \cdot \operatorname{mmc}(\ell) \cdot \min_{x\in\mathbb{R}^d} \|Ax - b\|_\ell$.*

In the above theorem, $\operatorname{mmc}(\ell)$ is a characteristic of the symmetric norm $\|\cdot\|_\ell$, which has been proven to be essential in streaming algorithms for symmetric norms [BBC+17]. See Definition 25.3.3 for the formal definition of $\operatorname{mmc}(\ell)$, and Section 25.3 for more details about $\operatorname{mmc}(\ell)$. In particular, for ℓ_p norms with $p \leq 2$, top-k norms with $k \geq n/\operatorname{polylog} n$, max-mix of ℓ_2 norm and ℓ_1 norm ($\max\{\|x\|_2, c\|x\|_1\}$ for some $c > 0$), sum-mix of ℓ_2 norm and ℓ_1 norm ($\|x\|_2 + c\|x\|_1$ for some $c > 0$), the k-support norm, and the box-norm, $\operatorname{mmc}(\ell)$ can all be upper bounded by $\operatorname{polylog} n$, which implies our algorithm has approximation ratio $\sqrt{d} \cdot \operatorname{polylog} n$ for all these norms. This clearly demonstrates the generality of our algorithm.

25.1.2 Technical Overview

Similar to previous works on using linear sketching to speed up solving linear regression, our core technique is to provide efficient dimensionality reduction methods for Orlicz norms and general symmetric norms. In this section, we discuss the techniques behind our results.

Row Sampling Algorithm for Orlicz Norms. Compared to prior work on Orlicz norm regression [ALS+18] which is based on random projection[3], our new algorithm is based on row sampling. For a given matrix $A \in \mathbb{R}^{n \times d}$, our goal is to output a *sparse* weight vector $w \in \mathbb{R}^n$ with at most $\mathrm{poly}(d \log n/\epsilon)$ non-zero entries, such that with high probability, for all $x \in \mathbb{R}^d$,

$$(1-\epsilon)\|Ax-b\|_G \leq \|Ax-b\|_{G,w} \leq (1+\epsilon)\|Ax-b\|_G. \tag{25.3}$$

Here, for a weight vector $w \in \mathbb{R}^n$ and a vector $y \in \mathbb{R}^n$, the *weighted Orlicz norm* $\|y\|_{G,w}$ is defined as the unique value α such that $\sum_{i=1}^n w_i G(|y_i|/\alpha) = 1$. See Definition 25.2.1 for the formal definition of weighted Orlicz norm. To obtain a $(1+\epsilon)$-approximate solution to Orlicz norm regression, by (25.3), it suffices to solve

$$\min_{x \in \mathbb{R}^d} \|Ax-b\|_{G,w}. \tag{25.4}$$

Since the vector $w \in \mathbb{R}^n$ has at most $\mathrm{poly}(d \log n/\epsilon)$ non-zero entries, and we can ignore all rows of A with zero weights, there are at most $\mathrm{poly}(d \log n/\epsilon)$ remaining rows in A in the optimization problem in (25.4). Furthermore, as we show in Lemma 25.2.1, $\|\cdot\|_{G,w}$ is

[3]Even for ℓ_p norms with $p < 2$, embeddings based on random projections will necessarily induce a distortion factor polynomial in d, as shown in [WW19].

a seminorm, which implies we can solve the optimization problem in (25.4) in $\mathrm{poly}(d \log n/\epsilon)$ time, by simply solving a convex program with size $\mathrm{poly}(d \log n/\epsilon)$. Thus, we focus on how to obtain the weight vector $w \in \mathbb{R}^n$ in the remaining part. Furthermore, by taking $\mathbf{Ab}$ to be a matrix whose first d columns are A and last column is b, to satisfy (25.3), it suffices to find a weight vector w such that for all $x \in \mathbb{R}^{d+1}$,

$$(1-\epsilon)\|\mathbf{Ab}x\|_G \leq \|\mathbf{Ab}x\|_{G,w} \leq (1+\epsilon)\|\mathbf{Ab}x\|_G. \tag{25.5}$$

Hence, we ignore the response vector b in the remaining part of the discussion.

We obtain the weight vector w via importance sampling. We compute a set of sampling probabilities $\{p_i\}_{i=1}^n$ for each row of the data matrix A, and sample the rows of A according to these probabilities. The i-th entry of the weight vector w is then set to be $w_i = 1/p_i$ with probability p_i and $w_i = 0$ with probability $1 - p_i$. However, unlike ℓ_p norms, Orlicz norms are not "entry-wise" norms, and it is not even clear that such a sampling process gives an unbiased estimation. Our key insight here is that for a vector Ax with unit Orlicz norm, if for all $x \in \mathbb{R}^d$,

$$(1-\epsilon)\sum_{i=1}^n G((Ax)_i) \leq \sum_{i=1}^n w_i G((Ax)_i) \leq (1+\epsilon)\sum_{i=1}^n G((Ax)_i), \tag{25.6}$$

then (25.5) holds, which follows from the convexity of the function G. See Lemma 25.2.5 and its proof for more details. Therefore, it remains to develop a way to define and calculate $\{p_i\}_{i=1}^n$, such that the total number of sampled rows is small.

Our method for defining and computing sampling probabilities p_i is inspired by row sampling algorithms for ℓ_p norms [DDH+09]. Here, the key is to obtain an upper bound on the contribution of each entry to the summation $\sum_{i=1}^n G((Ax)_i)$. Indeed, suppose for some

vector $u \in \mathbb{R}^n$ such that $G(Ax)_i \le u_i$ for all $x \in \mathbb{R}^d$ with $\|Ax\|_G = 1$, we can then sample each row of A with sampling probability proportional to u_i. Now, by standard concentration inequalities and a net argument, (25.6) holds with high probability. It remains to upper bound the total number of sampled rows, which is proportional to $\sum_{i=1}^n u_i$.

We use the case of ℓ_2 norm, i.e., $G(x) = x^2$, as an example to illustrate our main ideas for choosing the vector $u \in \mathbb{R}^n$. Suppose $U \in \mathbb{R}^{n \times d}$ is an orthonormal basis matrix of the column space of A, then the *leverage score*[4] is defined to be the squared ℓ_2 norm of each row of U. Indeed, leverage score gives an upper bound on the contribution of each row to $\|Ux\|_2^2$, since by Cauchy-Schwarz inequality, for each row U_i of U, we have $\langle U_i, x\rangle^2 \le \|U_i\|_2^2\|x\|_2^2 = \|U_i\|_2^2\|Ux\|_2^2$, and thus we can set $u_i = \|U_i\|_2^2$. It is also clear that $\sum_{i=1}^n u_i = d$.

For general Orlicz norms, leverage scores are no longer upper bounds on $G((Ux)_i)$. Inspired by the role of orthonormal bases in the case of ℓ_2 norm, we first define well-conditioned basis for general Orlicz norms as follow.

Definition 25.1.2. Let $\|\cdot\|_G$ be an Orlicz norm induced by a function G which satisfies Assumption 25.1.2. We say $U \in \mathbb{R}^{n \times d}$ is a well-conditioned basis with condition number $\kappa_G = \kappa_G(U)$ if for all $x \in \mathbb{R}^d$, $\|x\|_2 \le \|Ux\|_G \le \kappa_G\|x\|_2$.

Given this definition, when $\|Ux\|_G = 1$, by Cauchy-Schwarz inequality and monotonicity of G, we can show that $G((Ux)_i) \le G(\|U_i\|_2\|x\|_2) \le G(\|U_i\|_2\|Ux\|_G) \le G(\|U_i\|_2)$. This also leads to our definition of Orlicz norm leverage scores.

[4] See, e.g., [Mah11a], for a survey on leverage scores.

Definition 25.1.3. Let $\|\cdot\|_G$ be an Orlicz norm induced by a function G which satisfies Assumption 25.1.2. For a given matrix $A \in \mathbb{R}^{n\times d}$ and a well-conditioned basis U of the column space of A, the *Orlicz norm leverage score* of the i-th row of A is defined to be $G(\|U_i\|_2)$.

It remains to give an upper bound on the summation of Orlicz norm leverage scores of all rows. Unlike the ℓ_2 norm, it is not immediately clear how to use the definition of well-conditioned basis to obtain such an upper bound for general Orlicz norms. To achieve this goal, we use a novel probabilistic argument. Suppose one takes x to be a vector with i.i.d. Gaussian random variables. Then each entry of Ux has the same distribution as $\|U_i\|_2 \cdot g_i$, where $\{g_i\}_{i=1}^n$ is a set of standard Gaussian random variables. Thus, with constant probability, $\sum_{i=1}^n G((Ux)_i)$ is an upper bound on the summation of Orlicz norm leverage scores. Furthermore, by the growth condition of the function G, we have $\sum_{i=1}^n G((Ux)_i) \leq C_G\|Ux\|_G^2$. Now by Definition 25.1.2, $\|Ux\|_G \leq \kappa_G\|x\|_2$, and $\|x\|_2 \leq O(\sqrt{d})$ with constant probability by tail inequalities of Gaussian random variables. This implies an upper bound on the summation of Orlicz norm leverage scores. See Lemma 25.2.2 and its proof for more details.

Our approach for constructing well-conditioned bases is inspired by [SW11]. In Lemma 25.2.3, we show that given a subspace embedding Π which embeds the column space of A with Orlicz norm $\|\cdot\|_G$ into the ℓ_2 space with distortion κ, then one can construct a well-conditioned basis with condition number $\kappa_G \leq \kappa$. The running time is dominated by calculating ΠA and doing a QR-decomposition on ΠA. To this end, we can use the oblivi-

ous subspace embedding for Orlicz norms in Corollary 25.3.4[5] to construct well-conditioned bases. The embedding in Corollary 25.3.4 has $O(d)$ rows and $\kappa = \text{poly}(d \log n)$, and calculating ΠA can be done in $\widetilde{O}(\text{nnz}(A) + \text{poly}(d))$ time. Using such an embedding to construct the well-conditioned basis, our row sampling algorithm produces a vector w that satisfies (25.6) with $\|w\|_0 \leq \text{poly}(d \log n/\epsilon)$ in time $\widetilde{O}(\text{nnz}(A) + \text{poly}(d))$.

Oblivious Subspace Embeddings for Symmetric Norms. To obtain a faster algorithm for linear regression when the loss function is a general symmetric norm, we show that there exists a distribution over embedding matrices, such that if S is a random matrix drawn from that distribution, then for any $n \times d$ matrix A, with constant probability, for all $x \in \mathbb{R}^d$, $\|Ax\|_\ell \leq \|SAx\|_2 \leq \text{poly}(d \log n) \cdot \text{mmc}(\ell) \cdot \|Ax\|_\ell$. Moreover, the embedding matrix S is *sparse*, and calculating SA requires only $\widetilde{O}(\text{nnz}(A) + \text{poly}(d))$ time. Another favorable property of S is that it is an *oblivious subspace embeeding*, meaning the distribution of S does not depend on A. To achieve this goal, it is sufficient to construct a random diagonal matrix D such that for any fixed vector $x \in \mathbb{R}^n$,

$$\Pr[\|Dx\|_2 \geq \Omega(1/\text{poly}(d \log n)) \cdot \|x\|_\ell] \geq 1 - \exp(-\Omega(d \log n)), \tag{25.7}$$

and

$$\Pr[\|Dx\|_2 \leq \text{poly}(d \log n) \cdot \text{mmc}(\ell) \cdot \|x\|_\ell] \geq 1 - O(1/d). \tag{25.8}$$

Our construction is inspired by the sub-sampling technique in [IW05], which was used for sketching symmetric norms in data streams [BBC+17]. Throughout the discussion, we

[5] Alternatively, we can use the oblivious subspace embedding in [ALS+18] for this step. However, as we have discussed, the oblivious subspace embedding in [ALS+18] requires stronger assumptions on the function $G : \mathbb{R} \to \mathbb{R}_{\geq 0}$ than those in Assumption 25.1.2, which restricts the class of Orlicz norms to which our algorithm can be applied.

use $\xi^{(q)} \in \mathbb{R}^n$ to denote a vector with q non-zero entries and each entry is $1/\sqrt{q}$. Let us start with a special case where the vector $x \in \mathbb{R}^n$ has s non-zero entries and each non-zero entry is 1. It is easy to see $\|x\|_\ell = \sqrt{s}\|\xi^{(s)}\|_\ell$. Now consider a random diagonal matrix D which corresponds to a sampling process, i.e., each diagonal entry is set to be 1 with probability p and 0 with probability $1-p$. Our goal is to show that $\sqrt{1/p}\|\xi^{(1/p)}\|_\ell \cdot \|Dx\|_2$ is a good estimator of $\|x\|_\ell$. If $p = \Theta(d \log n/s)$, then with probability at least $1 - \exp(-\Omega(d \log n))$, Dx will contain at least one non-zero entry from x, in which case (25.7) is satisfied. However, we do not know s in advance. Thus, we use $t = O(\log n)$ different matrices $D_1, D_2, \cdots, D_t$, where D_i has sampling probability $1/2^i$. Clearly at least one such D_j can establish (25.7). For the upper bound part, if p is much smaller than $1/s$, then Dx will never contain a non-zero entry from x. Otherwise, in expectation Dx will contain ps non-zero entries, in which case our estimation will be roughly $\sqrt{s}\|\xi^{(1/p)}\|_\ell$, which can be upper bounded by $O(\log n \cdot \mathrm{mmc}(\ell) \cdot \sqrt{s}\|\xi^{(s)}\|_\ell)$. At this point, (25.8) follows from Markov's inequality. See Section 25.7.5 for the formal argument, and Section 25.3 for a detailed discussion on $\mathrm{mmc}(\ell)$.

To generalize the above argument to general vectors, for a vector $x \in \mathbb{R}^n$, we conceptually partition its entries into $\Theta(\log n)$ groups, where the i-th group contains entries with magnitude in $[2^i, 2^{i+1})$. By averaging, at least one group of entries contributes at least $\Omega(1/\log n)$ fraction to the value of $\|x\|_\ell$. To establish (25.7), we apply the lower bound part of the argument in the previous paragraph to this "contributing" group. To establish (25.8), we apply the upper bound part of the argument to all groups, which will only induce an additional $O(\log n)$ factor in the approximation ratio, by triangle inequality.

Since our oblivious subspace embedding embeds a given symmetric norm into the ℓ_2 space, in order to obtain an approximate solution to symmetric norm regression, we only need

to solve a least square regression instance with much smaller size. This is another advantage of our subspace embedding, since the least square regression problem is a well-studied problem in optimization and numerical linear algebra, for which many efficient algorithms are known, both in theory and in practice.

25.2 Linear Regression for Orlicz Norms

In this section, we introduce our results for Orlicz norm regression.

Weighted Orlicz Norm. We first give the definition of weighted Orlicz norm.

Definition 25.2.1. For a function G that satisfies Assumption 25.1.2 and a weight vector $w \in \mathbb{R}^n$ such that $w_i \geq 0$ for all $i \in [n]$, for a vector $x \in \mathbb{R}^n$, if $\sum_{i=1}^n w_i \cdot |x_i| = 0$, then the weighted Orlicz norm $\|x\|_{G,w}$ is defined to be 0. Otherwise, the weighted Orlicz norm $\|x\|_{G,w}$ is defined as the unique value $\alpha > 0$ such that $\sum_{i=1}^n w_i G(|x_i|/\alpha) = 1$.

When $w_i = 1$ for all $i \in [n]$, we have $\|x\|_{G,w} = \|x\|_G$ where $\|x\|_G$ is the (unweighted) Orlicz norm. It is well known that $\|\cdot\|_G$ is a norm. We show in the following lemma that $\|\cdot\|_{G,w}$ is a seminorm.

Lemma 25.2.1. *For a function G that satisfies Assumption 25.1.2 and a weight vector $w \in \mathbb{R}^n$ such that $w_i \geq 0$ for all $i \in [n]$, for all $x, y \in \mathbb{R}^n$, we have (i) $\|x\|_{G,w} \geq 0$, (ii) $\|x+y\|_{G,w} \leq \|x\|_{G,w} + \|y\|_{G,w}$, and (iii) $\|ax\|_{G,w} = |a| \cdot \|x\|_{G,w}$ for all $a \in \mathbb{R}$.*

Leverage Scores and Well-Conditioned Bases for Orlicz Norms. The following lemma establishes an upper bound on the summation of Orlicz norm leverage scores defined in Definition 25.1.3.

Lemma 25.2.2. *Let $\|\cdot\|_G$ be an Orlicz norm induced by a function G which satisfies Assumption 25.1.2. Let $U \in \mathbb{R}^{n \times d}$ be a well-conditioned basis with condition number κ_G as in Definition 25.1.2. Then we have $\sum_{i=1}^n G(\|U_i\|_2) \leq O(C_G d \kappa_G^2)$,*

Now we show that given a subspace embedding which embeds the column space of A with Orlicz norm $\|\cdot\|_G$ into the ℓ_2 space with distortion κ, then one can construct a well-conditioned basis with condition number $\kappa_G \leq \kappa$.

Lemma 25.2.3. *Let $\|\cdot\|_G$ be an Orlicz norm induced by a function G which satisfies Assumption 25.1.2. For a given matrix $A \in \mathbb{R}^{n\times d}$ and an embedding matrix $\Pi \in \mathbb{R}^{s\times n}$, suppose for all $x \in \mathbb{R}^d$, $\|Ax\|_G \leq \|\Pi Ax\|_2 \leq \kappa\|Ax\|_G$. Let $Q \cdot R = \frac{1}{\kappa}\Pi A$ be a QR-decomposition of $\frac{1}{\kappa}\Pi A$. Then AR^{-1} is a well-conditioned basis (see Definition 25.1.2) with $\kappa_G(AR^{-1}) \leq \kappa$.*

The following lemma shows how to estimate Orlicz norm leverage scores given a change of basis matrix $R \in \mathbb{R}^{d\times d}$, in $\widetilde{O}(\mathrm{nnz}(A) + \mathrm{poly}(d))$ time.

Lemma 25.2.4. *Let $\|\cdot\|_G$ be an Orlicz norm induced by a function G which satisfies Assumption 25.1.2. For a given matrix $A \in \mathbb{R}^{n\times d}$ and $R \in \mathbb{R}^{d\times d}$, there exists an algorithm that outputs $\{u_i\}_{i=1}^n$ such that with probability at least 0.99, $u_i = \Theta(G(\|(AR^{-1})_i\|_2))$ for all $1 \leq i \leq n$. The algorithm runs in $\widetilde{O}(\mathrm{nnz}(A) + \mathrm{poly}(d))$ time.*

The Row Sampling Algorithm. Based on the notion of Orlicz norm leverage scores and well-conditioned bases, we design a row sampling algorithm for Orlicz norms.

Lemma 25.2.5. *Let $\|\cdot\|_G$ be an Orlicz norm induced by a function G which satisfies Assumption 25.1.2. Let $U \in \mathbb{R}^{n\times d}$ be a well-conditioned basis with condition number $\kappa_G = \kappa_G(U)$ as in Definition 25.1.2. For sufficiently small ϵ and δ, and sufficiently large constant C, let $\{p_i\}_{i=1}^n$ be a set of sampling probabilities satisfying $p_i \geq \min\left\{1, C\left(\log(1/\delta) + d\log(1/\epsilon)\right)\epsilon^{-2}G\left(\|U_i\|_2\right)\right\}$. Let w be a vector whose i-th entry is set to be $w_i = 1/p_i$ with probability p_i and $w_i = 0$ with*

probability $1-p_i$*, then with probability at least* $1-\delta$*, for all* $x \in \mathbb{R}^d$*, we have* $(1-\epsilon)\|Ux\|_G \leq \|Ux\|_{G,w} \leq (1+\epsilon)\|Ux\|_G$.

Solving Linear Regression for Orlicz Norms. Now we combine all ingredients to give an algorithm for Orlicz norm regression. We use $\mathbf{Ab} \in \mathbb{R}^{n\times(d+1)}$ to denote a matrix whose first d columns are A and the last column is b. The algorithm is described in Figure 25.1, and we prove its running time and correctness in Theorem 25.2.6. We assume we are given an embedding matrix Π, such that for all $x \in \mathbb{R}^{d+1}$, $\|\mathbf{Ab}x\|_G \leq \|\Pi\mathbf{Ab}x\|_2 \leq \kappa\|\mathbf{Ab}x\|_G$. The construction of Π and the value κ will be given in Corollary 25.3.4. In Appendix 25.8.1, we use Theorem 25.2.6 and Corollary 25.3.4 to formally prove Theorem 25.1.3.

1. For the given embedding matrix Π, calculate $\Pi\mathbf{Ab}$ and invoke QR-decomposition on $\Pi\mathbf{Ab}/\kappa$ to obtain $Q \cdot R = \Pi\mathbf{Ab}/\kappa$.
2. Invoke Lemma 25.2.4 to obtain $\{u_i\}_{i=1}^n$ such that $u_i = \Theta(G(\|(\mathbf{Ab}R^{-1})_i\|_2))$.
3. For a sufficiently large constant C, let $\{p_i\}_{i=1}^n$ be a set of sampling probabilities with $p_i \geq \min\left\{1, C\cdot d\cdot\epsilon^{-2}\log(1/\epsilon)\cdot G\left(\|(\mathbf{Ab}R^{-1})_i\|_2\right)\right\}$, and w be a vector whose i-th entry $w_i = 1/p_i$ with probability p_i and $w_i = 0$ with probability $1-p_i$.
4. Calculate $x^* = \mathrm{argmin}_{x\in\mathbb{R}^d}\|Ax-b\|_{G,w}$. Return x^*.

Figure 25.1: Algorithm for Orlicz norm regression

Theorem 25.2.6. *Let* $\|\cdot\|_G$ *be an Orlicz norm induced by a function* G *which satisfies Assumption 25.1.2. Given an embedding matrix* Π*, such that for all* $x \in \mathbb{R}^d$*,* $\|\mathbf{Ab}x\|_G \leq \|\Pi\mathbf{Ab}x\|_2 \leq \kappa\|\mathbf{Ab}x\|_G$*, with probability at least* 0.9*, the algorithm in Figure 25.1 outputs* $x^* \in \mathbb{R}^d$ *in time* $\mathrm{poly}(d\kappa/\epsilon) + \mathcal{T}_{\mathrm{QR}}(\Pi\mathbf{Ab})$*, such that* $\|Ax^*-b\|_G \leq (1+\epsilon)\min_{x\in\mathbb{R}^d}\|Ax-b\|_G$*. on $\Pi\mathbf{Ab}$.

25.3 Linear Regression for Symmetric Norms

In this section, we introduce SymSketch, a subspace embedding for symmetric norms.

Definition of SymSketch. We first formally define SymSketch. Due to space limitation, we give the definition of Gaussian embeddings, CountSketch embeddings and their compositions in Appendix 25.7.1.1.

Definition 25.3.1 (Symmetric Norm Sketch (SymSketch))**.** Let $t = \Theta(\log n)$. Let $\widetilde{D} \in \mathbb{R}^{n(t+1)\times n}$ be a matrix defined as $\widetilde{D} = \begin{bmatrix} w_0 D_0 \\ w_1 D_1 \\ \vdots \\ w_t D_t \end{bmatrix}$, where for each $i \in \{0, 1, \ldots, t\}$, $D_i = \mathrm{diag}(z_{i,1}, z_{i,2}, \ldots, z_{i,n}) \in \mathbb{R}^{n\times n}$ and $z_{i,j} \sim \mathrm{Ber}(1/2^i)$ for each $j \in [n]$. Moreover, $w_i = \|(\underbrace{1, 1, \ldots, 1}_{2^i \text{ ones}}, 0, \ldots, 0)\|_\ell$. Let $\Pi \in \mathbb{R}^{O(d)\times n(t+1)}$ be a composition of Gaussian embedding and CountSketch embedding (Definition 25.7.4) with $\epsilon = 0.1$, and $S = \Pi\widetilde{D}$. We say $S \in \mathbb{R}^{O(d)\times n}$ is a SymSketch.

Modulus of Concentration. Now we give the definition of $\mathrm{mmc}(\ell)$ for a symmetric norm.

Definition 25.3.2 ([BBC+17])**.** Let $\mathcal{X}$ denote the uniform distribution over $\mathbb{S}^{n-1}$. The *median* of a symmetric norm $\|\cdot\|_\ell$ is the unique value M_ℓ such that $\Pr_{x\sim\mathcal{X}}[\|x\|_\ell \geq M_\ell] \geq 1/2$ and $\Pr_{x\sim\mathcal{X}}[\|x\|_\ell \leq M_\ell] \geq 1/2$.

Definition 25.3.3 ([BBC+17])**.** For a given symmetric norm $\|\cdot\|_\ell$, we define the *modulus of concentration* to be $\mathrm{mc}(\ell) = \max_{x\in\mathbb{S}^{n-1}} \|x\|_\ell / M_\ell$, and define the *maximum modulus of concentration* to be $\mathrm{mmc}(\ell) = \max_{k\in[n]} \mathrm{mc}(\ell^{(k)})$, where $\|\cdot\|_{\ell^{(k)}}$ is a norm on $\mathbb{R}^k$ which is defined to be $\|(x_1, x_2, \cdots, x_k)\|_{\ell^{(k)}} = \|(x_1, x_2, \cdots, x_k, 0, \cdots, 0)\|_\ell$.

It has been shown in [BBC+17] that $\mathrm{mmc}(\ell) = \Theta(n^{1/2-1/p})$ for ℓ_p norms when $p > 2$, $\mathrm{mmc}(\ell) = \Theta(1)$ for ℓ_p norms when $p \leq 2$, $\mathrm{mmc}(\ell) = \widetilde{\Theta}(\sqrt{n/k})$ for top-k norms, and $\mathrm{mmc}(\ell) = O(\log n)$ for the k-support norm [AFS12] and the box-norm [MPS14]. We show that $\mathrm{mmc}(\ell)$ is upper bounded by $O(1)$ for max-mix of ℓ_2 norm and ℓ_1 norm and sum-mix of ℓ_2 norm and ℓ_1 norm.

Lemma 25.3.1. *For a real number $c > 0$, let $\|x\|_{\ell_a} = \|x\|_2 + c\|x\|_1$ and $\|x\|_{\ell_b} = \max\{\|x\|_2, c\|x\|_1\}$. We have $\mathrm{mmc}(\ell_a) = O(1)$ and $\mathrm{mmc}(\ell_b) = O(1)$.*

Moreover, we show that for an Orlicz norm $\|\cdot\|_G$ induced by a function G which satisfies Assumption 25.1.2, $\mathrm{mmc}(\ell)$ is upper bounded by $O(\sqrt{C_G}\log n)$.

Lemma 25.3.2. *For an Orlicz norm $\|\cdot\|_G$ on $\mathbb{R}^n$ induced by a function G which satisfies Assumption 25.1.2, $\mathrm{mmc}(\ell)$ is upper bounded by $O(\sqrt{C_G}\log n)$.*

Subspace Embedding. The following theorem shows that SymSketch is a subspace embedding.

Theorem 25.3.3. *Let $S \in \mathbb{R}^{O(d)\times n}$ be a SymSketch as defined in Definition 25.3.1. For a given matrix $A \in \mathbb{R}^{n\times d}$, with probability at least 0.9, for all $x \in \mathbb{R}^d$,*

$$\Omega\left(\frac{1}{\sqrt{d}\log^3 n}\right)\cdot\|Ax\|_\ell \leq \|SAx\|_2 \leq O\left(d^2\,\mathrm{mmc}(\ell)\cdot\log^{5/2} n\right)\cdot\|Ax\|_\ell.$$

Furthermore, the running time of computing SA is $\widetilde{O}(\mathrm{nnz}(A) + \mathrm{poly}(d))$.

Combine Theorem 25.3.3 with Lemma 25.3.2, we have the following corollary.

Corollary 25.3.4. *Let $\|\cdot\|_G$ be an Orlicz norm induced by a function G which satisfies Assumption 25.1.2. Let $S \in \mathbb{R}^{O(d)\times n}$ be a* SymSketch *as defined in Definition 25.3.1. For a given matrix $A \in \mathbb{R}^{n\times d}$, with probability at least 0.9, for all $x \in \mathbb{R}^d$,*

$$\Omega\left(\frac{1}{\sqrt{d}\log^3 n}\right)\cdot\|Ax\|_\ell \le \|SAx\|_2 \le O\left(\sqrt{C_G}d^2\log^{7/2} n\right)\cdot\|Ax\|_\ell.$$

Furthermore, the running time of computing SA is $\widetilde{O}(\mathrm{nnz}(A)+\mathrm{poly}(d))$.

25.4 Conclusion

In this paper, we give efficient algorithms for solving the overconstrained linear regression problem, when the loss function is a symmetric norm. For the special case when the loss function is an Orlicz norm, our algorithm produces a $(1+\epsilon)$-approximate solution in $\widetilde{O}(\mathrm{nnz}(A) + \mathrm{poly}(d/\epsilon))$ time. When the loss function is a general symmetric norm, our algorithm produces a $\sqrt{d} \cdot \mathrm{polylog}\, n \cdot \mathrm{mmc}(\ell)$-approximate solution in $\widetilde{O}(\mathrm{nnz}(A) + \mathrm{poly}(d))$ time.

In light of Problem 25.1.1, there are a few interesting problems that remain open. Is that possible to design an algorithm that produces $(1+\epsilon)$-approximate solutions to the linear regression problem, when the loss function is a general symmetric norm? Furthermore, is that possible to use the technique of linear sketching to speed up the overconstrained linear regression problem, when the loss function is a general norm? Answering these problems could lead to a better understanding of Problem 25.1.1.

25.5 Preliminaries

Notations. For a matrix $A \in \mathbb{R}^{n\times d}$, we use A_i to denote its i-th row, A^i to denote its i-th column, $\|A\|_F$ to denote the Frobenius norm of A, and $\|A\|_2$ to denote the spectral norm of A. For any $n' \leq n$, we define $\xi^{(n')} \in \mathbb{R}^n$ to be a vector $\xi^{(n')} = \frac{1}{\sqrt{n'}}(1, 1, \cdots, 1, 0, 0, \cdots, 0)$.

ϵ-nets. We use the standard upper bound on size of ϵ-nets.

Definition 25.5.1. For a given set $\mathcal{S}$ and a norm $\|\cdot\|$, we say $\mathcal{N} \subseteq \mathcal{S}$ is a ϵ-net of $\mathcal{S}$ if for any $s \in \mathcal{S}$, there exists some $\overline{s} \in \mathcal{N}$ such that $\|s - \overline{s}\| \leq \epsilon$.

Lemma 25.5.1 ([Woj96, II.E, 10])**.** *Given a matrix $A \in \mathbb{R}^{n\times d}$ and a norm $\|\cdot\|$, let $\mathcal{S}$ be the unit $\|\cdot\|$-norm ball in the column space of A, i.e., $\mathcal{S} = \{Ax \mid \|Ax\| = 1\}$. For $\epsilon \in (0, 1)$, there exists an ϵ-net $\mathcal{N}$ of $\mathcal{S}$ with size $|\mathcal{N}| \leq (1 + 1/\epsilon)^d$.*

25.6 Missing Proofs in Section 25.2

In this section, we give missing proofs in Section 25.2.

We first show that if a function G satisfies Assumption 25.1.2, then G has at least linear growth. We will use this fact in later proofs.

Lemma 25.6.1. *Given a function G that satisfies property $\mathcal{P}$, then for any $0 < x \leq y$, $y/x \leq G(y)/G(x)$.*

Proof. Due to the convexity of G and $G(0) = 0$, for any $y > x > 0$, we have

$$G(x) \leq G(y)x/y + G(0)(1 - x/y) = G(y)x/y.$$

□

25.6.1 Proof of Lemma 25.2.1

Proof. The first condition is clear from the definition of $\|x\|_{G,w}$.

Now we prove the second condition. When $\|x + y\|_{G,w} = 0$, the triangle inequality clearly holds since $\|x\|_{G,w} \geq 0$ and $\|y\|_{G,w} \geq 0$. When $\|x\|_{G,w} = 0$ and $\|x + y\|_{G,w} \neq 0$, for any $\alpha > 0$, we have

$$\sum_{i=1}^{n} w_i G(|x_i + y_i|/\alpha) = \sum_{i|w_i>0} w_i G(|x_i + y_i|/\alpha) = \sum_{i|w_i>0} w_i G(|y_i|/\alpha) = \sum_{i=1}^{n} w_i G(|y_i|/\alpha),$$

which implies $\|x + y\|_{G,w} = \|y\|_{G,w}$. Similarly, the second condition also holds if $\|y\|_{G,w} = 0$ and $\|x + y\|_{G,w} \neq 0$. If $\|x + y\|_{G,w} \neq 0$, $\|x\|_{G,w} \neq 0$ and $\|y\|_{G,w} \neq 0$, by definition of $\|\cdot\|_{G,w}$, we have

$$\sum_{i=1}^{n} w_i G(x_i/\|x\|_{G,w}) = 1$$

and

$$\sum_{i=1}^{n} w_i G(y_i/\|y\|_{G,w}) = 1.$$

Thus,

$$\begin{aligned}
&\sum_{i=1}^{n} w_i G\left(\frac{x_i + y_i}{\|x\|_{G,w} + \|y\|_{G,w}}\right) \\
\leq &\sum_{i=1}^{n} w_i G\left(\frac{|x_i| + |y_i|}{\|x\|_{G,w} + \|y\|_{G,w}}\right) && (G \text{ is increasing}) \\
\leq &\sum_{i=1}^{n} w_i \left(\frac{\|x\|_{G,w}}{\|x\|_{G,w} + \|y\|_{G,w}} \cdot G(|x_i|/\|x\|_{G,w}) + \frac{\|y\|_{G,w}}{\|x\|_{G,w} + \|y\|_{G,w}} \cdot G(|y_i|/\|y\|_{G,w})\right) \\
& && (G \text{ is convex}) \\
=&1,
\end{aligned}$$

which implies $\|x + y\|_{G,w} \leq \|x\|_{G,w} + \|y\|_{G,w}$.

For the third condition, for any $a \in \mathbb{R}$ and $x \in \mathbb{R}^n$, if $\|x\|_{G,w} = 0$ then $\|ax\|_{G,w} = 0$. If $a = 0$, we have $\|ax\|_{G,w} = 0$. Otherwise, we have

$$\sum_{i=1}^{n} w_i G(x_i/\|x\|_{G,w}) = 1,$$

which implies

$$\sum_{i=1}^{n} w_i G\left(\frac{a \cdot x_i}{|a|\|x\|_{G,w}}\right) = 1,$$

and thus $\|ax\|_{G,w} = |a|\|x\|_{G,w}$. □

25.6.2 Proof of Lemma 25.2.2

Proof. Let $g \in \mathbb{R}^d$ be a vector whose entries are i.i.d. Gaussian random variables with zero mean and standard deviation 10^2. We show that with probability at least 0.8,

$$\sum_{i=1}^{n} G(\|U_i\|_2) \leq O\left(\sum_{i=1}^{n} G(\langle U_i, g\rangle)\right) \leq O\left(\max\{1, C_G\|Ug\|_G^2\}\right) \leq O(C_G d \kappa_G^2).$$

We divide our proofs into three parts.

Part I We will show that with probability at least 0.9,

$$\sum_{i=1}^{n} G(\|U_i\|_2) \leq O\left(\sum_{i=1}^{n} G(\langle U_i, g\rangle)\right).$$

For each $i \in [n]$, $\langle U_i, g\rangle$ has the same distribution as $10^2 \cdot \|U_i\|_2 \cdot \mathcal{N}(0,1)$. For each $i \in [n]$, we let B_i be the random variable such that

$$B_i = \begin{cases} 1 & |\langle U_i, g\rangle| \leq \|U_i\|_2 \\ 0 & \text{otherwise} \end{cases}.$$

By tail inequalities of standard Gaussian random variables, $\Pr[B_i = 1] \leq 0.01$. Thus,

$$\mathbb{E}\left[B_i \cdot G(\|U_i\|_2)\right] \leq 0.01 \cdot G(\|U_i\|_2),$$

which implies

$$\mathbb{E}\left[\sum_{i=1}^{n} B_i \cdot G(\|U_i\|_2)\right] \leq 0.01 \cdot \sum_{i=1}^{n} G(\|U_i\|_2),$$

By the monotonicity of G, since

$$G(\langle U_i, g\rangle) \geq (1 - B_i) G(\|U_i\|_2),$$

we have

$$\sum_{i=1}^{n} G(\langle U_i, g\rangle) \geq \sum_{i=1}^{n} (1 - B_i) G(\|U_i\|_2).$$

By Markov's inequality, with probability at least 0.9, we have

$$\sum_{i=1}^{n} B_i \cdot G(\|U_i\|_2) \leq 0.1 \sum_{i=1}^{n} G(\|U_i\|_2),$$

which implies

$$\sum_{i=1}^{n} G(\langle U_i, g\rangle) \geq 0.9 \sum_{i=1}^{n} G(\|U_i\|_2).$$

Part II We will show that

$$\sum_{i=1}^{n} G(\langle U_i, g\rangle) \leq \max\{1, C_G \cdot \|Ug\|_G^2\}.$$

When $\|Ug\|_G \leq 1$, by monotonicity of G, we must have

$$\sum_{i=1}^{n} G(\langle U_i, g\rangle) \leq 1.$$

When $\|Ug\|_G \geq 1$, we have

$$\sum_{i=1}^{n} G(\langle U_i, g\rangle / \|Ug\|_G) = 1.$$

Since

$$G(\langle U_i, g\rangle) \leq G(\langle U_i, g\rangle / \|Ug\|_G) \cdot C_G \|Ug\|_G^2$$

and

$$\sum_{i=1}^{n} G(\langle U_i, g\rangle / \|Ug\|_G) = 1,$$

we must have

$$\sum_{i=1}^{n} G(\langle U_i, g\rangle) \leq \sum_{i=1}^{n} G(\langle U_i, g\rangle / \|Ug\|_G) \cdot C_G \cdot \|Ug\|_G^2 \leq C_G \cdot \|Ug\|_G^2.$$

Part III We will show that $\|Ug\|_G^2 \leq O(C_G d \kappa_G^2)$. By definition of a well-conditioned basis and tail inequalities of Gaussian random variables, with probability at least 0.9, we have

$$\|Ug\|_G \leq \kappa_G \|g\|_2 \leq O(\kappa_G \sqrt{d}).$$

Thus, applying a union bound over three parts of the proof, we have with probability at least 0.8,

$$\sum_{i=1}^{n} G(\|U_i\|_2) \leq O(C_G d \kappa_G^2). \tag{25.9}$$

However, the condition in (25.9) is deterministic. Thus, the condition in (25.9) always holds. □

25.6.3 Proof of Lemma 25.2.3

Proof. Notice that for any $x \in \mathbb{R}^d$,

$$\|AR^{-1}x\|_G \leq \|\Pi AR^{-1}x\|_2 = \kappa\|Qx\|_2 = \kappa\|x\|_2$$

and

$$\|AR^{-1}x\|_G \geq \frac{1}{\kappa}\|\Pi AR^{-1}x\|_2 = \|Qx\|_2 = \|x\|_2.$$

□

25.6.4 Proof of Lemma 25.2.4

Proof. In Theorem 2.13 of [Woo14b], it has been shown how to calculate $\{l_i\}_{i=1}^n$ such that $l_i = \Theta(\|(AR^{-1})_i\|_2)$ in $\widetilde{O}(\text{nnz}(A) + \text{poly}(d))$ time with probability at least 0.99. We simply take $u_i = G(l_i)$. By Lemma 25.6.1 and the growth condition of G, we must have $u_i = \Theta(G(\|(AR^{-1})_i\|_2))$. □

25.6.5 Proof of Lemma 25.2.5

Proof. By homogeneity, we only need to prove that with probability $1 - \delta$, for all x which satisfies $\|Ux\|_G = 1$,

$$(1-\epsilon)\|Ux\|_G \leq \|Ux\|_{G,w} \leq (1+\epsilon)\|Ux\|_G.$$

We first prove that for any fixed $x \in \mathbb{R}^d$ such that $\|Ux\|_G = 1$, with probability $1 - \delta(1 + 4/\epsilon)^{-d}$,

$$(1-\epsilon/4)\|Ux\|_G \leq \|Ux\|_{G,w} \leq (1+\epsilon/4)\|Ux\|_G.$$

Let $x \in \mathbb{R}^d$ that satisfies $\|Ux\|_G = 1$ and $y = Ux$. Let Z_i be a random variable which denotes the value of $w_i G(y_i)$ and $Z = \sum_{i=1}^n Z_i$.

We will first show that if $Z \in [1-\epsilon/4, 1+\epsilon/4]$, then $\|y\|_{G,w} \in [1-\epsilon/4, 1+\epsilon/4]$. There are three cases:

1. If $\|y\|_{G,w} = 1$, then $\|y\|_{G,w}$ is already in $[1-\epsilon/4, 1+\epsilon/4]$.

2. If $\|y\|_{G,w} > 1$, then by Lemma 25.6.1, we have

$$\sum_{i=1}^n w_i G(y_i) \geq \sum_{i=1}^n w_i \|y\|_{G,w} \cdot G(y_i/\|y\|_{G,w}).$$

   Since

$$\sum_{i=1}^n w_i \cdot G(y_i/\|y\|_{G,w}) = 1,$$

   we must have

$$\|y\|_{G,w} \leq \sum_{i=1}^n w_i G(y_i) = Z \leq 1 + \epsilon/4.$$

3. If $\|y\|_{G,w} < 1$, then by Lemma 25.6.1, we have

$$1 = \sum_{i=1}^n w_i G(y_i/\|y\|_{G,w}) \geq 1/\|y\|_{G,w} \cdot \sum_{i=1}^n w_i G(y_i),$$

   which implies

$$\|y\|_{G,w} \geq \sum_{i=1}^n w_i G(y_i) = Z \geq 1 - \epsilon/4.$$

Thus, it suffices to prove that

$$\Pr\left[Z \in [1-\epsilon/4, 1+\epsilon/4]\right] \geq 1 - \delta(1+4/\epsilon)^{-d}.$$

Consider the expectation of Z, we have

$$\begin{aligned}\mathbb{E}[Z] &= \sum_{i=1}^{n} \mathbb{E}[Z_i] \\ &= \sum_{i=1}^{n} \mathbb{E}[w_i] \cdot G((Ux)_i) \\ &= \sum_{i=1}^{n} G((Ux)_i) \\ &= 1,\end{aligned}$$

where the last equality follows since $\|Ux\|_G = 1$.

Notice that $|Z_i - \mathbb{E}(Z_i)|$ is always upper bounded by

$$\begin{aligned}w_i G(y_i) &= w_i G((Ux)_i) \\ &\leq w_i G(\|U_i\|_2 \cdot \|x\|_2) \\ &\leq w_i G\left(\|U_i\|_2\right) \\ &\leq G\left(\|U_i\|_2\right)/p_i \\ &\leq \frac{\epsilon^2}{C\left(\log(1/\delta) + d\log(1/\epsilon)\right)},\end{aligned}$$

where the first inequality follows from Cauchy-Schwarz inequality, the second inequality follows from the definition of well-conditioned basis in Definition 25.1.2 and monotonicity of G, the third inequality follows from definition of w_i and the last inequality follows from the choice of p_i.

Consider the variance of Z, we have:

$$\begin{aligned}
\mathbb{V}(Z) &= \sum_{i|p_i<1} \mathbb{V}(Z_i) \\
&\leq \sum_{i|p_i<1} \mathbb{E}(Z_i^2) \\
&= \sum_{i|p_i<1} \left(G((Ux)_i)\right)^2 / p_i \\
&\leq \left(\sum_{i|p_i<1} G((Ux)_i)\right) \cdot \max_{i|p_i<1} G((Ux)_i)/p_i \\
&\leq \frac{\epsilon^2}{C\left(\log(1/\delta) + d\log(1/\epsilon)\right)},
\end{aligned}$$

where the second inequality follows from Hölder's inequality and the last inequality follows from the upper bound of $G((Ux)_i)/p_i$ and $\|Ux\|_G = 1$.

Thus, by Bernstein inequality, we have:

$$\Pr\left(|Z - 1| > \epsilon/4\right) \leq (1 + 4/\epsilon)^{-d}\delta.$$

Thus, for a fixed x, with probability at least $1 - (1 + 4/\epsilon)^{-d}\delta$, we have

$$(1 - \epsilon/4)\|Ux\|_G \leq \|Ux\|_{G,w} \leq (1 + \epsilon/4)\|Ux\|_G.$$

Let $\mathcal{S}$ be the unit $\|\cdot\|_G$-norm ball in the column space of U, i.e., $\mathcal{S} = \{Ux \mid \|Ux\|_G = 1\}$. According to Lemma 25.5.1, there exists an $\epsilon/4$-net $\mathcal{N}$ of $\mathcal{S}$ with $|\mathcal{N}| \leq (1 + 4/\epsilon)^d$. We use $\mathcal{E}$ to denote the event that for all $y \in \mathcal{N}$, $\|y\|_{G,w} \in [1 - \epsilon/4, 1 + \epsilon/4]$. By taking union bound over all vectors in $\mathcal{N}$, we have $\Pr[\mathcal{E}] \geq 1 - \delta$.

Conditioned on $\mathcal{E}$, now we show that for all $y \in \mathcal{S}$, $\|y\|_{G,w} \in [1 - \epsilon, 1 + \epsilon]$. Consider a

fixed vector $y \in \mathcal{S}$, since $\mathcal{N}$ is an $\epsilon/4$-net of $\mathcal{S}$, we can choose a vector $u^{(1)} \in \mathcal{N}$ such that

$$\|y - u^{(1)}\|_G \leq \epsilon/4.$$

Thus, we have that

$$\begin{aligned}\|y\|_{G,w} &\leq \|u^{(1)}\|_{G,w} + \|y - u^{(1)}\|_{G,w} \\ &\leq (1 + \epsilon/4) + \|y - u^{(1)}\|_{G,w}.\end{aligned}$$

Let $\alpha^{(1)} = 1/\|y - u^{(1)}\|_G$. Then we have $\alpha^{(1)}(y - u^{(1)}) \in \mathcal{S}$. Thus, there exist $u^{(2)} \in \mathcal{N}$ such that

$$\|u^{(2)} - \alpha^{(1)}(y - u^{(1)})\|_G \leq \epsilon/4.$$

It implies that

$$\begin{aligned}\|(y - u^{(1)}) - u^{(2)}/\alpha^{(1)}\|_G &\leq \epsilon/(4\alpha^{(1)}) \\ &\leq (\epsilon/4)^2.\end{aligned}$$

Thus,

$$\begin{aligned}\|y - u^{(1)}\|_{G,w} &\leq \|u^{(2)}\|_{G,w}/\alpha^{(1)} + \|y - u^{(1)} - u^{(2)}/\alpha^{(1)}\|_{G,w} \\ &\leq (1 + \epsilon/4)\epsilon/4 + \|y - u^{(1)} - u^{(2)}/\alpha^{(1)}\|_{G,w}.\end{aligned}$$

Let $\alpha^{(2)} = 1/\|y - u^{(1)} - u^{(2)}/\alpha^{(1)}\|_G$. Then we can repeat the above argument and get

$$\begin{aligned}\|y\|_{G,w} &\leq (1 + \epsilon/4) + (1 + \epsilon/4)\epsilon/4 + (1 + \epsilon/4)(\epsilon/4)^2 + \cdots \\ &= (1 + \epsilon/4)/(1 - \epsilon/4) \\ &\leq 1 + \epsilon.\end{aligned}$$

By applying the above upper bound on $\|\alpha^{(1)}(u^{(1)} - y)\|_{G,w}$, we can get

$$\begin{aligned}
\|y\|_{G,w} &\geq \|u^{(1)}\|_{G,w} - \|u^{(1)} - y\|_{G,w} \\
&\geq (1 - \epsilon/4) - \|u^{(1)} - y\|_{G,w} \\
&\geq (1 - \epsilon/4) - \frac{1+\epsilon}{\alpha^{(1)}} \\
&\geq 1 - \epsilon/2 - \epsilon^2/4 \\
&\geq 1 - \epsilon.
\end{aligned}$$

Thus, conditioned on $\mathcal{E}$, which holds with probability $1 - \delta$, we have $\|y\|_{G,w} \in [1 - \epsilon, 1 + \epsilon]$ for all $y = Ux$ with $\|y\|_G = 1$. □

25.6.6 Proof of Theorem 25.2.6

Proof. We first analyze the running time of the algorithm. In Step 1, we calculate $\Pi\mathbf{Ab}$ and invoke QR-decomposition on $\Pi\mathbf{Ab}$. In Step 2, we apply the algorithm in Lemma 25.2.4, which runs in $\widetilde{O}(\mathrm{nnz}(A) + \mathrm{poly}(d))$ time. Obtaining the weight vector $w \in \mathbb{R}^n$ in Step 3 requires $O(n)$ time.

Since for all $x \in \mathbb{R}^d$,

$$\|\mathbf{Ab}x\|_G \leq \|\Pi\mathbf{Ab}x\|_2 \leq \kappa\|\mathbf{Ab}x\|_G.$$

we have

$$\begin{aligned}
\mathbb{E}[\|w\|_0] = \sum_{i=1}^{n} p_i &= \sum_{i=1}^{n} O\left(d\log(1/\epsilon)/\epsilon^2 \cdot G\left(\|(\mathbf{Ab}R^{-1})_i\|_2\right)\right) \\
&\leq O\left(d\log(1/\epsilon)/\epsilon^2 \cdot C_G d\left(\kappa_G(\mathbf{Ab}R^{-1})\right)^2\right) && \text{(Lemma 25.2.2)} \\
&\leq O\left(C_G d^2\kappa^2\log(1/\epsilon)/\epsilon^2\right). && \text{(Lemma 25.2.3)}
\end{aligned}$$

By Markov's inequality, with constant probability we have $\|w\|_0 \leq O\left(C_G d^2 \kappa^2 \log(1/\epsilon)/\epsilon^2\right)$. Moreover, in order to solve $\min_x \|Ax - b\|_{G,w}$, we can ignore all rows of A with zero weights, and thus there are at most $O\left(C_G d^2 \kappa^2 \log(1/\epsilon)/\epsilon^2\right)$ remaining rows in A. Furthermore, as we show in Lemma 25.2.1, $\|\cdot\|_{G,w}$ is a seminorm, which implies we can solve $\min_x \|Ax - b\|_{G,w}$ in $\mathrm{poly}(C_G d\kappa/\epsilon)$ time, by simply solve a convex program with size $O\left(C_G d^2 \kappa^2 \log(1/\epsilon)/\epsilon^2\right)$.

Now we prove the correctness of the algorithm. The algorithm in Lemma 25.2.4 succeeds with constant probability. By Lemma 25.2.5, with constant probability, simultaneously for all $x \in \mathbb{R}^{d+1}$,

$$(1 - \epsilon/3)\|\mathbf{Ab}R^{-1}x\|_G \leq \|\mathbf{Ab}R^{-1}x\|_{G,w} \leq (1 + \epsilon/3)\|\mathbf{Ab}R^{-1}x\|_G.$$

Equivalently, with constant probability, simultaneously for all $x \in \mathbb{R}^{d+1}$,

$$(1 - \epsilon/3)\|\mathbf{Ab}x\|_G \leq \|\mathbf{Ab}x\|_{G,w} \leq (1 + \epsilon/3)\|\mathbf{Ab}x\|_G.$$

Since $x^* = \mathrm{argmin}_x \|Ax - b\|_{G,w}$, for all $x \in \mathbb{R}^d$, we have

$$\begin{aligned}
\|Ax^* - b\|_G &\leq 1/(1 - \epsilon/3)\|Ax^* - b\|_{G,w} \\
&\leq 1/(1 - \epsilon/3)\|Ax - b\|_{G,w} \\
&\leq (1 + \epsilon/3)/(1 - \epsilon/3)\|Ax - b\|_G \\
&\leq (1 + \epsilon)\|Ax - b\|_G
\end{aligned}$$

for sufficiently small ϵ. Thus, x^* is a $(1 + \epsilon)$-approximate solution to $\min_x \|Ax - b\|_G$.

Note that the failure probability of the algorithm can be reduced to an arbitrarily small constant by independent repetitions and taking the best solution found among all repetitions. □

25.7 Missing Proofs in Section 25.3

In this section, we give missing proofs in Section 25.3.

Without loss of generality, throughout this section, for the symmetric norm $\|\cdot\|_\ell$ under consideration, we assume $\|\xi^{(1)}\|_\ell = 1$.

25.7.1 Background

25.7.1.1 Known ℓ_2 Oblivious Subspace Embeddings

In this section, we recall some known ℓ_2 subspace embeddings.

Definition 25.7.1. We say $S \in \mathbb{R}^{t\times n}$ is an ℓ_2 subspace embedding for the column space of $A \in \mathbb{R}^{n\times d}$, if for all $x \in \mathbb{R}^d$,

$$(1-\epsilon)\|Ax\|_2 \le \|SAx\|_2 \le (1+\epsilon)\|Ax\|_2.$$

Definition 25.7.2. A CountSketch embedding is defined to be $\Pi = \Phi D \in \mathbb{R}^{m\times n}$ with $m = \Theta(d^2/\epsilon^2)$, where D is an $n \times n$ random diagonal matrix with each diagonal entry independently chosen to be $+1$ or -1 with equal probability, and $\Phi \in \{0,1\}^{m\times n}$ is an $m \times n$ binary matrix with $\Phi_{h(i),i} = 1$ and all remaining entries being 0, where $h : [n] \to [m]$ is a random map such that for each $i \in [n]$, $h(i) = j$ with probability $1/m$ for each $j \in [m]$.

Theorem 25.7.1 ([CW13])**.** *For a given matrix $A \in \mathbb{R}^{n\times d}$ and $\epsilon \in (0, 1/2)$. Let $\Pi \in \mathbb{R}^{\Theta(d^2/\epsilon^2)\times n}$ be a CountSketch embedding. With probability at least 0.9999, Π is an ℓ_2 subspace embedding for the column space of A. Furthermore, ΠA can be computed in $O(\mathrm{nnz}(A))$ time.*

Definition 25.7.3. A Gaussian embedding S is defined to be $\frac{1}{\sqrt{m}} \cdot G \in \mathbb{R}^{m\times n}$ with $m = \Theta(d/\epsilon^2)$, where each entry of $G \in \mathbb{R}^{m\times n}$ is chosen independently from the standard Gaussian distribution.

Theorem 25.7.2 ([Woo14b]). *For a given matrix $A \in \mathbb{R}^{n\times d}$ and $\epsilon \in (0, 1/2)$. Let $S \in \mathbb{R}^{\Theta(d/\epsilon^2)\times n}$ be a Gaussian embedding. With probability at least 0.9999, S is an ℓ_2 subspace embedding for the column space of A.*

Definition 25.7.4. A composition of Gaussian embedding and CountSketch embedding is defined to be $S' = S\Pi$, where $\Pi \in \mathbb{R}^{\Theta(d^2/\epsilon^2)\times n}$ is a CountSketch embedding and $S \in \mathbb{R}^{\Theta(d/\epsilon^2)\times\Theta(d^2/\epsilon^2)}$ is a Gaussian embedding.

The following corollary directly follows from the above two theorems.

Corollary 25.7.3. *For a given matrix $A \in \mathbb{R}^{n\times d}$ and $\epsilon \in (0, 1/2)$. Let $S' \in \mathbb{R}^{\Theta(d/\epsilon^2)\times n}$ be a composition of Gaussian embedding and CountSketch embedding. With probability at least 0.9998, S' is an ℓ_2 subspace embedding for the column space of A. Furthermore, $S'A$ can be computed in $O(\mathrm{nnz}(A) + d^4/\epsilon^4)$ time.*

We remark that all ℓ_2 subspace embeddings introduced in this section are *oblivious*, meaning that the distribution of the embedding matrix does not depend on the matrix A.

25.7.1.2 Properties of Symmetric Norms

General Properties. We first introduce several general properties of symmetric norms.

Lemma 25.7.4 (Lemma 2.1 in [BBC+17]). *For any symmetric norm $\|\cdot\|_\ell$ and $x, y \in \mathbb{R}^n$ such that for all $i \in [n]$ we have $|x_i| \leq |y_i|$, then $\|x\|_\ell \leq \|y\|_\ell$.*

Lemma 25.7.5 (Fact 2.2 in [BBC+17]). *Suppose $\|\xi^{(1)}\|_\ell = 1$, for any vector $x \in \mathbb{R}^n$,*

$$\|x\|_\infty \leq \|x\|_\ell \leq \|x\|_1.$$

Lemma 25.7.6 (Lemma 3.12 in [BBC+17]). *Let $\|\cdot\|_\ell$ be a symmetric norm. Then*

$$\Omega(M_\ell/\sqrt{\log n}) \le \|\xi^{(n)}\|_\ell \le O(M_\ell),$$

where M_ℓ is as defined in Definition 25.3.2.

Modulus of Approximation. We need the following quantity of a symmetric norm.

Definition 25.7.5. The *maximum modulus of approximation* of a symmetric norm $\|\cdot\|_\ell$ is defined as

$$\mathrm{mma}(\ell, r) = \max_{1\le a\le b\le ar\le n} \frac{M_{\ell(ar)}}{M_{\ell(b)}},$$

where $\|\cdot\|_{\ell(k)}$ is a norm on $\mathbb{R}^k$ which is defined to be

$$\|(x_1, x_2, \cdots, x_k)\|_{\ell(k)} = \|(x_1, x_2, \cdots, x_k, 0, \cdots, 0)\|_\ell,$$

and $M_{\ell(k)}$ is as defined in Definition 25.3.2.

Intuitively, $\mathrm{mma}(\ell, r)$ characterizes how well the original symmetric norm can be approximated by a lower dimensional induced norm. We show in the following lemma that $\mathrm{mma}(\ell, r) \le O(\sqrt{r \log n})$ for any symmetric norm.

Lemma 25.7.7. *For any symmetric norm $\|\cdot\|_\ell$ and $r \in [n]$, $\mathrm{mma}(\ell, r) \le O(\sqrt{r \log n})$.*

Proof. By Lemma 25.7.6, for any $i \in [n]$, $\Omega(M_{\ell(i)}/\sqrt{\log n}) \le \|\xi^{(i)}\|_\ell \le O(M_{\ell(i)})$. Let $ar = c_1 b + c_2$, where c_1, c_2 are non-negative integers with $c_1 \le ar/b$ and $c_2 \le b$. Observe that we can rewrite $\xi^{(ar)}$ as

$$\xi^{(ar)} = \left[\frac{\sqrt{b}}{\sqrt{ar}} \cdot \left(\underbrace{\xi^{(b)}, \xi^{(b)}, \xi^{(b)}, \ldots, \xi^{(b)}}_{c_1 \text{ times}}\right), \frac{\sqrt{c_2}}{\sqrt{ar}}\xi^{(c_2)}, 0, \ldots, 0\right].$$

Therefore, by triangle inequality, we have

$$\begin{aligned}
\|\xi^{(ar)}\|_\ell &\le \frac{\sqrt{b}}{\sqrt{ar}} \cdot c_1 \cdot \|\xi^{(b)}\|_\ell + \frac{\sqrt{c_2}}{\sqrt{ar}} \cdot \|\xi^{(c_2)}\|_\ell \\
&\le \sqrt{\frac{b}{ar}} \cdot \frac{ar}{b} \cdot \|\xi^{(b)}\|_\ell + \frac{\sqrt{b}}{\sqrt{ar}} \cdot \|\xi^{(b)}\|_\ell && (c_1 \le ar/b \text{ and } c_2 \le b) \\
&\le \sqrt{r} \cdot \|\xi^{(b)}\|_\ell + \|\xi^{(b)}\|_\ell && (a \le b \le ar) \\
&\le 2\sqrt{r} \cdot \|\xi^{(b)}\|_\ell. && (r \ge 1)
\end{aligned}$$

Now we apply Lemma 25.7.6 on both sides, which implies

$$\frac{M_{\ell^{(ar)}}}{\sqrt{\log n}} \le O(\sqrt{r} \cdot M_{\ell^{(b)}})$$

as desired. □

Properties of SymSketch. Now we introduce several properties of SymSketch.

The following lemma shows that for a data matrix $A \in \mathbb{R}^d$, calculating SA requires $\widetilde{O}(\mathrm{nnz}(A) + \mathrm{poly}(d))$ time for a SymSketch S.

Lemma 25.7.8. *For a given matrix $A \in \mathbb{R}^{n\times d}$, let $S \in \mathbb{R}^{O(d)\times n}$ be a SymSketch as in Definition 25.3.1. SA can be computed in $O(\mathrm{nnz}(A)) + \mathrm{poly}(d)$ time in expectation, and in $O(\mathrm{nnz}(A)\log n) + \mathrm{poly}(d)$ time in the worst case.*

Proof. Since S is a SymSketch, $S = \Pi\widetilde{D} = \Pi \cdot \begin{bmatrix} w_0 D_0 \\ w_1 D_1 \\ \vdots \\ w_t D_t \end{bmatrix}$, where $\Pi \in \mathbb{R}^{O(d)\times O(n\log n)}$. Since D_i is a diagonal matrix, $\mathrm{nnz}(D_i A) \le \mathrm{nnz}(A)$, and thus $\mathrm{nnz}(\widetilde{D}A) \le (t+1)\cdot\mathrm{nnz}(A) = O(\mathrm{nnz}(A)\log n)$, which implies $\widetilde{D}A$ can be computed in $(t+1)\cdot\mathrm{nnz}(A) = O(\mathrm{nnz}(A)\log n)$ time.

On the other hand, the expected number of nonzero entries of $D_i A$ is $2^{-i}\,\mathrm{nnz}(A)$. Thus, $\widetilde{D}A$ has $O(\mathrm{nnz}(A))$ nonzero entries in expectation, which implies $\widetilde{D}A$ can be computed in $O(\mathrm{nnz}(A))$ time.

Finally, notice that Π is a composition of Gaussian embedding and CountSketch embedding, which implies $\Pi\widetilde{D}A$ can be computed in $\mathrm{nnz}(\widetilde{D}A) + \mathrm{poly}(d)$ time. □

The following lemma shows that with constant probability, for all $x \in \mathbb{R}^n, \|Sx\|_2 \leq \mathrm{poly}(n)\|x\|_2$.

Lemma 25.7.9. *Let $S \in \mathbb{R}^{O(d)\times n}$ be a SymSketch as defined in Definition 25.3.1, then with probability at least 0.9999 $\|S\|_2 \leq \mathrm{poly}(n)$.*

Proof. Notice that $S = \Pi\widetilde{D}$, since $\|S\|_2 \leq \|\Pi\|_2 \cdot \|\widetilde{D}\|_2$, it suffices to bound $\|\Pi\|_2$ and $\|\widetilde{D}\|_2$. Since Π is a composition of Gaussian embedding and CountSketch embedding (Definition 25.7.4), with probability at least $0.9999, \|\Pi\|_2 \leq \|\Pi\|_F \leq \mathrm{poly}(n)$. Now consider $\widetilde{D} = \begin{bmatrix} w_0 D_0 \\ w_1 D_1 \\ \vdots \\ w_t D_t \end{bmatrix}$. By Lemma 25.7.5, for all $j \in [t], w_j \leq \mathrm{poly}(n)$. Furthermore, $\|D_j\|_2 \leq 1$ and $t = \Theta(\log n)$, which implies $\|\widetilde{D}\|_2 \leq \mathrm{poly}(n)$. □

Throughout this whole section we assume that for any non-zero vector $x \in \mathbb{R}^n$, we have $1 \leq |x_j| \leq \mathrm{poly}(n)$ for all $j \in [n]$. Notice that this assumption is without loss of generality, as shown in the following lemma.

Lemma 25.7.10. *For any non-zero vector $x \in \mathbb{R}^n$, let $\overline{x} \in \mathbb{R}^n$ be a vector with $\overline{x} = \frac{\text{poly}(n) \cdot x}{\|x\|_\infty}$, and $x' \in \mathbb{R}^n$ where*

$$x'_i = \begin{cases} \overline{x}_i & \text{if } \overline{x}_i \geq 1 \\ 0 & \text{otherwise} \end{cases}.$$

For a symmetric norm $\|\cdot\|_\ell$, suppose $\|S\|_2 \leq \text{poly}(n)$ and

$$\alpha \|x'\|_\ell \leq \|Sx'\|_2 \leq \beta \|x'\|_\ell$$

for some $\alpha, \beta \in [1/\text{poly}(n), \text{poly}(n)]$, then

$$\Omega(\alpha)\|x\|_\ell \leq \|Sx\|_2 \leq O(\beta)\|x\|_\ell.$$

Proof. By triangle inequality and Lemma 25.7.4, we have

$$\|\overline{x}\|_\ell - n \leq \|x'\|_\ell \leq \|\overline{x}\|_\ell.$$

By Lemma 25.7.5,

$$\|x'\|_\ell \geq \|x'\|_\infty = \|\overline{x}\|_\infty = \text{poly}(n),$$

we have

$$(1 - 1/\text{poly}(n))\|\overline{x}\|_\ell \leq \|x'\|_\ell \leq \|\overline{x}\|_\ell.$$

Notice that $\|S\overline{x}\|_2 = \|Sx' + S(\overline{x} - x')\|_2$. By triangle inequality we have

$$\|Sx'\|_2 - \|S\|_2\|\overline{x} - x'\|_2 \leq \|S\overline{x}\|_2 \leq \|Sx'\|_2 + \|S\|_2\|\overline{x} - x'\|_2.$$

By the given conditions, we have

$$(1 - 1/\text{poly}(n))\|Sx'\|_2 \leq \|S\overline{x}\|_2 \leq (1 + 1/\text{poly}(n))\|Sx'\|_2,$$

which implies

$$\Omega(\alpha)\|\overline{x}\|_\ell \leq \|S\overline{x}\|_2 \leq O(\beta)\|\overline{x}\|_\ell.$$

Since $\overline{x} = \frac{\text{poly}(n)\cdot x}{\|x\|_\infty}$, we have

$$\Omega(\alpha)\|x\|_\ell \leq \|Sx\|_2 \leq O(\beta)\|x\|_\ell.$$

□

By Lemma 25.7.10, we can focus on those non-zero vectors $x \in \mathbb{R}^n$ such that $1 \leq |x_j| \leq \text{poly}(n)$ for all $j \in [n]$.

Definition 25.7.6. For a given vector $x \in \mathbb{R}^n$, suppose for all $j \in [n]$,

$$1 \leq |x_j| \leq \text{poly}(n).$$

Let $g = \Theta(\log n)$. For each $i \in \{0, 1, \ldots, g\}$, we define

$$L_i(x) = \{j \mid 2^i \leq |x_j| < 2^{i+1}\}.$$

For each $i \in \{0, 1, \ldots, g\}$, we define $V_i(x) \in \mathbb{R}^n$ to be the vector

$$V_i(x) = (\underbrace{2^i, 2^i, \ldots, 2^i}_{|L_i(x)|}, 0, \ldots, 0).$$

For each $i \in \{0, 1, \ldots, g\}$, we say a level i to be *contributing* if

$$\|V_i(x)\|_\ell \geq \Omega\left(1/g\right) \cdot \|x\|_\ell.$$

Lemma 25.7.11. *Let $g = \Theta(\log n)$. For a given vector $x \in \mathbb{R}^n$ such that for all $j \in [n], 1 \leq |x_j| \leq 2^g$, there exists at least one level $i \in \{0, 1, \cdots, g\}$ which is contributing.*

Proof. If none of $i \in \{0, 1, \cdots, g\}$ is contributing, then $\|x\|_\ell \leq \sum_{i=0}^{g} \|V_i(x)\|_\ell \leq 1/(2g) \cdot \sum_{i=0}^{g} \|x\|_\ell \leq \frac{1}{2}\|x\|_\ell$, which leads to a contradiction. □

25.7.2 Proof of Lemma 25.3.1

Proof. Consider a fixed $n' \in [n]$. By Lemma 25.7.6, we have

$$M_{\ell_a^{(n')}} = \Omega\left(\|\xi^{(n')}\|_{\ell_a^{(n')}}\right) = \Omega\left(1 + c\sqrt{n'}\right)$$

and

$$M_{\ell_b^{(n')}} = \Omega\left(\|\xi^{(n')}\|_{\ell_b^{(n')}}\right) = \Omega\left(\max\left(1, c\sqrt{n'}\right)\right).$$

It is also straightforward to verify that

$$\max_{x \in \mathbb{S}^{n'-1}} \|x\|_{\ell_a} = 1 + c\sqrt{n'}$$

and

$$\max_{x \in \mathbb{S}^{n'-1}} \|x\|_{\ell_b} = \max\left(1, c\sqrt{n'}\right).$$

Taking the ratio between $\max_{x \in \mathbb{S}^{n'-1}} \|x\|_\ell$ and $M_{\ell^{(n')}}$ for $\ell \in \{\ell_a, \ell_b\}$, we complete the proof. □

25.7.3 Proof of Lemma 25.3.2

Proof. Let $\overline{G}(x) = \sqrt{x} \cdot G^{-1}(1/x)$, where $G^{-1}(1/x)$ is the unique value in $[0, \infty)$ such that $G(G^{-1}(1/x)) = 1/x$. We first show that $\overline{G}(x)$ is an approximately decreasing function for $x \in (0, \infty)$. Let m, n be two real numbers with $0 < m \leq n$. We have $1/n \leq 1/m$, which implies $0 < G^{-1}(1/n) \leq G^{-1}(1/m)$ by monotonicity of G. By the third condition in Assumption 25.1.2, we have

$$\frac{G(G^{-1}(1/m))}{G(G^{-1}(1/n))} \leq C_G \cdot \left(\frac{G^{-1}(1/m)}{G^{-1}(1/n)}\right)^2,$$

which implies

$$\sqrt{n} \cdot G^{-1}(1/n) \leq \sqrt{C_G} \cdot \sqrt{m} \cdot G^{-1}(1/m).$$

Hence $\overline{G}(n) \le \sqrt{C_G} \cdot \overline{G}(m)$.

We are now ready to prove the lemma. Recall that for the Orlicz norm $\|\cdot\|_\ell = \|\cdot\|_G$, we have

$$\mathrm{mmc}(\ell) = \max_{n' \in [n]} \mathrm{mc}(\ell^{(n')}) = \max_{n' \in [n]} \frac{\max_{x \in \mathbb{S}^{n'-1}} \|x\|_{\ell^{(n')}}}{M_{\ell^{(n')}}}.$$

By Lemma 25.7.6, we have,

$$\Omega(1) \cdot \|\xi^{(n')}\|_{\ell^{(n')}} \le M_{\ell^{(n')}} \le O(\sqrt{\log n}) \cdot \|\xi^{(n')}\|_{\ell^{(n')}}.$$

Thus $\|\xi^{(n')}\|_{\ell^{(n')}}$ provides an approximation to $M_{\ell^{(n')}}$. By definition of $\|\cdot\|_G$, we have

$$\|\xi^{(n')}\|_{\ell^{(n')}} = \frac{1}{\sqrt{n'} \cdot G^{-1}(1/n')} = \frac{1}{\overline{G}(n')}.$$

Hence

$$\Omega(1) \le M_{\ell^{(n')}} \cdot \overline{G}(n') \le O(\sqrt{\log n}).$$

Next, we compute $\max_{x \in \mathbb{S}^{n'-1}} \|x\|_{\ell^{(n')}}$. For an arbitrary unit vector $x \in \mathbb{S}^{n'-1}$, we denote

$$B_j = \{i \in [n] : |x_i| \in [1/2^j, 1/2^{j-1})\}$$

and $b_j = |B_j|$. For each j, let $x^{B_j} \in \mathbb{R}^n$ be the vector such that

$$x_i^{B_j} = \begin{cases} x_i & \text{if } j \in B_j \\ 0 & \text{otherwise} \end{cases}.$$

Note that non-zero coordinates in x^{B_j} have magnitude close to each other (within a factor

of 2), we thus have

$$\begin{aligned}\|x^{B_j}\|_\ell &= \|x^{B_j}\|_2 \cdot \left\| \frac{x^{B_j}}{\|x^{B_j}\|_2} \right\|_\ell \\ &\le \frac{\sqrt{b_j}}{2^{j-1}} \cdot \left\| \frac{x^{B_j}}{\|x^{B_j}\|_2} \right\|_\ell \\ &\le \frac{\sqrt{b_j}}{2^{j-2}} \cdot \|\xi^{(b_j)}\|_{\ell^{(b_j)}} \\ &= \frac{\sqrt{b_j}}{2^{j-2}} \cdot \frac{1}{\overline{G}(b_j)}.\end{aligned}$$

Similarly,

$$\begin{aligned}\|x^{B_j}\|_\ell &\ge \frac{\sqrt{b_j}}{2^{j+2}} \cdot \|\xi^{(b_j)}\|_{\ell^{(b_j)}} \\ &= \frac{\sqrt{b_j}}{2^{j+2}} \cdot \frac{1}{\overline{G}(b_j)} \\ &\ge \frac{\sqrt{b_j}}{2^{j+2}} \cdot \frac{1}{\sqrt{C_G} \cdot \overline{G}(1)}.\end{aligned}$$

We claim there exists an constant $c > 0$ such that

$$\sum_{\substack{j > c \log n \\ b_j > 0}} \|x^{B_j}\|_\ell \le \sum_{j' \le c \log n} \|x^{B^{j'}}\|_\ell.$$

To show this, by Lemma 25.6.1, for any $b \ge 1$,

$$b = \frac{G(G^{-1}(1))}{G(G^{-1}(1/b))} \ge \frac{G^{-1}(1)}{G^{-1}(1/b)},$$

which implies

$$G^{-1}(1/b) \ge \frac{G^{-1}(1)}{b}.$$

Next, since $\|x\|_2 = 1$, there exists an $0 \le \widetilde{j} \le 4 \log n$ such that $b_{\widetilde{j}} \ge 1$. Therefore,

$$\|x^{B_{\widetilde{j}}}\|_\ell \ge \frac{1}{2^{\widetilde{j}+2}} \cdot \frac{1}{\sqrt{C_G} \cdot \overline{G}(1)}.$$

Thus, we have

$$\begin{aligned}
\sum_{\substack{j>c\log n\\ b_j>0}} \|x^{B_j}\|_\ell &= \sum_{\substack{j>c\log n\\ b_j>0}} \|x^{B_j}\|_2 \cdot \left\| \frac{x^{B_j}}{\|x^{B_j}\|_2} \right\|_\ell \\
&\le \sum_{\substack{j>c\log n\\ b_j>0}} \frac{\sqrt{n}}{2^{j-2}} \cdot \|\xi^{(b_j)}\|_{\ell^{(b_j)}} \\
&\le \sum_{\substack{j>c\log n\\ b_j>0}} \frac{\sqrt{n}}{2^{j-2}} \cdot \frac{1}{\sqrt{b_j} G^{-1}(1/b_j)} \\
&\le n \cdot \frac{\sqrt{n}}{2^{c\log n-2}} \cdot \frac{b_j}{\sqrt{b_j} G^{-1}(1)} \\
&\le n \cdot 2^{\widetilde{j}+2} \cdot \frac{\sqrt{n}}{2^{c\log n-2}} \cdot \sqrt{C_G n} \cdot \|x^{B_{\widetilde{j}}}\|_\ell \\
&\le \|x^{B_{\widetilde{j}}}\|_\ell \\
&\le \sum_{j'\le c\log n} \|x^{B^{j'}}\|_\ell
\end{aligned}$$

for some sufficiently large constant c.

Let

$$j^* = \mathrm{argmax}_{j\le c\log n} \|x^{B_j}\|_\ell,$$

we have

$$\begin{aligned}
\|x^{B_{j^*}}\|_\ell \le \|x\|_\ell &\le \sum_{j\le c\log n} \|x^{B_j}\|_\ell + \sum_{\substack{j>c\log n\\ b_j>0}} \|x^{B_j}\|_\ell \\
&\le 2 \sum_{j\le c\log n} \|x^{B_j}\|_\ell \\
&\le O(\log n) \cdot \|x^{B_{j^*}}\|_\ell.
\end{aligned}$$

Thus,

$$\begin{aligned}
\max_{x\in\mathbb{S}^{n'-1}} \|x\|_{\ell^{(n')}} &\le O(\log n') \max_{x\in\mathbb{S}^{n'-1}} \|x^{B_{j^*}}\|_\ell \\
&\le O(\log n') \max_{x\in\mathbb{S}^{n'-1}} \|x^{B_{j^*}}\|_2 \cdot \left\| \frac{x^{B_{j^*}}}{\|x^{B_{j^*}}\|_2} \right\|_\ell \\
&\le O(\log n') \max_{x\in\mathbb{S}^{n'-1}} \left\| \frac{x^{B_j}}{\|x^{B_j}\|_2} \right\|_\ell \\
&\le O(\log n') \max_{b_{j^*}\le n'} \|\xi^{(b_j)}\|_{\ell^{(b_j)}} \\
&\le O(\log n') \max_{b_{j^*}\le n'} \frac{1}{\overline{G}(b_{j^*})} \\
&\le \frac{O(\sqrt{C_G}\log n')}{\overline{G}(n')}.
\end{aligned}$$

Thus, we have

$$\begin{aligned}
\mathrm{mmc}(\ell) &= \max_{n'\in[n]} \frac{\max_{x\in\mathbb{S}^{n'-1}} \|x\|_{\ell^{(n')}}}{M_{\ell^{(n')}}} \\
&\le O(\sqrt{C_G}\log n).
\end{aligned}$$

□

25.7.4 Contraction Bound of SymSketch

In this section we give the contraction bound of SymSketch. We first show that for a fixed vector $x \in \mathbb{R}^n$, $\|\widetilde{D}x\|_2 \ge 1/\operatorname{poly}(d\log n)\cdot\|x\|_\ell$ with probability $1-2^{-\Theta(d\log n)}$.

Lemma 25.7.12. *Let $\widetilde{D}$ be the matrix defined in Definition 25.3.1. For any fixed $x\in\mathbb{R}^n$, with probability $1-2^{-\Theta(d\log n)}$,*

$$\|\widetilde{D}x\|_2 \ge 1/\alpha_0 \cdot \|x\|_\ell,$$

where $\alpha_0 = O(\mathrm{mma}(\ell,d)\cdot\log^{5/2} n) = O(\sqrt{d}\log^3 n)$.

Proof. The lemma follows from the following two claims. Recall that $t = \Theta(\log n)$.

Claim 25.7.13. *For any fixed $x \in \mathbb{R}^n$. If there is a contributing level $i^* \in \{0, 1, 2, \ldots, g\}$ such that $|L_{i^*}(x)| = \Theta(d \log n) \cdot 2^j$ for some $j \in [t]$, then with probability at least $1 - 2^{-\Theta(d \log n)}$,*

$$\|w_j D_j x\|_2 \geq \Omega\left(\frac{1}{\mathrm{mma}(\ell, d) \cdot \log^{5/2} n}\right) \|x\|_\ell.$$

Proof. Let y_h be a random variable such that

$$y_h = \begin{cases} 1 & \text{if the } h\text{-th diagonal entry of } D_j \text{ is } 1 \\ 0 & \text{otherwise} \end{cases}.$$

Let $Y = \sum_{h \in L_{i^*}(x)} y_h$. By Chernoff bound, we have

$$\Pr[Y \geq \Omega(d \log n)] \geq 1 - 2^{-\Theta(d \log n)}.$$

Conditioned on $Y \geq \Omega(d \log n)$, we have

$$\begin{aligned}
\frac{\|w_j D_j x\|_2}{\|x\|_\ell} &= \frac{w_j \|D_j x\|_2}{\|x\|_\ell} \\
&\geq \frac{2^{i^*} w_j \sqrt{d \log n}}{\|x\|_\ell} \\
&\geq \frac{2^{i^*} \sqrt{2^j} M_{\ell(2^j)} \sqrt{d \log n}}{2^{i^*+1} g M_{\ell(|L_{i^*}(x)|)} \sqrt{\log n} \sqrt{|L_{i^*}(x)|}} \\
&\geq \Omega(1/\log^{3/2} n) \cdot \frac{M_{\ell(2^j)}}{M_{\ell(|L_{i^*}(x)|)}} \\
&= \Omega(1/\log^{3/2} n) \cdot \frac{M_{\ell(2^j)}}{M_{\ell(|L_{i^*}(x)|/\log n)}} \cdot \frac{M_{\ell(|L_{i^*}(x)|/\log n)}}{M_{\ell(|L_{i^*}(x)|)}} \\
&\geq \Omega\left(\frac{1}{\mathrm{mma}(\ell, d) \cdot \mathrm{mma}(\ell, \log n) \cdot \log^{3/2} n}\right) \\
&\geq \Omega\left(\frac{1}{\mathrm{mma}(\ell, d) \cdot \log^{5/2} n}\right).
\end{aligned}$$

Here the first inequality follows from the fact that there are at least $\Omega(d \log n)$ coordinates sampled from $L_{i^*}(x)$. The second inequality follows from Lemma 25.7.6 and the fact that level i^* is a contributing level. The third inequality follows from $|L_{i^*}(x)| = \Theta(d \log n) \cdot 2^j$ and $g = \Theta(\log n)$. The forth inequality follows from Definition 25.7.5. The last inequality follows from Lemma 25.7.7. □

Claim 25.7.14. *For any fixed $x \in \mathbb{R}^n$. If there is a contributing level $i^* \in \{0, 1, 2, \ldots, g\}$ such that $|L_{i^*}(x)| = O(d \log n)$, then we have*

$$\|w_0 D_0 x\|_2 \geq \Omega\left(\frac{1}{\mathrm{mma}(\ell, d) \cdot \log^{5/2} n}\right) \|x\|_\ell.$$

Proof.

$$\begin{aligned}
\frac{\|w_0 D_0 x\|_2}{\|x\|_\ell} &= \frac{w_0 \|x\|_2}{\|x\|_\ell} \\
&\geq \frac{2^{i^*} w_0 \sqrt{|L_{i^*}(x)|}}{\|x\|_\ell} \\
&\geq \frac{2^{i^*} M_{\ell(1)} \sqrt{|L_{i^*}(x)|}}{2^{i^*+1} g M_{\ell(|L_{i^*}(x)|)} \sqrt{\log n} \sqrt{|L_{i^*}(x)|}} \\
&\geq \Omega(1/\log^{3/2} n) \cdot \frac{M_{\ell(1)}}{M_{\ell(|L_{i^*}(x)|/\log n)}} \cdot \frac{M_{\ell(|L_{i^*}(x)|/\log n)}}{M_{\ell(|L_{i^*}(x)|)}} \\
&\geq \Omega\left(\frac{1}{\mathrm{mma}(\ell, d) \cdot \log^{5/2} n}\right)
\end{aligned}$$

The first inequality follows from the fact that we only consider the contribution of the coordinates in $L_{i^*}(x)$. The second inequality follows from Lemma 25.7.6 and the fact that level i^* is a contributing level. The third inequality follows from $g = \Theta(\log n)$. The last inequality follows from Definition 25.7.5 and Lemma 25.7.7. □

By Claim 25.7.13 and Claim 25.7.14, since any vector $x \in \mathbb{R}^n$ contains at least one contributing level, with probability at least $1 - 2^{-\Theta(d \log n)}$ we have $\|\widetilde{D}x\|_2 \geq \Omega(1/(\mathrm{mma}(\ell, d) \cdot \log^{5/2} n)) \cdot \|x\|_\ell$. We complete the proof by combining this with Lemma 25.7.7. □

Now we show how to combine the contraction bound in Lemma 25.7.12 with a net argument to give a contraction bound for all vectors in a subspace.

Lemma 25.7.15. *Let $S \in \mathbb{R}^{O(d) \times n}$ be a random matrix. For any $\alpha_0 = \mathrm{poly}(n)$ and $A \in \mathbb{R}^{n \times d}$, if*

1. *$\|S\|_2 \leq \mathrm{poly}(n)$ holds with probability at least 0.999;*
2. *for any fixed $x \in \mathbb{R}^n$, $\|Sx\|_2 \geq 1/\alpha_0 \cdot \|x\|_\ell$ holds with probability $1 - e^{-Cd \log n}$ for a sufficiently large constant C,*

then with probability at least 0.998, for all $y \in \mathbb{R}^n$ in the column space of A,

$$\|Sy\|_2 \geq \Omega(1/\alpha_0)\|y\|_\ell.$$

Proof. For the matrix $A \in \mathbb{R}^{n \times d}$, we define the set $\mathcal{B} = \{y \mid y = Ax, \|y\|_2 = 1\}$. We define $\mathcal{N} \subset \mathbb{R}^n$ to be an ϵ-net of $\mathcal{B}$ as in Definition 25.5.1. By Lemma 25.5.1, we have $|\mathcal{N}| \leq (1 + 1/\epsilon)^d$, and for all $y \in \mathcal{B}$, there exists $z \in \mathcal{N}$ such that $\|y - z\|_2 \leq \epsilon$. We take $\epsilon = 1/\mathrm{poly}(n)$ here.

Due to the second condition, since $|\mathcal{N}| \leq e^{O(d \log n)}$, by taking union bound over all vectors in $\mathcal{N}$, we know that with probability $1 - e^{-\Theta(d \log n)}$, for all $z \in \mathcal{N}$, $\|Sz\|_2 \geq 1/\alpha_0 \cdot \|z\|_\ell$.

Now, for any vector $y \in \mathcal{B}$, there exists $z \in \mathcal{N}$ such that $\|y - z\|_2 \leq 1/\operatorname{poly}(n)$, and we define $w = y - z$.

$$
\begin{aligned}
\|Sy\|_2 &= \|S(z+w)\|_2 \\
&\geq \|Sz\|_2 - \|Sw\|_2 && \text{(triangle inequality)} \\
&\geq 1/\alpha_0 \cdot \|z\|_\ell - \|Sw\|_2 && \text{(by the second condition)} \\
&\geq 1/\alpha_0 \cdot \|z\|_\ell - \|S\|_2 \|w\|_2 && (\|Sw\|_2 \leq \|S\|_2 \cdot \|w\|_2) \\
&\geq 1/\alpha_0 \cdot \|z\|_\ell - \operatorname{poly}(n) \cdot \|w\|_2 && \text{(by the first condition)} \\
&\geq 1/\alpha_0 \cdot \|y - w\|_\ell - \operatorname{poly}(n) \cdot \|w\|_2 && (y = z + w) \\
&\geq 1/\alpha_0 \cdot \|y\|_\ell - 1/\alpha_0 \cdot \|w\|_\ell - \operatorname{poly}(n) \cdot \|w\|_2 && \text{(triangle inequality)} \\
&\geq 1/\alpha_0 \cdot \|y\|_\ell - 1/\alpha_0 \cdot \sqrt{n}\|w\|_2 - \operatorname{poly}(n) \cdot \|w\|_2 && \text{(Lemma 25.7.5)} \\
&\geq 1/\alpha_0 \cdot \|y\|_\ell - (1/\alpha_0 \cdot \sqrt{n} + \operatorname{poly}(n))\epsilon && (\|w\|_2 \leq \epsilon) \\
&\geq 0.5/\alpha_0 \cdot \|y\|_\ell.
\end{aligned}
$$

□

Lemma 25.7.16. *For a given matrix $A \in \mathbb{R}^{n \times d}$. Let $S \in \mathbb{R}^{O(d) \times n}$ be a SymSketch as defined in Definition 25.3.1. With probability at least 0.995, for all $x \in \mathbb{R}^d$, $\|SAx\|_2 \geq 1/\alpha_0 \cdot \|Ax\|_\ell$ where $\alpha_0 = O(\sqrt{d}\log^3 n)$.*

Proof. By Lemma 25.7.12 and Lemma 25.7.9, the two conditions in Lemma 25.7.15 are satisfied. By Lemma 25.7.15, with probability at least 0.998, for all $x \in \mathbb{R}^d$, $\|\widetilde{D}Ax\|_2 \geq \Omega(1/\alpha_0)\|Ax\|_\ell$. Since $\Pi \in \mathbb{R}^{O(d) \times n(t+1)}$ is a composition of Gaussian embedding and CountSketch embedding with $\epsilon = 0.1$, by Corollary 25.7.3, with probability at least 0.999, for all

$x \in \mathbb{R}^d$, $\|\Pi\widetilde{D}Ax\|_2 \geq \Omega(\|\widetilde{D}Ax\|_2)$. By a union bound, we know that with probability at least 0.995, for all $x \in \mathbb{R}^d$, $\|SAx\|_2 \geq \Omega(1/\alpha_0)\|Ax\|_\ell$. □

25.7.5 Dilation Bound of SymSketch

In this section we give the dilation bound of SymSketch. We first show that for any fixed $x \in \mathbb{R}^n$, with high probability, $\|\widetilde{D}x\|_2 \leq \mathrm{poly}(d \log n) \cdot \mathrm{mmc}(\ell) \cdot \|x\|_\ell$.

Lemma 25.7.17. *Let $\widetilde{D}$ be the matrix defined in Definition 25.3.1. For any fixed vector $x \in \mathbb{R}^n$, with probability $1 - \delta$, $\|\widetilde{D}x\|_2 \leq \alpha_1/\delta \cdot \|x\|_\ell$, where $\alpha_1 = O(\mathrm{mmc}(\ell) \log^{5/2} n)$.*

Proof. Consider a fixed vector $x \in \mathbb{R}^n$. Recall that $t = \Theta(\log n)$. Let $c > 0$ be a fixed constant. We define the j-heavy level set H_j as

$$H_j = \left\{ i \;\middle|\; |L_i(x)| \geq c\frac{\delta 2^j}{\log^2 n}, 0 \leq i \leq g \right\}.$$

Let $\overline{H}_j$ be the j-light level set, i.e., $\overline{H}_j = \{0, 1, \ldots, g\} \backslash H_j$. Notice that

$$\sum_{i \in \overline{H}_j} |L_i(x)| \cdot 2^{-j} \leq g \cdot c\delta 2^j / \log^2 n \cdot 2^{-j} \leq O(\delta / \log n).$$

By Markov's inequality, with probability at least $1 - \delta/(2t)$, no element from a j-light level is sampled by D_j, i.e., for all $i \in \overline{H}_j, k \in L_i(x)$, the k-th diagonal entry of D_j is 0. By taking union bound over all $j \in [t]$, with probability at least $1 - \delta/2$, for all $j \in [t]$, no element from a j-light level is sampled by D_j. Let ζ denote this event. We condition on this event in the remaining part of the proof. In the following analysis, we show an upper bound of $\|w_j D_j x\|_2^2$ for each $j \in [t]$. Let H_j be the set of j-heavy levels.

Consider a fixed $j \in [t]$, we have

$$\begin{aligned}
\mathop{\mathbb{E}}_{D_j}\left[\|w_j D_j x\|_2^2 \;\middle|\; \zeta\right] &= w_j^2 \mathop{\mathbb{E}}_{D_j}\left[\|D_j x\|_2^2 \middle| \zeta\right] \\
&= w_j^2 \mathop{\mathbb{E}}_{D_j}\left[\sum_{h=1}^{n} (D_j(h,h))^2 x_h^2 \;\middle|\; \zeta\right] \\
&= w_j^2 \mathop{\mathbb{E}}_{D_j}\left[\sum_{i=0}^{g} \sum_{h \in L_i(x)} (D_j(h,h))^2 x_h^2 \;\middle|\; \zeta\right] \\
&= w_j^2 \frac{1}{2^j} \sum_{i \in H_j} \sum_{h \in L_i(x)} x_h^2 \\
&\leq w_j^2 \frac{1}{2^j} \sum_{i \in H_j} |L_i(x)| \cdot (2^{i+1})^2.
\end{aligned}$$

Claim 25.7.18. $w_j^2 2^{-j} \leq O((M_{\ell^{(2^j)}})^2)$.

Proof.

$$\begin{aligned}
w_j^2 2^{-j} &= (\|(1,1,\ldots,1,0,\ldots,0)\|_\ell)^2 \cdot 2^{-j} \\
&= \left(\left\|\frac{1}{\sqrt{2^j}}(1,1,\ldots,1,0,\ldots,0)\right\|_\ell \sqrt{2^j}\right)^2 \cdot 2^{-j} \\
&= (\|\xi^{(2^j)}\|_\ell)^2 \cdot 2^j \cdot 2^{-j} \\
&= (\|\xi^{(2^j)}\|_\ell)^2 \\
&\leq O(M_{\ell^{(2^j)}}),
\end{aligned}$$

where the third step follows from the definition of $\xi^{(2^j)}$, and the last step follows from Lemma 25.7.6. □

Using the above claim, we have

$$
\begin{aligned}
& w_j^2 \sum_{i \in H_j} |L_i(x)| \cdot 2^{2i-j} \\
= & \sum_{i \in H_j} \frac{w_j^2 2^{-j}}{(M_{\ell(|L_i(x)|)})^2} \cdot |L_i(x)| \cdot (M_{\ell(|L_i(x)|)})^2 \cdot 2^{2i} \\
\leq & O\left(\sum_{i \in H_j} \left(\frac{M_{\ell(2^j)}}{M_{\ell(|L_i(x)|)}} \right)^2 \cdot |L_i(x)| \cdot (M_{\ell(|L_i(x)|)})^2 \cdot 2^{2i} \right) \\
\leq & O\left(\sum_{i \in H_j} \left(\frac{M_{\ell(2^j)}}{M_{\ell(|L_i(x)|)}} \right)^2 w_{\log |L_i(x)|}^2 \log n \cdot 2^{2i} \right) \\
= & \log n \cdot \underbrace{\sum_{i \in H_j, |L_i(x)| \leq 2^j} \left(\frac{M_{\ell(2^j)}}{M_{\ell(|L_i(x)|)}} \right)^2 \cdot w_{\log |L_i(x)|}^2 \cdot 2^{2i}}_{\diamondsuit} \\
& + \log n \cdot \underbrace{\sum_{i \in H_j, |L_i(x)| > 2^j} \left(\frac{M_{\ell(2^j)}}{M_{\ell(|L_i(x)|)}} \right)^2 \cdot w_{\log |L_i(x)|}^2 \cdot 2^{2i}}_{\heartsuit},
\end{aligned}
$$

where the second step follows from $w_j^2 2^{-j} \leq O((M_{\ell(2^j)})^2)$ (Claim 25.7.18), and the third step follows from $|L_i(x)| \cdot (M_{\ell(|L_i(x)|)})^2 \leq O(w_{\log |L_i(x)|}^2 \log n)$ (Lemma 25.7.6). It remains to upper bound $\diamondsuit$ and $\heartsuit$.

To given an upper bound for $\diamondsuit$, we have

$$\begin{aligned}
\diamondsuit &\leq O\left(\sum_{i\in H_j, |L_i(x)|\leq 2^j} \mathrm{mma}^2(\ell, \log^2 n/\delta)\cdot w^2_{\log|L_i(x)|}\cdot 2^{2i}\right)\\
&\leq O\left(\mathrm{mma}^2(\ell,\log^2 n/\delta)\left(\sum_{i=0}^{g} w_{\log|L_i(x)|}\cdot 2^i\right)^2\right)\\
&\leq O\left(\mathrm{mma}^2(\ell,\log^2 n/\delta)\right)\|x\|_\ell^2\\
&\leq O(\log^3 n/\delta)\|x\|_\ell^2,
\end{aligned}$$

where the first step follows from the definition of mma, the second step follows from Minkowski inequality, the third step follows from the definition of $L_i(x)$, $w_{\log|L_i(x)|}$ and triangle inequality, the last step follows from Lemma 25.7.7.

To give an upper bound for $\heartsuit$, we have

$$\begin{aligned}
\heartsuit &\leq O\left(\log n\cdot\sum_{i\in H_j, |L_i(x)|>2^j} \mathrm{mmc}^2(\ell) w^2_{\log|L_i(x)|}\cdot 2^{2i}\right)\\
&\leq O\left(\log n\cdot\mathrm{mmc}^2(\ell)\cdot\left(\sum_{i=0}^{g} w_{\log|L_i(x)|}\cdot 2^i\right)^2\right)\\
&\leq O\left(\log n\cdot\mathrm{mmc}^2(\ell)\cdot\|x\|_\ell^2\right),
\end{aligned}$$

where the first step follows from $(M_{\ell(2^j)}/M_{\ell(|L_i(x)|)})^2 \leq O(\log n\cdot\mathrm{mmc}^2(\ell))$ (Lemma 3.14 in [BBC+17]).

Putting it all together, we have

$$\mathop{\mathbb{E}}_{D_j}[\|w_j D_j x\|_2^2|\zeta] \leq \log n\cdot(\diamondsuit+\heartsuit)\leq O(\log^4 n/\delta+\log^2 n\cdot\mathrm{mmc}^2(\ell))\|x\|_\ell^2.$$

Thus,

$$\mathop{\mathbb{E}}_{\widetilde{D}}[\|\widetilde{D}x\|_2^2|\zeta] \leq \sum_{j=0}^{t} \mathop{\mathbb{E}}_{D_j}[\|w_j D_j x\|_2^2|\zeta] \leq O(\log^5 n/\delta + \log^3 n \cdot \mathrm{mmc}^2(\ell))\|x\|_\ell^2.$$

By Markov's inequality, conditioned on ζ, with probability at least $1 - \delta/2$,

$$\|\widetilde{D}x\|_2^2 \leq O(\log^5 n/\delta + \log^3 n \cdot \mathrm{mmc}^2(\ell))\|x\|_\ell^2/\delta.$$

Since ζ holds with probability at least $1 - \delta/2$, with probability at least $1 - \delta$, we have

$$\|\widetilde{D}x\|_2 \leq O(\log^{5/2} n/\delta \cdot \mathrm{mmc}(\ell)) \cdot \|x\|_\ell.$$

□

Now we show how to use the dilation bound for a fixed vector in Lemma 25.7.17 to prove a dilation bound for all vectors in a subspace. We need the following existential result in our proof.

Lemma 25.7.19 ([Aue30])**.** *Given a matrix $A \in \mathbb{R}^{n\times m}$ and a norm $\|\cdot\|$, there exists a basis matrix $U \in \mathbb{R}^{n\times d}$ of the column space of A, such that*

$$\sum_{i=1}^{d} \|U^i\| \leq d,$$

and for all $x \in \mathbb{R}^d$,

$$\|x\|_\infty \leq \|Ux\|.$$

Lemma 25.7.20. *Given a matrix $A \in \mathbb{R}^{n\times d}$. Let $S \in \mathbb{R}^{O(d)\times n}$ be a* SymSketch *as defined in Definition 25.3.1. With probability at least 0.99, for all $x \in \mathbb{R}^d$,*

$$\|SAx\|_2 \leq O(\alpha_1 d^2)\|Ax\|_\ell,$$

where $\alpha_1 = O(\mathrm{mmc}(\ell) \cdot \log^{5/2} n)$.

Proof. Recall that $S = \Pi\widetilde{D}$. Let U be a basis matrix of the column space of A as in Lemma 25.7.19. By Lemma 25.7.17, for a fixed $i \in [d]$, with probability at least $1 - 1/(100d)$, $\|\widetilde{D}U^i\|_2 \leq O(\alpha_1 d)\|U^i\|_\ell$. By taking a union bound over $i \in [d]$, with probability at least 0.999, for all $i \in [d]$, $\|\widetilde{D}U^i\|_2 \leq \alpha_1 d\|U^i\|_\ell$. Thus, for any $x \in \mathbb{R}^d$,

$$\begin{aligned}
\|\widetilde{D}Ux\|_2 \leq & \sum_{i=1}^d |x_i| \cdot \|\widetilde{D}U^i\|_2 \\
\leq & \|x\|_\infty \cdot \sum_{i=1}^d \|\widetilde{D}U^i\|_2 \\
\leq & \|Ux\|_\ell \cdot \sum_{i=1}^d \|\widetilde{D}U^i\|_2 \\
\leq & O(\alpha_1 d) \cdot \|Ux\|_\ell \cdot \sum_{i=1}^d \|U^i\|_\ell \\
\leq & O(\alpha_1 d^2) \cdot \|Ux\|_\ell,
\end{aligned}$$

where the first step follows from triangle inequality, the second step follows from $|x_i| \leq \|x\|_\infty$ for all $i \in [d]$, the third step follows from $\|x\|_\infty \leq \|Ux\|_\ell$, the fourth step follows from $\|\widetilde{D}U^i\|_2 \leq O(\alpha_1 d)\|U^i\|_\ell$, the last step follows from $\sum_{i=1}^d \|U^i\|_\ell \leq d$.

By Corollary 25.7.3, with probability at least 0.999, Π is an ℓ_2 subspace embedding with $\epsilon = 0.1$ for the column space of $\widetilde{D}U$. Thus, with probability at least 0.99, for all $x \in \mathbb{R}^d$, $\|SAx\|_2 \leq O(\alpha_1 d^2)\|Ax\|_\ell$. □

25.7.6 Proof of Theorem 25.3.3

Proof. It directly follows from Lemma 25.7.16, Lemma 25.7.20 and Lemma 25.7.8. □

25.8 Missing Proofs of Main Theorems

25.8.1 Proof of Theorem 25.1.3

Let $S \in \mathbb{R}^{O(d)\times n}$ be a SymSketch as defined in Definition 25.3.1, and $\Pi = O(\sqrt{d}\log^3 n)\cdot S$. By Corollary 25.3.4, for a given matrix $A \in \mathbb{R}^{n\times d}$, with probability at least 0.9, for all $x \in \mathbb{R}^d$,

$$\|Ax\|_G \le \|\Pi Ax\|_2 \le \kappa\|Ax\|_G,$$

where $\kappa = O(\sqrt{C_G}d^{5/2}\log^{13/2} n)$. We prove Theorem 25.1.3 by combining Theorem 25.2.6 with the embedding matrix Π constructed above.

25.8.2 Proof of Theorem 25.1.4

Let $S \in \mathbb{R}^{O(d)\times n}$ be a SymSketch as defined in Definition 25.3.1. For a given data matrix $A \in \mathbb{R}^{n\times d}$ and response vector $b \in \mathbb{R}^n$, we calculate $x^* = \operatorname{argmin}_x \|SAx - Sb\|_2$ and return x^*. The algorithm runs in $O(\mathrm{nnz}(A) + \mathrm{poly}(d))$ time, since by Lemma 25.7.8, the expected running time for calculating SA is $O(\mathrm{nnz}(A) + \mathrm{poly}(d))$, and $x^* = (SA)^+Sb$ can be calculated in $\mathrm{poly}(d)$ time.

To see the correctness, let $\overline{x} = \operatorname{argmin}_x \|Ax - b\|_\ell$. With probability at least 0.99, we have

$$\begin{aligned}
\|Ax^* - b\|_\ell &\le O(\sqrt{d}\log^3 n)\|SAx^* - Sb\|_2 \\
&\le O(\sqrt{d}\log^3 n)\|SA\overline{x} - Sb\|_2 \\
&\le O(\sqrt{d}\log^3 n)\|\widetilde{D}A\overline{x} - \widetilde{D}b\|_\ell \\
&= O(\sqrt{d}\log^{11/2} n)\cdot \mathrm{mmc}(\ell)\cdot\|A\overline{x} - b\|_\ell.
\end{aligned}$$

The first step follows by applying Lemma 25.7.16 on $\mathbf{Ab}$, where we use $\mathbf{Ab} \in \mathbb{R}^{n \times (d+1)}$ to denote a matrix whose first d columns are A and the last column is b. The second step follows from the fact that $x^* = \text{argmin}_x \|SAx - Sb\|_2$. The third step follows by Definition 25.3.1 and Corollary 25.7.3. The last step follows by applying Lemma 25.7.17 on $A\overline{x} - b$.

Chapter 26

Kronecker Product Regression

We study Kronecker product regression, in which the design matrix to a regression problem is a Kronecker product of two or more matrices. Formally, given $A_i \in \mathbb{R}^{n_i \times d_i}$ for $i = 1, 2, \ldots, q$ where $n_i \gg d_i$ for each i, and $b \in \mathbb{R}^{n_1 n_2 \cdots n_q}$, let $\mathcal{A} = A_i \otimes A_2 \otimes \cdots \otimes A_q$. Then for $p \in [1, 2]$, the goal is to find $x \in \mathbb{R}^{d_1 \cdots d_q}$ that approximately minimizes $\|\mathcal{A}x - b\|_p$. Recently, Diao, Song, Sun, and Woodruff (AISTATS, 2018) gave an algorithm which is faster than forming the Kronecker product $\mathcal{A} \in \mathbb{R}^{n_1 \cdots n_q \times d_1 \cdots d_q}$. Specifically, for $p = 2$ they achieve a running time of $O(\sum_{i=1}^{q} \text{nnz}(A_i) + \text{nnz}(b))$, where $\text{nnz}(A_i)$ is the number of non-zero entries in A_i. Note that $\text{nnz}(b)$ can be as large as $\Theta(n_1 \cdots n_q)$. For $p = 1$, $q = 2$ and $n_1 = n_2$, they achieve a worse bound of $O(n_1^{3/2}\text{poly}(d_1 d_2) + \text{nnz}(b))$. In this work, we provide significantly faster algorithms. For $p = 2$, our running time is $O(\sum_{i=1}^{q} \text{nnz}(A_i))$, which has no dependence on $\text{nnz}(b)$. For $p < 2$, our running time is $O(\sum_{i=1}^{q} \text{nnz}(A_i) + \text{nnz}(b))$, which matches the prior best running time for $p = 2$. We also consider the related all-pairs regression problem, where given $A \in \mathbb{R}^{n \times d}, b \in \mathbb{R}^n$, we want to solve $\min_{x \in \mathbb{R}^d} \|\bar{A}x - \bar{b}\|_p$, where $\bar{A} \in \mathbb{R}^{n^2 \times d}, \bar{b} \in \mathbb{R}^{n^2}$ consist of all pairwise differences of the rows of A, b. We give an $O(\text{nnz}(A))$ time algorithm for $p \in [1, 2]$, improving the $\Omega(n^2)$ time required to form $\bar{A}$. Finally, we initiate the study of Kronecker product low rank approximation and low-trank approximation. For input $\mathcal{A}$ as above, we give an $O(\sum_{i=1}^{q} \text{nnz}(A_i))$ time algorithm, which is much faster than computing $\mathcal{A}$.

2023

This part is based upon the following previous publication

- Huaian Diao, Rajesh Jayaram, Zhao Song, Wen Sun, David P. Woodruff
  Optimal Sketching for Kronecker Product Regression and Low Rank Approximation.
  Manuscript 2019 [DJS+19]

26.1 Introduction

In the q-th order Kronecker product regression problem, one is given $A_i \in \mathbb{R}^{n_i \times d_i}$ for each $i \in \{1, 2, \ldots, q\}$, together with $b \in \mathbb{R}^{n_1 n_2 \cdots n_q}$, and the goal is to obtain a solution to the optimization problem:

$$\min_{x \in \mathbb{R}^{d_1 d_2 \cdots d_q}} \|(A_1 \otimes A_2 \cdots \otimes A_q)x - b\|_p,$$

where $p \in [1, 2]$, and for a vector $x \in \mathbb{R}^n$ the ℓ_p norm is defined by $\|x\|_p = (\sum_{i=1}^n |x_i|^p)^{1/p}$. For $p = 2$, this is least squares regression, and for $p = 1$ this is least absolute deviation regression.

Kronecker product regression is a special case of ordinary regression, in which the design matrix is highly structured. Namely, it is the Kronecker product of two or more matrices. Kronecker product matrices naturally arise in applications such as spline regression, signal processing, and multivariate data fitting. We refer the reader to [VL92, VLP93, GVL13] for further background and applications of Kronecker product regression. As discussed in [DSSW18], Kronecker product regression also arises in structured blind deconvolution problems [OY05], and the bivariate problem of surface fitting and multidimensional density smoothing [EM06].

A recent work of Diao, Song, Sun, and Woodruff [DSSW18] utilizes *sketching* techniques to output an $x \in \mathbb{R}^{d_1 d_2 \cdots d_q}$ with objective function at most $(1+\epsilon)$-times larger than optimal, for both least squares and least absolute deviation Kronecker product regression. Importantly, their time complexity is faster than the time needed to explicitly compute $A_1 \otimes \cdots \otimes A_q$. We note that sketching itself is a powerful tool for compressing extremely high dimensional data, and has been used in a number of tensor related problems, e.g., [SWZ16, LHW17, DSSW18, SWZ19b].

For least squares regression, [DSSW18] achieve $O(\sum_{i=1}^{q} \text{nnz}(A_i) + \text{nnz}(b) + \text{poly}(d/\epsilon))$ time, where $\text{nnz}(C)$ for a matrix C denotes the number of non-zero entries of C. Note that the focus is on the over-constrained regression setting, when $n_i \gg d_i$ for each i, and so the goal is to have a small running time dependence on the n_i. We remark that over-constrained regression has been the focus of a large body of work over the past decade, which primarily attempts to design fast regression algorithms in the big data (large sample size) regime, see, e.g., [Mah11b, Woo14b] for surveys.

Observe that explicitly computing $A_1 \otimes \cdots \otimes A_q$ would take $\prod_{i=1}^{q} \text{nnz}(A_i)$ time, which can be as large as $\prod_{i=1}^{q} n_i d_i$, and so the results of [DSSW18] offer a large computational advantage. Unfortunately, since $b \in \mathbb{R}^{n_1 n_2 \cdots n_q}$, we can have $\text{nnz}(b) = \prod_{i=1}^{q} n_i$, and therefore $\text{nnz}(b)$ is likely to be the dominant term in the running time. This leaves open the question of whether it is possible to solve this problem in time *sub-linear* in $\text{nnz}(b)$, with a dominant term of $O(\sum_{i=1}^{q} \text{nnz}(A_i))$.

For least absolute deviation regression, the bounds of [DSSW18] achieved are still an improvement over computing $A_1 \otimes \cdots \otimes A_q$, though worse than the bounds for least squares regression. The authors focus on $q = 2$ and the special case $n = n_1 = n_2$. Here, they obtain

a running time of $O(n^{3/2}\,\mathrm{poly}(d_1 d_2/\epsilon) + \mathrm{nnz}(b))$[1]. This leaves open the question of whether an *input-sparsity* $O(\mathrm{nnz}(A_1) + \mathrm{nnz}(A_2) + \mathrm{nnz}(b) + \mathrm{poly}(d_1 d_2/\epsilon))$ time algorithm exists.

In this work, we also study the related all-pairs regression problem. Given $A \in \mathbb{R}^{n\times d}, b \in \mathbb{R}^n$, the goal is to approximately solve the ℓ_p regression problem $\min_x \|\bar{A}x - \bar{b}\|_p$, where $\bar{A} \in \mathbb{R}^{n^2\times d}$ is the matrix formed by taking all pairwise differences of the rows of A (and $\bar{b}$ is defined similarly). For $p = 1$, this is known as the *rank regression estimator*, which has a long history in statistics. It is closely related to the renowned Wilconxon rank test [WL09], and enjoys the desirable property of being robust with substantial efficiency gain with respect to heavy-tailed random errors, while maintaining high efficiency for Gaussian errors [WKL09, WL09, WPB+18, Wan19a]. In many ways, it has properties more desirable in practice than that of the Huber M-estimator [WPB+18, Wan19b]. Recently, the all-pairs loss function was also used by [WPB+18] as an alternative approach to overcoming the challenges of tuning parameter selection for the Lasso algorithm. However, the rank regression estimator is computationally intensive to compute, even for moderately sized data, since the standard procedure (for $p = 1$) is to solve a linear program with $O(n^2)$ constraints. In this work, we demonstrate the first highly efficient algorithm for this estimator.

Finally, in addition to regression, we extend our techniques to the Low Rank Approximation (LRA) problem. Here, given a large data matrix A, the goal is to find a low rank matrix B which well-approximates A. LRA is useful in numerous applications, such as

[1]We remark that while the $\mathrm{nnz}(b)$ term is not written in the Theorem of [DSSW18], their approach of leverage score sampling from a well-conditioned basis requires one to sample from a well conditioned basis of $[A_1 \otimes A_2, b]$ for a subspace embedding. As stated, their algorithm only sampled from $[A_1 \otimes A_2]$. To fix this omission, their algorithm would require an additional $\mathrm{nnz}(b)$ time to leverage score sample from the augmented matrix.

compressing massive datasets to their primary components for storage, denoising, and fast matrix-vector products. Thus, designing fast algorithms for approximate LRA has become a large and highly active area of research; see [Woo14b] for a survey. For an incomplete list of recent work using sketching techniques for LRA, see [CW13, MM13, NN13a, BW14, CW15b, CW15a, RSW16, BWZ16, SWZ17, MW17, CGK+17c, LHW17, SWZ18, BW18, SWZ19b, BBB+19b, IVWW19] and the references therein.

Motivated by the importance of LRA, we initiate the study of low-rank approximation of Kronecker product matrices. Given q matrices $A_1, \cdots A_q$ where $A_i \in \mathbb{R}^{n_i \times d_i}$, $n_i \gg d_i$, $A = \otimes_{i=1}^{q} A_i$, the goal is to output a rank-k matrix $B \in \mathbb{R}^{n \times d}$ such that $\|B - A\|_F^2 \leq (1+\epsilon)\,\mathrm{OPT}_k$, where OPT_k is the cost of the best rank-k approximation, $n = n_1 \cdots n_q$, and $d = d_1 \cdots d_q$. Here $\|A\|_F^2 = \sum_{i,j} A_{i,j}^2$. The fastest general purpose algorithms for this problem run in time $O(\mathrm{nnz}(A) + \mathrm{poly}(dk/\epsilon))$ [CW13]. However, as in regression, if $A = \otimes_{i=1}^{q} A_i$, we have $\mathrm{nnz}(A) = \prod_{i=1}^{q} \mathrm{nnz}(A_i)$, which grows very quickly. Instead, one might also hope to obtain a running time of $O(\sum_{i=1}^{q} \mathrm{nnz}(A_i) + \mathrm{poly}(dk/\epsilon))$.

26.1.1 Our Contributions

Our main contribution is an input sparsity time $(1+\epsilon)$-approximation algorithm to Kronecker product regression for every $p \in [1, 2]$, and $q \geq 2$. Given $A_i \in \mathbb{R}^{n_i \times d_i}$, $i = 1, \ldots, q$, and $b \in \mathbb{R}^n$ where $n = \prod_{i=1}^{q} n_i$, together with accuracy parameter $\epsilon \in (0, 1/2)$ and failure probability $\delta > 0$, the goal is to output a vector $x' \in \mathbb{R}^d$ where $d = \prod_{i=1}^{q} d_i$ such that $\|(A_1 \otimes \cdots \otimes A_q)x' - b\|_p \leq (1+\epsilon)\min_x \|(A_1 \otimes \cdots \otimes A_q)x - b\|_p$ holds with probability at least $1 - \delta$. For $p = 2$, our algorithm runs in $\widetilde{O}(\sum_{i=1}^{q} \mathrm{nnz}(A_i)) + \mathrm{poly}(d\delta^{-1}/\epsilon))$ time[2]. Notice

[2]For a function $f(n, d, \epsilon, \delta)$, $\widetilde{O}(f) = O(f \cdot \mathrm{poly}(\log n))$, where we assume $n \geq d, \epsilon^{-1}, \delta^{-1}$

that this is *sub-linear* in the input size, since it does not depend on $\mathrm{nnz}(b)$. For $p < 2$, the running time is $\widetilde{O}((\sum_{i=1}^{q} \mathrm{nnz}(A_i) + \mathrm{nnz}(b) + \mathrm{poly}(d/\epsilon)) \log(1/\delta))$.

Observe that in both cases, this running time is significantly faster than the time to write down $A_1 \otimes \cdots \otimes A_q$. For $p = 2$, up to logarithmic factors, the running time is the same as the time required to simply read each of the A_i. Moreover, in the setting $p < 2$, $q = 2$ and $n_1 = n_2$ considered in [DSSW18], our algorithm offers a substantial improvement over their running time of $O(n^{3/2} \mathrm{poly}(d_1 d_2/\epsilon))$.

We empirically evaluate our Kronecker product regression algorithm on exactly the same datasets as those used in [DSSW18]. For $p \in \{1, 2\}$, the accuracy of our algorithm is nearly the same as that of [DSSW18] while the running time is significantly faster.

For the all-pairs (or rank) regression problem, we first note that for $A \in \mathbb{R}^{n \times d}$, one can rewrite $\bar{A} \in \mathbb{R}^{n^2 \times d}$ as the difference of Kronecker products $\bar{A} = A \otimes \mathbf{1}^n - \mathbf{1}^n \otimes A$ where $\mathbf{1}^n \in \mathbb{R}^n$ is the all ones vector. Since $\bar{A}$ is not a Kronecker product itself, our earlier techniques for Kronecker product regression are not directly applicable. Therefore, we utilize new ideas, in addition to careful sketching techniques, to obtain an $\widetilde{O}(\mathrm{nnz}(A) + \mathrm{poly}(d/\epsilon))$ time algorithm for $p \in [1, 2]$, which improves substantially on the $O(n^2 d)$ time required to even compute $\bar{A}$, by a factor of at least n.

Our main technical contribution for both our ℓ_p regression algorithm and the rank regression problem is a novel and highly efficient ℓ_p sampling algorithm. Specifically, for the rank-regression problem we demonstrate, for a given $x \in \mathbb{R}^d$, how to independently sample s entries of a vector $\bar{A}x = y \in \mathbb{R}^{n^2}$ from the ℓ_p distribution $(|y_1|^p / \|y\|_p^p, \ldots, |y_{n^2}|^p / \|y\|_p^p)$ in $\widetilde{O}(nd + \mathrm{poly}(ds))$ time. For the ℓ_p regression problem, we demonstrate the same result when

$y = (A_1 \otimes \cdots \otimes A_q)x - b \in \mathbb{R}^{n_1 \cdots n_q}$, and in time $\widetilde{O}(\sum_{i=1}^{q} \text{nnz}(A_i) + \text{nnz}(b) + \text{poly}(ds))$. This result allows us to sample a small number of rows of the input to use in our sketch. Our algorithm draws from a large number of disparate sketching techniques, such as the dyadic trick for quickly finding heavy hitters [CM04, KNPW11, LNNT16, NS19], and the precision sampling framework from the streaming literature [AKO10].

For the Kronecker Product Low-Rank Approximation (LRA) problem, we give an input sparsity $O(\sum_{i=1}^{q} \text{nnz}(A_i) + \text{poly}(dk/\epsilon))$-time algorithm which computes a rank-k matrix B such that $\|B - \otimes_{i=1}^{q} A_i\|_F^2 \leq (1+\epsilon) \min_{\text{rank}-k\ B'} \|B' - \otimes_{i=1}^{q} A_i\|_F^2$. Note again that the dominant term $\sum_{i=1}^{q} \text{nnz}(A_i)$ is substantially smaller than the $\text{nnz}(A) = \prod_{i=1}^{q} \text{nnz}(A_i)$ time required to write down the Kronecker Product A, which is also the running time of state-of-the-art general purpose LRA algorithms [CW13, MM13, NN13a]. Thus, our results demonstrate that substantially faster algorithms for approximate LRA are possible for inputs with a Kronecker product structure. Our technical contributions involve demonstrating that useful properties of known sketching matrices hold also for the Kronecker product of these matrices.

In addition, motivated by [VL00], we use our techniques to solve the low-trank approximation problem, where we are given an arbitrary matrix $A \in \mathbb{R}^{n^q \times n^q}$, and the goal is to output a trank-k matrix $B \in \mathbb{R}^{n^q \times n^q}$ such that $\|B - A\|_F$ is minimized. Here, the trank of a matrix B is the smallest integer k such that B can be written as a summation of k matrices, where each matrix is the Kronecker product of q matrices with dimensions $n \times n$. Compressing a matrix A to a low-trank approximation yields many of the same benefits as LRA, such as compact representation, fast matrix-vector product, and fast matrix multiplication, and thus is applicable in many of the settings where LRA is used. Using similar

sketching ideas, we provide an $O(\sum_{i=1}^{q} \text{nnz}(A_i) + \text{poly}(d_1 \cdots d_q/\epsilon))$ time algorithm for this problem under various loss functions. Our results for low-trank approximation can be found in Section 26.11.

26.2 Preliminaries

Notation. For a tensor $A \in \mathbb{R}^{n_1 \times n_2 \times n_3}$, we use $\|A\|_p$ to denote the entry-wise ℓ_p norm of A, i.e., $\|A\|_p = (\sum_{i_1} \sum_{i_2} \sum_{i_3} |A_{i_1,i_2,i_3}|^p)^{1/p}$. For $n \in \mathbb{N}$, let $[n] = \{1, 2, \ldots, n\}$. For a matrix A, let $A_{i,*}$ denote the i-th row of A, and $A_{*,j}$ the j-th column. For $a, b \in \mathbb{R}$ and $\epsilon \in (0, 1)$, we write $a = (1 \pm \epsilon)b$ to denote $(1 - \epsilon)b \leq a \leq (1 + \epsilon)b$. We now define various sketching matrices used by our algorithms.

p-stable Transforms. We will utilize the well-known p-stable distribution, $\mathcal{D}_p$ (see [Nol07, Ind06] for further discussion), which exist for $p \in (0, 2]$. For $p \in (0, 2)$, $X \sim \mathcal{D}_p$ is defined by its characteristic function $\mathbb{E}_X[\exp(\sqrt{-1}tX)] = \exp(-|t|^p)$, and can be efficiently generated to a fixed precision [Nol07, KNW10b]. For $p = 2$, $\mathcal{D}_2$ is just the standard Gaussian distribution, and for $p = 1$, $\mathcal{D}_1$ is the *Cauchy* distribution. The distribution $\mathcal{D}_p$ has the property that if $z_1, \ldots, z_n \sim D_p$ are i.i.d., and $a \in \mathbb{R}^n$, then $\sum_{i=1}^{n} z_i a_i \sim z\|a\|_p$ where $\|a\|_p = (\sum_{i=1}^{n} |a_i|^p)^{1/p}$, and $z \sim \mathcal{D}_p$. This property will allow us to utilize sketches with entries independently drawn from $\mathcal{D}_p$ to preserve the ℓ_p norm.

Definition 26.2.1 (Dense p-stable Transform, [CDMI+13])**.** Let $p \in [1, 2]$. Let $S = \sigma \cdot C \in \mathbb{R}^{m \times n}$, where σ is a scalar, and each entry of $C \in \mathbb{R}^{m \times n}$ is chosen independently from $\mathcal{D}_p$.

We will also need a sparse version of the above.

Definition 26.2.2 (Sparse p-Stable Transform, [MM13, CDMI+13])**.** Let $p \in [1, 2]$. Let $\Pi = \sigma \cdot SC \in \mathbb{R}^{m \times n}$, where σ is a scalar, $S \in \mathbb{R}^{m \times n}$ has each column chosen independently

and uniformly from the m standard basis vectors of $\mathbb{R}^m$, and $C \in \mathbb{R}^{n \times n}$ is a diagonal matrix with diagonals chosen independently from the standard p-stable distribution. For any matrix $A \in \mathbb{R}^{n \times d}$, ΠA can be computed in $O(\mathrm{nnz}(A))$ time.

One nice property of p-stable transformations is that they provide *low-distortion ℓ_p embeddings*.

Lemma 26.2.1 (Theorem 1.4 of [WW19]; see also Theorem 2 and 4 of [MM13] for earlier work [3])**.** *Fix $A \in \mathbb{R}^{n \times d}$, and let $S \in \mathbb{R}^{k \times n}$ be a sparse or dense p-stable transform for $p \in [1, 2)$, with $k = \Theta(d^2/\delta)$. Then with probability $1 - \delta$, for all $x \in \mathbb{R}^d$:*

$$\|Ax\|_p \leq \|SAx\|_p \leq O(d \log d)\|Ax\|_p$$

We simply call a matrix $S \in \mathbb{R}^{k \times n}$ a low distortion ℓ_p embedding for $A \in \mathbb{R}^{n \times d}$ if it satisfies the above inequality for all $x \in \mathbb{R}^d$.

Leverage Scores & Well Condition Bases. We now introduce the notions of ℓ_2 leverage scores and well-conditioned bases for a matrix $A \in \mathbb{R}^{n \times d}$.

Definition 26.2.3 (ℓ_2-Leverage Scores, [Woo14b, BSS12])**.** Given a matrix $A \in \mathbb{R}^{n \times d}$, let $A = Q \cdot R$ denote the QR factorization of matrix A. For each $i \in [n]$, we define $\sigma_i = \frac{\|(AR^{-1})_i\|_2^2}{\|AR^{-1}\|_F^2}$, where $(AR^{-1})_i \in \mathbb{R}^d$ is the i-th row of matrix $(AR^{-1}) \in \mathbb{R}^{n \times d}$. We say that $\sigma \in \mathbb{R}^n$ is the ℓ_2 leverage score vector of A.

[3] In discussion with the authors of these works, the original $O((d \log d)^{1/p})$ distortion factors stated in these papers should be replaced with $O(d \log d)$; as we do not optimize the poly(d) factors in our analysis, this does not affect our bounds.

Algorithm 26.1 Our ℓ_2 Kronecker Product Regression Algorithm

  return $\widehat{x}$
end procedure

Definition 26.2.4 ((ℓ_p, α, β) Well-Conditioned Basis, [Cla05])**.** Given a matrix $A \in \mathbb{R}^{n\times d}$, we say $U \in \mathbb{R}^{n\times d}$ is an (ℓ_p, α, β) well-conditioned basis for the column span of A if the columns of U span the columns of A, and if for any $x \in \mathbb{R}^d$, we have $\alpha\|x\|_p \leq \|Ux\|_p \leq \beta\|x\|_p$, where $\alpha \leq 1 \leq \beta$. If $\beta/\alpha = d^{O(1)}$, then we simply say that U is an ℓ_p well conditioned basis for A.

Fact 26.2.2 ([WW19, MM13])**.** *Let $A \in \mathbb{R}^{n\times d}$, and let $SA \in \mathbb{R}^{k\times d}$ be a low distortion ℓ_p embedding for A (see Lemma 26.2.1), where $k = O(d^2/\delta)$. Let $SA = QR$ be the QR decomposition of SA. Then AR^{-1} is an ℓ_p well-conditioned basis with probability $1 - \delta$.*

26.3 Kronecker Product Regression

We first introduce our algorithm for $p = 2$. Our algorithm for $1 \leq p < 2$ is given in Section 26.3.1. Our regression algorithm for $p = 2$ is formally stated in Algorithm 26.1. Recall that our input design matrix is $A = \otimes_{i=1}^q A_i$, where $A_i \in \mathbb{R}^{n_i\times d_i}$, and we are also given $b \in \mathbb{R}^{n_1\cdots n_q}$. Let $n = \prod_{i=1}^q n_i$ and $d = \prod_{i=1}^q d_i$. The crucial insight of the algorithm is that one can approximately compute the leverage scores of A given only good approximations to the leverage scores of each A_i. Applying this fact gives a efficent algorithm for sampling rows of A with probability proportional to the leverage scores. Following standard arguments, we

  Compute $\widehat{x} = \arg\min_{x\in\mathbb{R}^d} \|\Sigma(A_1 \otimes A_2 \otimes \cdots \otimes A_q) - \Sigma b\|_p$ (via convex optimization methods, e.g., [BCLL18])
  return $\widehat{x}$
end procedure

will show that by restricting the regression problem to the sampled rows, we can obtain our desired $(1 \pm \epsilon)$-approximate solution efficiently.

Our main theorem for this section is stated below. A full proof of the theorem can be found in the supplementary, namely, Section 26.7.

Theorem 26.3.1 (Kronecker product ℓ_2 regression)**.** *Let $D \in \mathbb{R}^{n \times n}$ be the diagonal row sampling matrix generated via Proposition 26.7.4, with $m = \Theta(1/(\delta\epsilon^2))$ non-zero entries, and let $A = \otimes_{i=1}^{q} A_i$, where $A_i \in \mathbb{R}^{n_i \times d_i}$, and $b \in \mathbb{R}^n$, where $n = \prod_{i=1}^{q} n_i$ and $d = \prod_{i=1}^{q} d_i$. Then let $\widehat{x} = \arg\min_{x \in \mathbb{R}^d} \|DAx - Db\|_2$, and let $x^* = \arg\min_{x' \in \mathbb{R}^d} \|Ax - b\|_2$. Then with probability $1 - \delta$, we have*

$$\|A\widehat{x} - b\|_2 \leq (1 + \epsilon)\|Ax^* - b\|_2.$$

Moreover, the total running time required to compute $\widehat{x}$ is $\widetilde{O}(\sum_{i=1}^{q} \mathrm{nnz}(A_i) + (dq/(\delta\epsilon))^{O(1)})$.

26.3.1 Kronecker Product ℓ_p Regression

We now consider ℓ_p regression for $1 \leq p < 2$. Our algorithm is stated formally in Algorithm 26.2. Below is our main theorem, which demonstrates that Algorithm 26.2 approximately solves the Kronecker ℓ_p regression problem with input sparsity running time.

Theorem 26.3.2 (Main result, ℓ_p $(1+\epsilon)$-approximate regression)**.** *Fix $1 \leq p < 2$. Then for any constant $q = O(1)$, given matrices $A_1, A_2, \cdots, A_q$, where $A_i \in \mathbb{R}^{n_i \times d_i}$, let $n = \prod_{i=1}^{q} n_i$, $d = \prod_{i=1}^{q} d_i$. Let $\widehat{x} \in \mathbb{R}^d$ be the output of Algorithm 26.2. Then*

$$\|(A_1 \otimes A_2 \otimes \cdots \otimes A_q)\widehat{x} - b\|_p \leq (1 + \epsilon) \min_{x \in \mathbb{R}^n} \|(A_1 \otimes A_2 \otimes \cdots \otimes A_q)x - b\|_p$$

holds with probability at least $1-\delta$. In addition, our algorithm takes $\widetilde{O}\left(\left(\sum_{i=1}^{q} \mathrm{nnz}(A_i) + \mathrm{nnz}(b) + (d/\epsilon)^{O(1)}\right)\right.$ time to output $\widehat{x} \in \mathbb{R}^d$.

We give a complete proof of the above theorem in the supplementary material, namely, in Section 26.8. Our high level approach follows that of [DDH+09]. Namely, we first obtain

a vector x' which is an $O(1)$-approximate solution to the optimal solution. This is done by first constructing (implicitly) a matrix $U \in \mathbb{R}^{n \times d}$ that is a well-conditioned basis for the design matrix $A_1 \otimes \cdots \otimes A_q$. We then efficiently sample rows of U with probability proportional to their ℓ_p norm (which must be done without even explicitly computing most of U). We then use the results of [DDH+09] to demonstrate that solving the regression problem constrained to these sampled rows gives a solution $x' \in \mathbb{R}^d$ such that $\|(A_1 \otimes \cdots \otimes A_q)x' - b\|_p \leq 8 \min_{x \in \mathbb{R}^d} \|(A_1 \otimes \cdots \otimes A_q)x' - b\|_p$.

We define the *residual error* $\rho = (A_1 \otimes \cdots \otimes A_q)x' - b \in \mathbb{R}^n$ of x'. Our goal is to sample additional rows $i \in [n]$ with probability proportional to their residual error $|\rho_i|^p / \|\rho\|_p^p$, and solve the regression problem restricted to the sampled rows. However, we cannot afford to compute even a small fraction of the entries in ρ (even when b is dense, and certainly not when b is sparse). So to carry out this sampling efficiently, we design an involved, multi-part sketching and sampling routine (described in Section 26.8). This sampling technique is the main technical contribution of this section, and relies on a number of techniques, such as the Dyadic trick for quickly finding heavy hitters in the streaming literature, and a careful pre-processing step to avoid a poly(d)-blow up in the runtime. Given these samples, we can obtain the solution $\widehat{x}$ after solving the regression problem on the sampled rows, and the fact that this gives a $(1+\epsilon)$ approximate solution will follow from Theorem 6 of [DDH+09].

26.4 All-Pairs Regression

Given a matrix $A \in \mathbb{R}^{n \times d}$ and $b \in \mathbb{R}^n$, let $\bar{A} \in \mathbb{R}^{n^2 \times d}$ be the matrix such that $\bar{A}_{i+(j-1)n,*} = A_{i,*} - A_{j,*}$, and let $\bar{b} \in \mathbb{R}^{n^2}$ be defined by $\bar{b}_{i+(j-1)n} = b_i - b_j$. Thus, $\bar{A}$ consists of all pairwise differences of rows of A, and $\bar{b}$ consists of all pairwise differences of rows of b,.

The ℓ_p all pairs regression problem on the inputs A, b is to solve $\min_{x \in \mathbb{R}^d} \|\bar{A}x - \bar{b}\|_p$.

First note that this problem has a close connection to Kronecker product regression. Namely, the matrix $\bar{A}$ can be written $\bar{A} = A \otimes \mathbf{1}^n - \mathbf{1}^n \otimes A$, where $\mathbf{1}^n \in \mathbb{R}^n$ is the all 1's vector. Similarly, $\bar{b} = b \otimes \mathbf{1}^n - \mathbf{1}^n \otimes b$. For simplicity, we now drop the superscript and write $\mathbf{1} = \mathbf{1}^n$.

Our algorithm is given formally in Figure 26.3. We generate sparse p-stable sketches $S_1, S_2 \in \mathbb{R}^{k \times n}$, where $k = (d/(\epsilon\delta))^{O(1)}$. We compute $M = (S_1 \otimes S_2)(F \otimes \mathbf{1} - \mathbf{1} \otimes F) = S_1 F \otimes S_2 \mathbf{1} - S_1 \mathbf{1} \otimes S_2 F$, where $F = [A, b]$. We then take the QR decomposition $M = QR$. Finally, we sample rows of $(F \otimes \mathbf{1} - \mathbf{1} \otimes F)R^{-1}$ with probability proportional to their ℓ_p norms. This is done by an involved sampling procedure described in Lemma 26.4.2, which is similar to the sampling procedure used in the proof of Theorem 26.3.2. Finally, we solve the regression problem $\min_x \|\Pi(\bar{A}x - \bar{b})\|_p$, where Π is the diagonal row-sampling matrix constructed by the sampling procedure. We summarize the guarantee of our algorithm in the following theorem.

Theorem 26.4.1. *Given $A \in \mathbb{R}^{n \times d}$ and $b \in \mathbb{R}^n$, for $p \in [1, 2]$, let $\bar{A} = A \otimes \mathbf{1} - \mathbf{1} \otimes A \in \mathbb{R}^{n^2 \times d}$ and $\bar{b} = b \otimes \mathbf{1} - \mathbf{1} \otimes b \in \mathbb{R}^{n^2}$. Then there is an algorithm for that outputs $\widehat{x} \in \mathbb{R}^d$ such that with probability $1 - \delta$ we have $\|\bar{A}\widehat{x} - \bar{b}\|_p \leq (1 + \epsilon) \min_{x \in \mathbb{R}^d} \|\bar{A}x - \bar{b}\|_p$. The running time is $\widetilde{O}(\text{nnz}(A) + (d/(\epsilon\delta))^{O(1)})$.*

The theorem crucially utilizes our fast ℓ_p sampling routine, which is described in Figure 26.5 in the supplementary. A full discussion and proof of the lemma can be found in the supplementary material 26.9.1.

Algorithm 26.3 Our All-Pairs Regression Algorithm

procedure ALL-PAIRS REGRESSION(A, b)
  $F = [A, b] \in \mathbb{R}^{n \times d+1}$. $r \leftarrow \text{poly}(d/\epsilon)$
  Generate $S_1, S_2 \in \mathbb{R}^{k \times n}$ sparse p-stable transforms for $k = \text{poly}(d/(\epsilon\delta))$.
  Sketch $(S_1 \otimes S_2)(F \otimes \mathbf{1} - \mathbf{1} \otimes F)$.
  Compute QR decomposition: $(S_1 \otimes S_2)(F \otimes \mathbf{1} - \mathbf{1} \otimes F) = QR$.
  Let $M = (F \otimes \mathbf{1} - \mathbf{1} \otimes F)R^{-1}$, and $\sigma_i = \|M_{i,*}\|_p^p / \|M\|_p^p$.
  Obtain row sampling diagonal matrix $\Pi \in \mathbb{R}^{n \times n}$ such that $\Pi_{i,i} = 1/\widetilde{q}_i^{1/p}$ independently with probability $q_i \geq \min\{1, r\sigma_i\}$, where $\widetilde{q}_i = (1 \pm \epsilon^2)q_i$. ▷ Lemma 26.4.2
  return $\widehat{x}$, where $\widehat{x} = \arg\min_{x \in \mathbb{R}^d} \|\Pi(\bar{A}x - \bar{b})\|_p$.
end procedure

Lemma 26.4.2 (Fast ℓ_p sampling)**.** *Given $R \in \mathbb{R}^{d+1 \times d+1}$ and $F = [A, b] \in \mathbb{R}^{n \times d+1}$, there is an algorithm that, with probability $1 - n^{-c}$ for any constant c, produces a diagonal matrix $\Pi \in \mathbb{R}^{n^2 \times n^2}$ such that $\Pi_{i,i} = 1/\widetilde{q}_i^{1/p}$ with probability $q_i \geq \min\{1, r\|M_{i,*}\|_p^p / \|M\|_p^p\}$ and $\Pi_{i,i} = 0$ otherwise, where $r = \text{poly}(d/\epsilon)$ and $M = (F \otimes \mathbf{1} - \mathbf{1} \otimes F)R^{-1}$, and $\widetilde{q}_i = (1 \pm \epsilon^2)q_i$ for all $i \in [n^2]$. The total time required is $\widetilde{O}(\text{nnz}\, A + \text{poly}(d/\epsilon))$.*

26.5 Low Rank Approximation of Kronecker Product Matrices

We now consider low rank approximation of Kronecker product matrices. Given q matrices $A_1, A_2, \ldots, A_q$, where $A_i \in \mathbb{R}^{n_i \times d_i}$, the goal is to output a rank-k matrix $B \in \mathbb{R}^{n \times d}$, where $n = \prod_{i=1}^q n_i$ and $d = \prod_{i=1}^q d_i$, such that $\|B - A\|_F \leq (1 + \epsilon)\,\text{OPT}_k$, where $\text{OPT}_k = \min_{\texttt{rank}-k\ A'} \|A' - A\|_F$, and $A = \otimes_{i=1}^q A_i$. Our approach employs the Count-Sketch distribution of matrices [CW13, Woo14b]. A count-sketch matrix S is generated as follows. Each column of S contains exactly one non-zero entry. The non-zero entry is placed in a uniformly random row, and the value of the non-zero entry is either 1 or -1 chosen uniformly

at random.

Our algorithm is as follows. We sample q independent Count-Sketch matrices $S_1, \dots S_q$, with $S_i \in \mathbb{R}^{k_i \times n_i}$, where $k_1 = \cdots = k_q = \Theta(qk^2/\epsilon^2)$. We then compute $M = (\otimes_{i=1}^{q} S_i)A$, and let $U \in \mathbb{R}^{k \times d}$ be the top k right singular vectors of M. Finally, we output $B = AU^\top U$ in factored form (as $q+1$ separate matrices, $A_1, A_2, \dots, A_q, U$), as the desired rank-k approximation to A. The following theorem demosntrates the correctness of this algorithm. A full proof can be found in Section 26.10.

Theorem 26.5.1. *For any constant $q \geq 2$, there is an algorithm which runs in time $O(\sum_{i=1}^{q} \operatorname{nnz}(A_i) + d\operatorname{poly}(k/\epsilon))$ and outputs a rank k-matrix B in factored form such that $\|B - A\|_F \leq (1+\epsilon)\operatorname{OPT}_k$ with probability 9/10.* [4]

26.6 Numerical Simulations

In our numerical simulations, we compare our algorithms to two baselines: (1) brute force, i.e., directly solving regression without sketching, and (2) the methods based sketching developed in [DSSW18]. All methods were implemented in Matlab on a Linux machine. We remark that in our implementation, we simplified some of the steps of our theoretical algorithm, such as the residual sampling algorithm (Alg. 26.4). We found that in practice, even with these simplifications, our algorithms already demonstrated substantial improvements over prior work.

Following the experimental setup in [DSSW18], we generate matrices $A_1 \in \mathbb{R}^{300 \times 15}$,

[4] To amplify the probability, we can sketch A and $AU^\top U$ with a sparse JL matrix (e.g., Lemma 26.10.1 with $k_i = \Theta(qk^2/(\delta\epsilon^2))$ for each i) in input sparsity time to estimate the cost of a given solution. We can then repeat $\log(1/\delta)$ times and take the minimum to get failure probability $1 - \delta$.

$A_2 \in \mathbb{R}^{300\times 15}$, and $b \in \mathbb{R}^{300^2}$, such that all entries of A_1, A_2, b are sampled i.i.d. from a normal distribution. Note that $A_1 \otimes A_2 \in \mathbb{R}^{90000\times 225}$. We define T_{bf} to be the time of the brute force algorithm, T_{old} to be the time of the algorithms from [DSSW18], and T_{ours} to be the time of our algorithms. We are interested in the time ratio with respect to the brute force algorithm and the algorithms from [DSSW18], defined as, $r_t = T_{\text{ours}}/T_{\text{bf}}$, and $r'_t = T_{\text{ours}}/T_{\text{old}}$. The goal is to show that our methods are significantly faster than both baselines, i.e., both r_t and r'_t are significantly less than 1.

We are also interested in the quality of the solutions computed from our algorithms, compared to the brute force method and the method from [DSSW18]. Denote the solution from our method as x_{our}, the solution from the brute force method as x_{bf}, and the solution from the method in [DSSW18] as x_{old}. We define the relative residual percentage $r_e$and r'_e to be:

$$r_e = 100\frac{|\|\mathcal{A}x_{\text{ours}} - b\| - \|\mathcal{A}x_{\text{bf}} - b\||}{\|\mathcal{A}x_{\text{bf}} - b\|}, \quad r'_e = 100\frac{|\|\mathcal{A}x_{\text{old}} - b\| - \|\mathcal{A}x_{\text{bf}} - b\||}{\|\mathcal{A}x_{\text{bf}} - b\|}$$

Where $\mathcal{A} = A_1 \otimes A_2$. The goal is to show that r_e is close zero, i.e., our approximate solution is comparable to the optimal solution in terms of minimizing the error $\|\mathcal{A}x - b\|$.

Throughout the simulations, we use a moderate input matrix size so that we can accommodate the brute force algorithm and to compare to the exact solution. We consider varying values of m, where M denotes the size of the sketch (number of rows) used in either the algorithms of [DSSW18] or the algorithms in this paper. We also include a column m/n in the table, which is the ratio between the size of the sketch and the original matrix $A_1 \otimes A_2$. Note in this case that $n = 90000$.

Table 26.1: Results for ℓ_2 and ℓ_1-regression with respect to different sketch sizes m.

	m	m/n	r_e	r'_e	r_t	r'_t
ℓ_2	8100	.09	2.48%	1.51%	0.05	0.22
	12100	.13	1.55%	0.98%	0.06	0.24
	16129	.18	1.20%	0.71%	0.07	0.08
ℓ_1	2000	.02	7.72%	9.10%	0.02	0.59
	4000	.04	4.26%	4.00%	0.03	0.75
	8000	.09	1.85%	1.6%	0.07	0.83
	12000	.13	1.29%	0.99%	0.09	0.79
	16000	.18	1.01%	0.70%	0.14	0.90

Simulation Results for ℓ_2 We first compare our algorithm, Alg. 26.1, to baselines under the ℓ_2 norm. In our implementation, $\min_x \|Ax - b\|_2$ is solved by Matlab backslash $A\backslash b$. Table 26.1 summarizes the comparison between our approach and the two baselines. The numbers are averaged over 5 random trials. First of all, we notice that our method in general provides slightly less accurate solutions than the method in [DSSW18], i.e., $r_e > r'_e$ in this case. However, comparing to the brute force algorithm, our method still generates relatively accurate solutions, especially when m is large, e.g., the relative residual percentage w.r.t. the optimal solution is around 1% when $m \approx 16000$. On the other hand, as suggested by our theoretical improvements for ℓ_2, our method is significantly faster than the method from [DSSW18], consistently across all sketch sizes m. Note that when $m \approx 16000$, our method is around 10 times faster than the method in [DSSW18]. For small m, our approach is around 5 times faster than the method in [DSSW18].

Simulation Results for ℓ_1 We compare our algorithm, Alg. 26.2, to two baselines under the ℓ_1-norm. The first is a brute-force solution, and the second is the algorithm for [DSSW18].

For $\min_x \|Ax - b\|_1$, the brute for solution is obtained via a Linear Programming solver in Gurobi [GO16]. Table 26.1 summarizes the comparison of our approach to the two baselines under the ℓ_1-norm. The statistics are averaged over 5 random trials. Compared to the Brute Force algorithm, our method is consistently around 10 times faster, while in general we have relative residual percentage around 1%. Compared to the method from [DSSW18], our approach is consistently faster (around 1.3 times faster). Note our method has slightly higher accuracy than the one from [DSSW18] when the sketch size is small, but slightly worse accuracy when the sketch size increases.

26.7 Missing Proofs from Section 26.3

In this section, we prove correctness of our ℓ_2 Kronecker product regression algorithm. Specifically, we prove Theorem 26.3.1. To prove correctness, we need to establish several facts about the leverage scores of a Kronecker product.

Proposition 26.7.1. *Let $U_i \in \mathbb{R}^{n_i \times d_i}$ be an orthonormal basis for $A_i \in \mathbb{R}^{n_i \times d_i}$. Then $U = \otimes_{i=1}^q U_i$ is an orthonormal basis for $A = \otimes_{i=1}^q A_i$.*

Proof. Note that the column norm of each column of U is the product of column norms of the U_i's, which are all 1. Thus U has unit norm columns. It suffices then to show that all the singular values of U are 1 or -1, but this follows from the fact that the singular values of U are the product of singular values of the U_i's, which completes the proof. □

Corollary 26.7.2. *Let $A = \otimes_{i=1}^q A_i$, where $A_i \in \mathbb{R}^{n_i \times d_i}$. Fix any $\vec{i} = (i_1, \ldots, i_q) \in [n_1] \times [n_2] \times \cdots \times [n_q]$, and let $\vec{i}$ index into a row of A in the natural way. Then the $\vec{i}$-th leverage score of A is equal to $\prod_{j=1}^q \sigma_{i_j}(A_j)$, where $\sigma_t(B)$ is the t-th leverage score of a matrix B.*

Proof. Note $U = \otimes_{i=1}^{q} U_i$ is an orthonormal basis for $A = \otimes_{i=1}^{q} A_i$ by the prior Proposition. Now if $U_{\vec{i},*}$ is the $\vec{i}$-th row of U, then by fundamental properties of Kronecker products [VL00], we have $\|U_{\vec{i},*}\|_2 = \prod_{j=1}^{q} \|(U_j)_{i_j,*}\|_2$, which completes the proof. Note here that we used the fact that leverage scores are independent of the choice of orthonormal basis [Woo14b]. □

Proposition 26.7.3 (Theorem 29 of [CW13])**.** *Given a matrix $A \in \mathbb{R}^{n \times d}$, let $\sigma \in \mathbb{R}^n$ be the ℓ_2 leverage scores of A (see definition 26.2.3). Then there is an algorithm which computes values $\widetilde{\sigma}_1, \widetilde{\sigma}_2, \ldots, \widetilde{\sigma}_n$ such that $\widetilde{\sigma}_i = (1 \pm \epsilon)\sigma_i$ simultaneously for all $i \in [n]$ with probability $1 - 1/n^c$ for any constant $c \geq 1$. The runtime is $\widetilde{O}(\mathrm{nnz}(A) + \mathrm{poly}(d/\epsilon))$.*

Proposition 26.7.4. *Given $A = \otimes_{i=1}^{q} A_i$, where $A_i \in \mathbb{R}^{n_i \times d_i}$, there is an algorithm which, with probability $1 - 1/n^c$ for any constant $c \geq 1$, outputs a diagonal matrix $D \in \mathbb{R}^{n \times n}$ with m non-zeros entries, such that $D_{i,i} = 1/(m\widetilde{\sigma}_i)$ is non-zero with probability $\widetilde{\sigma}_i \in (1 \pm 1/10)\sigma_i(A)$. The time required is $\widetilde{O}(\sum_{i=1}^{q} \mathrm{nnz}(A_i) + \mathrm{poly}(dq/\epsilon) + mq)$.*

Proof. By Proposition 26.7.3, we can compute approximate leverage scores of each A_i up to error $\Theta(1/q)$ in time $\widetilde{O}(\mathrm{nnz}(A_i) + \mathrm{poly}(d/\epsilon))$ with high probability. To sample a leverage score from A, it suffices to sample one leverage score from each of the A_i's by Corollary 26.7.2. The probability that a given row $\vec{i} = (i_1, \ldots, i_q) \in [n_1] \times [n_2] \times \cdots \times [n_q]$ of A is chosen is $\prod_{j=1}^{q} \widetilde{\sigma}(A_j)_{i_j} = (1 \pm \Theta(1/q))^q \sigma_{\vec{i}}(A) = (1 \pm 1/10)\sigma_{\vec{i}}(A)$ as needed. Obtaining a sample takes $\widetilde{O}(1)$ time per A_i (since a random number needs to be generated to $O(\log(n))$-bits of precision in expectation and with high probability to obtain this sample), thus $O(q)$ time overall, so repeating the sampling M times gives the desired additive mq runtime. □

The $q = 1$ version of the following result can be found in [CW13, SWZ19b].

Proposition 26.7.5. *Let $D \in \mathbb{R}^{n \times n}$ be the diagonal row sampling matrix generated via Proposition 26.7.4, with $m = \Theta(1/(\delta\epsilon^2))$ non-zero entries. Let $A = \otimes_{i=1}^{q} A_i$ as above, and let $U \in \mathbb{R}^{n \times r}$ be an orthonormal basis for the column span of A, where $r = \mathrm{rank}(A)$. Then for any matrix B with n rows, we have*

$$\Pr\left[\|U^\top D^\top DB - U^\top B\|_F \leq \epsilon \|U\|_F \|B\|_F\right] \geq 1 - \delta$$

Proof. By definition of leverage scores and Proposition 26.7.4, D is a matrix which sample each row $U_{i,*}$ of U with probability at least $(9/10)\|U_{i,*}\|_2/\|U\|_F$. Taking the average of m such rows, we obtain the approximate matrix product result with error $O(1/\sqrt{\delta m})$ with probability $1 - \delta$ by Theorem 2.1 of [KV17]. □

We our now ready to prove the main theorem of this section, Theorem 26.3.1

Theorem 26.3.1(Kronecker product ℓ_2 regression) *Let $D \in \mathbb{R}^{n \times n}$ be the diagonal row sampling matrix generated via Proposition 26.7.4, with $m = \Theta(1/(\delta\epsilon^2))$ non-zero entries, and let $A = \otimes_{i=1}^{q} A_i$, where $A_i \in \mathbb{R}^{n_i \times d_i}$, and $b \in \mathbb{R}^n$, where $n = \prod_{i=1}^{q} n_i$ and $d = \prod_{i=1}^{q} d_i$. Then we have let $\widehat{x} = \arg\min_{x \in \mathbb{R}^d} \|DAx - Db\|_2$, and let $x^* = \arg\min_{x' \in \mathbb{R}^d} \|Ax - b\|_2$. Then with probability $1 - \delta$, we have*

$$\|A\widehat{x} - b\|_2 \leq (1 + \epsilon)\|Ax^* - b\|_2$$

Moreover, the total runtime requires to compute $\widehat{x}$ is

$$\widetilde{O}\left(\sum_{i=1}^{q} \mathrm{nnz}(A_i) + (dq/(\delta\epsilon))^{O(1)}\right).$$

Proof. Let U be an orthonormal basis for the column span of A. By Lemma 3.3 of [CW09], we have $\|A(\widehat{x}-x^*)\|_2 \leq 2\sqrt{\epsilon}\|Ax^*-b\|_2$. Note that while Lemma 3.3 of [CW09] uses a different sketching matrix D than us, the only property required for the proof of Lemma 3.3 is that $|U^\top D^\top DB - U^\top B\|_F \leq \sqrt{\epsilon/d}\|A\|_F\|B\|_F$ with probability at least $1-\delta$ for any fixed matrix B, which we obtain by Proposition 26.7.5 by having $O(d/(\delta\epsilon^2))$ non-zeros on the diagonal of D). By the normal equations, we have $A^\top(Ax^*-b)=0$, thus $\langle A(\widehat{x}-x^*),(Ax^*-b)\rangle = 0$, and so by the Pythagorean theorem we have

$$\|A\widehat{x}-b\|_2^2 = \|Ax^*-b\|_2^2 + \|A(\widehat{x}-x^*)\|_2^2 \leq (1+4\epsilon)\|Ax^*-b\|_2^2$$

Which completes the proof after rescaling of ϵ. The runtime required to obtain the matrix D is $\widetilde{O}(\sum_{i=1}^q \text{nnz}(A_i) + \text{poly}(dq/\epsilon))$ by Proposition 26.7.4, where we set D to have $m = \Theta(d/(\delta\epsilon^2))$ non-zero entries on the diagonal. Once D is obtained, one can compute $D(A+b)$ in time $O(md)$, thus the required time is $O(\delta^{-1}(d/\epsilon)^2)$. Finally, computing $\widehat{x}$ once DA, Db are computed requires a single pseudo-inverse computation, which can be carried out in $O(\delta^{-1}d^3/\epsilon^2)$ time (since DA now has only $O(\delta^{-1}(d/\epsilon)^2)$ rows).

□

26.8 Missing Proofs from Section 26.3.1

We now give a complete proof of Theorem 26.3.2. Our high level approach follows that of [DDH+09]. Namely, we first obtain a vector x' which is a $O(1)$ approximate solution to the optimal, and then use the *residual error* $\rho \in \mathbb{R}^d$ of x' to refine x' to a $(1\pm\epsilon)$ approximation $\widehat{x}$. The fact that x' is a constant factor approximation follows from our Lemma 26.8.4. Given x', by Lemma 26.8.7 we can efficiently compute the matrix Σ which samples from

the coordinates of the residual error $\rho = (A_1 \otimes \cdots \otimes A_q)x' - b$ in the desired runtime. The sampling lemma is the main technical lemma, and requires a careful multi-part sketching and sampling routine. Given this Σ, the fact that $\widehat{x}$ is a $(1+\epsilon)$ approximate solution follows directly from Theorem 6 of [DDH+09]. Our main theorem and its proof is stated below. The proof will utilize the lemmas and sampling algorithm developed in the secitons which follow.

Theorem 26.3.2 (Main result, ℓ_p, $1+\epsilon$-approximation)**.** *Fix $1 \leq p < 2$. Then for any constant $q = O(1)$, given matrices $A_1, A_2, \cdots, A_q$, where $A_i \in \mathbb{R}^{n_i \times d_i}$, let $n = \prod_{i=1}^{q} n_i$, $d = \prod_{i=1}^{q} d_i$. Let $\widehat{x} \in \mathbb{R}^d$ be the output of Algorithm 26.2. Then*

$$\|(A_1 \otimes A_2 \otimes \cdots \otimes A_q)\widehat{x} - b\|_p \leq (1+\epsilon) \min_{x \in \mathbb{R}^n} \|(A_1 \otimes A_2 \otimes \cdots \otimes A_q)x - b\|_p$$

holds with probability at least $1 - \delta$. In addition, our algorithm takes

$$\widetilde{O}\left(\left(\sum_{i=1}^{q} \operatorname{nnz}(A_i) + \operatorname{nnz}(b) + (d/\epsilon)^{O(1)}\right) \log(1/\delta)\right)$$

time to output $\widehat{x} \in \mathbb{R}^d$.

Proof. By Lemma 26.8.4, the output x' in line 16 of algorithm 26.3.1 is an 8 approximation of the optimal solution, and x' is obtained in time $\widetilde{O}(\sum_{i=1}^{q} \operatorname{nnz}(A_i) + (dq/\epsilon)^{O(1)})$. We then obtain the residual error $\rho = (A_1 \otimes \cdots \otimes A_q)x' - b$ (implicitly). By Theorem 6 of [DDH+09], if we let $\Sigma \in \mathbb{R}^{n \times n}$ be a row sampling matrix where $\Sigma_{i,i} = 1/\alpha_i^{1/p}$ with probability $\alpha_i = \min\{1, \max\{q_i, r_2 \frac{|\rho_i|^p}{\|\rho\|_p^p}\}$, where q_i is the row sampling probability used in the sketch Π from which x' was obtained, and$r_2 = O(d^3/\epsilon^2 \log(1/\epsilon))$, then the solution to $\min_x \|\Sigma(A_1 \otimes \cdots \otimes A_q)x - \Sigma b\|_p$ will be a $(1+\epsilon)$ approximately optimal solution. By Lemma 26.8.7, we can obtain such a matrix Σ in time $\widetilde{O}(\sum_{i=1}^{q} \operatorname{nnz}(A_i) + q \operatorname{nnz}(b) + (d \log(n)/(\epsilon\delta)^{O(q^2)})$, which completes the proof of correctness. Finally, note that we can solve the sketched regression problem

$\min_x \|\Sigma(A_1 \otimes \cdots \otimes A_q)x - \Sigma b\|_p$ which has $O((d\log(n)/\epsilon)^{O(q^2)}(1/\delta))$ constraints and d variables in time $O((d\log(n)/\epsilon)^{O(q^2)}(1/\delta))$ using linear programming for $p = 1$ (see [CLS19] for the state of the art linear program solver), or more generally interior point methods for convex programming for $p > 1$ (see [BCLL18] for the state of the art ℓ_p solver).

Now to boost the failure probability from a $O(1/\delta)$ to $\log(1/\delta)$ dependency, we do the following. We run the above algorithm with $\delta = 1/10$, so that our output $\widehat{x} \in \mathbb{R}^d$ is a $(1+\epsilon)$ approximation with probability $9/10$. Now note that we actually have an $(1+\epsilon)$ estimate of the cost $\|(A_1 \otimes A_2 \otimes \cdots \otimes A_q)\widehat{x} - b\|_p$ of the solution $\widehat{x}$, which is simply given by $\|\Sigma(A_1 \otimes A_2 \otimes \cdots \otimes A_q)\widehat{x} - \Sigma b\|_p$ where Σ is the sampling matrix used to compute $\widehat{x}$. Thus we can simply repeat the above process $O(\log(1/\delta))$ times, and take the solution with the minimal cost overall. □

We start by defining a tensor operation which will be useful for our analysis.

Definition 26.8.1 ($((\cdot,\ldots,\cdot),\cdot)$ operator for tensors and matrices)**.** Given tensor $A \in \mathbb{R}^{d_1 \times d_2 \times \cdots \times d_q}$ and matrices $B_i \in \mathbb{R}^{n_i \times d_i}$ for $i \in [q]$, we define the tensor $((B_1, B_2, \ldots, B_q), A) \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_q}$:

$$((B_1, B_2, \ldots, B_q), A)_{i_1,\ldots,i_q} = \sum_{i'_1=1}^{d_1} \sum_{i'_2=1}^{d_2} \cdots \sum_{i'_q=1}^{d_q} A_{i'_1,i'_2,\ldots,i'_q} \prod_{\ell=1}^{q} (B_\ell)_{i_\ell,i'_\ell}$$

Observe for the case of $q = 2$, we just have $((B_1, B_2), A) = B_1 A B_2^\top \in \mathbb{R}^{n_1 \times n_2}$.

Using the above notation, we first prove a result about reshaping tensors.

Lemma 26.8.1 (Reshaping)**.** *Given matrices $A_1, A_2, \cdots, A_q \in \mathbb{R}^{n_i \times d_i}$ and a tensor $B \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_q}$, let $n = \prod_{i=1}^q n_i$ and let $d = \prod_{i=1}^d d_i$. Let b denote the vectorization of B.*

For any tensor $X \in \mathbb{R}^{d_1 \times d_2 \times \cdots \times d_q}$, we have $\|((A_1, A_2, \cdots, A_q), X) - B\|_\xi$ is equal to $\|(A_1 \otimes A_2 \otimes \cdots \otimes A_q)x - b\|_\xi$ where ξ is any entry-wise norm (such as an ℓ_p-norm) and x is the vectorization of X. See Definition 26.8.1 of the $((\cdot, \ldots, \cdot), \cdot)$ tensor operator.

Observe, for the case of $q = 2$, this is equivalent to the statement that $\|A_1 X A_2^\top - B\|_\xi = \|(A_1 \otimes A_2)x - b\|_\xi$.

Proof. For the pair $x \in \mathbb{R}^d$, $X \in \mathbb{R}^{d_1 \times d_2 \times \cdots \times d_q}$, the connection is the following: $\forall i_1 \in [d_1], \ldots, i_q \in [d_q]$,

$$x_{i_1 + \sum_{l=2}^{q} (i_l - 1) \cdot \prod_{t=1}^{l-1} d_t} = X_{i_1, \cdots, i_q}.$$

Similarly, for $b \in \mathbb{R}^n$, $B \in \mathbb{R}^{n_1 \times n_2 \times \cdots \times n_q}$, for any $j_1, \in [n_1], \ldots, j_q \in [n_q]$,

$$b_{j_1 + \sum_{l=2}^{q} (j_l - 1) \cdot \prod_{t=1}^{l-1} n_t} = B_{j_1, j_2, \cdots, j_q}.$$

For simplicity, for any $(i_1, \ldots, i_q) \in [d_1] \times \cdots \times [d_q]$ and $(j_1, \ldots, j_q) \in [n_1] \times \cdots \times [n_q]$ we define $\vec{i} = i_1 + \sum_{l=2}^{q} (i_l - 1) \cdot \prod_{t=1}^{l-1} d_t$ and similarly $\vec{j} = j_1 + \sum_{l=2}^{q} (j_l - 1) \cdot \prod_{t=1}^{l-1} n_t$. Then we can simplify the above relation and write $x_{\vec{i}} = X_{i_1, i_2, \cdots, i_q}$, and $b_{\vec{j}} = B_{j_1, j_2, \cdots, j_q}$.

For a matrix Z, let $Z_{i,*}$ denote the i-th row of Z. We consider the $\vec{j}$-th entry of $(A_1 \otimes A_2 \otimes \cdots \otimes A_q)x$,

$$\begin{aligned}
((A_1 \otimes A_2 \otimes \cdots \otimes A_q)x)_{\vec{j}} &= \left\langle (A_1 \otimes A_2 \otimes \cdots \otimes A_q)_{\vec{j},*} \cdot x \right\rangle \\
&= \sum_{i_1=1}^{d_1} \sum_{i_2=1}^{d_2} \cdots \sum_{i_q=1}^{d_q} \left(\prod_{l=1}^{q} (A_l)_{j_l, i_l} \right) \cdot x_{\vec{i}} \\
&= \sum_{i_1=1}^{d_1} \sum_{i_2=1}^{d_2} \cdots \sum_{i_q=1}^{d_q} \left(\prod_{l=1}^{q} (A_l)_{j_l, i_l} \right) \cdot X_{i_1, i_2, \cdots, i_q} \\
&= ((A_1, A_2, \cdots, A_q), X)_{j_1, \ldots, j_q}.
\end{aligned}$$

Where the last equality is by Definition (26.8.1). Since we also have $b_{\vec{j}} = B_{j_1,\ldots,j_q}$, this completes the proof of the Lemma. □

26.8.1 Sampling from an ℓ_p-Well-Conditioned Base

In this Section, we discuss the first half of Algorithm 26.2 which computes $x' \in \mathbb{R}^d$, which we will show is a $O(1)$-approximate solution to the optimal. First note that by Lemma 26.2.1 together with fact 26.2.2, we know that $A_i R_i^{-1}$ is an ℓ_p well conditioned basis for A_i (recall this means that $A_i R_i^{-1}$ is a (α, β, p) well conditioned basis for A, and $\beta/\alpha = d_i^{O(1)}$) with probability $1 - O(1/q)$, and we can then union bound over this occurring for all $i \in [q]$. Given this, we now prove that $(A_1 R_1^{-1} \otimes A_2 R_2^{-1} \otimes \cdots \otimes A_q R_q^{-1})$ is a well conditioned basis for $(A_1 \otimes A_2 \otimes \cdots \otimes A_q)$.

Lemma 26.8.2. *Let $A_i \in \mathbb{R}^{n_i \times d_i}$ and $R_i \in \mathbb{R}^{d_i \times d_i}$. Then if $A_i R_i^{-1}$ is a (α_i, β_i, p) well-conditioned basis for A_i for $i = 1, 2, \ldots, q$, we have for all $x \in \mathbb{R}^{d_1 \cdots d_q}$:*

$$\prod_{i=1}^{q} \alpha_i \|x\|_p \leq \|(A_1 R_1^{-1} \otimes A_2 R_2^{-1} \otimes \cdots \otimes A_q R_q^{-1})x\|_p \leq \prod_{i=1}^{q} \beta_i \|x\|_p$$

Proof. We first consider the case of $q = 2$. We would like to prove

$$\alpha_1 \alpha_2 \|x\|_p \leq \|(A_1 R_1^{-1} \otimes A_2 R_2^{-1})x\|_p \leq \beta_1 \beta_2 \|x\|_p,$$

First note, by the reshaping Lemma 26.8.1, this is equivalent to

$$\alpha_1 \alpha_2 \|X\|_p \leq \|A_1 R_1^{-1} X (R_2^{-1} A_2)^\top\|_p \leq \beta_1 \beta_2 \|X\|_p.$$

Where $X \in \mathbb{R}^{d_1 \times d_2}$ is the tensorization of x. We first prove one direction. Let $U_1 = A_1 R_1^{-1}$

and $U_2 = A_2 R_2^{-1}$. We have

$$\begin{aligned}\|U_1 X U_2^\top\|_p^p &= \sum_{i_2=1}^{n_2} \|U_1 (X U_2^\top)_{i_2}\|_p^p \\ &\leq \sum_{i_2=1}^{n_2} \beta_1^p \|(X U_2^\top)_{i_2}\|_p^p \\ &= \beta_1^p \|X U_2^\top\|_p^p \\ &\leq \beta_1^p \beta_2^p \|X\|_p^p,\end{aligned}$$

where the first step follows from rearranging, the second step follows from the well-conditioned property of U_1, the third step follows from rearranging again, the last step follows from the well-conditioned property of U_2. Similarly, we have

$$\begin{aligned}\|U_1 X U_2^\top\|_p^p &= \sum_{i_2=1}^{n_2} \|U_1 (X U_2^\top)_{i_2}\|_p^p \\ &\geq \sum_{i_2=1}^{n_2} \alpha_1^p \|(X U_2^\top)_{i_2}\|_p^p \\ &= \alpha_1^p \|X U_2^\top\|_p^p \\ &\geq \alpha_1^p \alpha_2^p \|X\|_p^p,\end{aligned}$$

where again the first step follows from rearranging, the second step follows from the well-conditioned property of U_1, the third step follows from rearranging again, the last step follows from the well-conditioned property of U_2.

In general, for arbitrary $q \geq 2$, similarly using our reshaping lemma, we have

$$\begin{aligned}\|(\otimes_{i=1}^q (A_i R_i^{-1}))x\|_p &\geq \prod_{i=1}^q \alpha_i \|x\|_p, \\ \|(\otimes_{i=1}^q (A_i R_i^{-1}))x\|_p &\leq \prod_{i=1}^q \beta_i \|x\|_p.\end{aligned}$$

□

Putting this together with fact 26.2.2, and noting $d = d_1 \cdots d_q$, we have

Corollary 26.8.3. *Let $A_i R_i^{-1}$ be as in algorithm 26.2. Then we have for all $x \in \mathbb{R}^{d_1 \cdots d_q}$:*

$$(1/d)^{O(1)} \|x\|_p \leq \|(A_1 R_1^{-1} \otimes \cdots \otimes A_q R_q^{-1})x\|_p \leq d^{O(1)} \|x\|_p,$$

In other words, $(A_1 R_1^{-1} \otimes \cdots \otimes A_q R_q^{-1})$ is a well conditioned ℓ_p basis for $(A_1 \otimes \cdots \otimes A_q)$

From this, we can obtain the following result.

Lemma 26.8.4. *Let $x' \in \mathbb{R}^d$ be the output of the $O(1)$-Approximate ℓ_p Regression Procedure in Algorithm 26.2. Then with probability $99/100$ we have*

$$\|(A_1 \otimes \cdots \otimes A_q)x' - b\|_p \leq 8 \min_x \|(A_1 \otimes \cdots \otimes A_q)x - b\|_p$$

Moreover, the time required to compute x' is $\widetilde{O}(\sum_{i=1}^q \operatorname{nnz}(A_i) + (dq/\epsilon)^{O(1)})$.

Proof. By Theorem 6 of [DDH+09], if we let Π be a diagonal row sampling matrix such that $\Pi_{i,i} = 1/q_i^{1/p}$ with probability $q_i \geq \min\{1, r_1 \frac{\|U_{i,*}\|_p^p}{\|U\|_p^p}\}$, where U is a ℓ_p well-conditioned basis for $(A_1 \otimes \cdots \otimes A_q)$ and $r_1 = O(d^3)$, then the solution x' to

$$\min_x \|\Pi((A_1 \otimes \cdots \otimes A_q)x - b\|$$

will be a 8-approximation. Note that we can solve the sketched regression problem $\min_x \|\Pi((A_1 \otimes \cdots \otimes A_q)x' - b\|$ which has $O(\text{poly}(d/\epsilon))$ constraints and d variables in time $\text{poly}(d/\epsilon)$ using linear programming for $p = 1$ (see [CLS19] for the state of the art linear program solver), or

more generally interior point methods for convex programming for $p > 1$ (see [BCLL18] for the state of the art ℓ_p solver).

Then by Corollary 26.8.3, we know that setting $U = (A_1 R_1^{-1} \otimes \cdots \otimes A_q R_q^{-1})$ suffices, so now we must sample rows of U. To do this, we must approximately compute the norms of the rows of U. Here, we use the fact that $\|\cdot\|_p^p$ norm of a row of $(A_1 R_1^{-1} \otimes \cdots \otimes A_q R_q^{-1})$ is the product of the row norms of the $A_i R_i^{-1}$ that correspond to that row. Thus it suffices to sample a row j_i from each of the $A_i R_i^{-1}$'s with probability at least $\min\{1, r_1 \|(A_i R_i^{-1})_{j_i,*}\|_p^p / \|A_i R_i^{-1}\|_p^p\}$ for each $i \in [q]$.

To do this, we must estimate all the row norms $\|(A_i R_i^{-1})_{j_i,*}\|_p^p$ to $(1 \pm 1/10)$ error. This is done in steps $7 - 10$ of Algorithm 26.2, which uses dense p-stable sketches $Z \in \mathbb{R}^{d \times \tau}$, and computes $(A_i R_i^{-1} Z)$, where $\tau = \Theta(\log(n))$. Note that computing $R_i^{-1} Z \in \mathbb{R}^{d \times \tau}$ requires $\widetilde{O}(d^2)$. Once computed, $A_i(R_i^{-1} Z)$ can be computed in $\widetilde{O}(\text{nnz}(A_i))$ time. We then take the median of the coordinates of $(A_i R_i^{-1} Z)$ (normalized by the median of the p-stable distribution $\mathcal{D}_p$, which can be efficiently approximated to $(1 \pm \epsilon)$ in $O(\text{poly}(1/\epsilon))$ time, see Appendix A.2 of [KNW10b] for details) as our estimates for the row norms. This is simply the Indyk median estimator [Ind06], and gives a $(1 \pm 1/10)$ estimate $a_{i,j}$ of all the row norms $\|(A_i R_i^{-1})_{j,*}\|_p^p$ with probability $1 - 1/\text{poly}(n)$. Then it follows by Theorem 6 of [DDH+09] that x' is a 8-approximation of the optimal solution with probability 99/100 (note that we amplified the probability by increasing the sketch sizes S_i by a constant factor), which completes the proof.

□

26.8.2 ℓ_p Sampling From the residual of a $O(1)$-factor approximation

By Lemma 26.8.4 in the prior section, we know that the x' first returned by the in algorithm 26.2 is a 8-approximation. We now demonstrate how we can use this $O(1)$ approximation to obtain a $(1+\epsilon)$ approximation. The approach is again to sample rows of $(A_1 \otimes \cdots \otimes A_q)$. But instead of sampling rows with the well-conditioned leverage scores q_i, we now sample the i-th row with probability $\alpha_i = \min\{1, \max\{q_i, r_2|\rho_i|^p/\|\rho\|_p^p\}\}$, where $\rho = (A_1 \otimes \cdots \otimes A_q)x' - b \in \mathbb{R}^n$ is the *residual error* of the $O(1)$-approximation x'. Thus we must now determine how to sample quickly from the residuals $|\rho_i|^p/\|\rho\|_p^p$. Our sampling algorithm will need a tool originally developed in the streaming literature.

Count-sketch for heavy hitters with the Dyadic Trick. We now introduce a sketch S which finds the ℓ_2 heavy hitters in a vector x efficently. This sketch S is known as count-sketch for heavy hitters with the Dyadic Trick. To build S we first stack $\Theta(\log(n))$ copies of the *count sketch matrix* $S^i \in \mathbb{R}^{k' \times n}$ [CW13]. The matrix S^i is constructed as follows. S^i has exactly one non-zero entry per column, which is placed in a uniformly random row, and given the value 1 or -1 uniformly at random. For S^i, let $h_i : [n] \to [k']$ be such that $h_i(t)$ is the row with the non-zero entry in the t-th column of S^i, and let $g_i : [n] \to \{1, -1\}$ be such that the value of that non-zero entry is $g_i(t)$. Note that the h_i, g_i can be implemented as 4-wise independent hash functions. Fix any $x \in \mathbb{R}^n$. Then given $S^1x, S^2x, \cdots, S^{\Theta(\log(n))}x$, we can estimate the value of any coordinate x_j by $\text{median}_{i \in \Theta\log(n)}\{g_i(j)(S^ix)_{h_i(j)}\}$.

It is well-known that this gives an estimate of x_j with additive error $\Theta(1/\sqrt{k'})\|x\|_2$ with probability $1 - 1/\operatorname{poly}(n)$ for all $j \in [n]$ [CCFC04]. However, naively, to find the heaviest coordinates in x, that is all coordinates x_j with $|x_j| \geq \Theta(1/\sqrt{k'})\|x\|_2$, one would

need to query $O(n)$ estimates. This is where the Dyadic trick comes in [CM04]. We repeat the above process $\Theta(\log(n))$ times, with matrices $S^{(i,j)}$, for $i, j \in \Theta(\log(n))$. Importantly, however, in $S^{(i,j)}$, for all $t, t' \in [n]$ such that the first j most significant bits in their binary identity representation are the same, we set $h_{(i,j)}(t) = h_{(i,j)}(t')$, effectively collapsing these identities to one. To find a heavy item, we can then query the values of the *two* identities from $S^{(1,1)}, S^{(2,1)}, \cdots, S^{(\Theta(\log(n)),1)}$, and recurse into all the portions which have size at least $\Theta(1/\sqrt{k'})\|x\|_2$. It is easy to see that we recurse into at most $O(k')$ such pieces in each of the $\Theta(\log(n))$ levels, and it takes $O(\log(n))$ time to query a single estimate, from which the desired runtime of $O(k' \log^2(n))$ is obtained. For a further improvement on size k of the overall sketched required to quickly compute Q, see [LNNT16]. We summarize this construction below in definition 26.8.2.

Definition 26.8.2 (Count-sketch for heavy hitters with Dyadic Trick [CCFC04, LNNT16])**.** There is a randomized sketch $S \in \mathbb{R}^{k \times n}$ with $k = O(\log^2(n)/\epsilon^2)$ such that, for a fixed vector $x \in \mathbb{R}^n$, given $Sx \in \mathbb{R}^k$, one can compute a set $Q \subset [n]$ with $|Q| = O(1/\epsilon^2)$ such that $\{i \in [n] \mid |x_i| \geq \epsilon \|x\|_2\} \subseteq Q$ with probability $1 - 1/\operatorname{poly}(n)$. Moreover, Sx can be computed in $O(\log^2(n) \operatorname{nnz}(x))$ time. Given Sx, the set Q can be computed in time $O(k)$.

We begin with some notation. For a vector $y \in \mathbb{R}^n$, where $n = n_1 \cdots n_q$, one can index any entry of y_i via $\vec{i} = (i_1, i_2, \cdots, i_q) \in [n_1] \times \cdots \times [n_q]$ via $i = i_1 + \sum_{j=2}^{q} (i_j - 1) \prod_{l=1}^{i_j - 1} n_l$. It will useful to index into such a vector y interchangably via a vector $y_{\vec{i}}$ and an index y_j with $j \in [n]$. For any set of subsets $T_i \subset [n_i]$, we can define $y_{T_1 \times \cdots T_q} \in \mathbb{R}^n$ as y restricted to the $\vec{i} \in T_1 \times \cdots \times T_q$. Here, by restricted, we mean the coordinates in y that are not in this set are set equal to 0. Similarly, for a $y \in \mathbb{R}^{n_i}$ and $S \subset [n_i]$, we can define y_S as y restricted

to the coordinates in S. Note that in Algorithm 26.4, $\mathbb{I}_n$ denotes the $n \times n$ identity matrix for any integer n. We first prove a proposition on the behavior of Kronecker products of p-stable vectors, which we will need in our analysis.

Proposition 26.8.5. *Let $Z_1, Z_2, \cdots, Z_q$ be independent vectors with entries drawn i.i.d. from the p-stable distribution, with $Z_i \in \mathbb{R}^{n_i}$. Now fix any $i \in [q]$, and any $x \in \mathbb{R}^n$, where $n = n_1 n_2 \cdots n_q$. Let $e_j \in \mathbb{R}^{n_i}$ be the j-th standard basis column vector for any $j \in [n_i]$. Let $\Gamma(i,j) = [n_1] \times [n_2] \times \cdots \times [n_{i-1}] \times \{j\} \times [n_{i+1}] \times \cdots \times [n_q]$. Define the random variable*

$$\mathcal{X}_{i,j}(x) = |(Z_1 \otimes Z_1 \otimes \cdots \otimes Z_{i-1} \otimes e_j^\top \otimes Z_{i+1} \otimes \cdots \otimes Z_q)x|^p.$$

Then for any $\lambda > 1$, with probability at least $1 - O(q/\lambda)$ we have

$$\|x_{\Gamma(i,j)}\|_p^p / \lambda^q \leq \mathcal{X}_{i,j}(x) \leq (\lambda \log(n))^q \|x_{\Gamma(i,j)}\|_p^p$$

Proof. First observe that we can reshape $y = x_\Gamma \in \mathbb{R}^m$ where $m = n/n_i$, and re-write this random variable as $\mathcal{X}_{i,j}(x) = |(Z_1 \otimes Z_2 \otimes \cdots \otimes Z_{q-1})y|^p$. By reshaping Lemma 26.8.1, we can write this as $|(Z_1 \otimes Z_2 \otimes \cdots \otimes Z_{q-2})Y Z_{q-1}^\top|^p$, where $Y \in \mathbb{R}^{m/n_{q-1} \times n_{q-1}}$. We first prove a claim. In the following, for a matrix A, let $\|A\|_p^p = \sum_{i,j} |A_{i,j}|^p$.

Claim 26.8.6. *Let Z be any p-stable vector and X a matrix. Then for any $\lambda > 1$, with probability $1 - O(1/\lambda)$, we have*

$$\lambda^{-1} \|X\|_p^p \leq \|XZ\|_p^p \leq \log(n)\lambda \|X\|_p^p.$$

Proof. By p-stability, each entry of $|(XZ)_i|^p$ is distributed as $|z_i|^p \|X_{i,*}\|_p^p$, where z_i is again p-stable (but the $z_i's$ are not independent). Now p-stables have tails that decay at the rate $\Theta(1/x^p)$ (see Chapter 1.5 of [Nol07]), thus $\Pr[|z_i|^p > x] = O(1/x)$ for any $x > 0$. We

can condition on the fact that $z_i < \lambda \cdot n^{10}$ for all i, which occurs with probability at least $1 - n^{-9}/\lambda$ by a union bound. Conditioned on this, we have $\mathbb{E}[|z_i|^p] = O(\log(n))$ (this can be seen by integrating over the truncated tail $O(1/x)$), and the upper bound then follows from a application of Markov's inequality.

For the lower bound Let Y_i be an indicator random variable indicating the event that $|z_i|^p < 2/\lambda$. Now p-stables are anti-concentrated, namely, their pdf is upper bounded by a constant everywhere. It follows that $\Pr[Y_i] < c/\lambda$ for some constant c. By Markov's inequality $\Pr[\sum_i Y_i \|X_{i,*}\|_p^p > \|X\|_p^p/2] < O(1/\lambda)$. Conditioned on this, the remaining $\|X\|_p^p/2$ of the ℓ_p mass shrinks by less than a $2/\lambda$ factor, thus $\|XZ\|_p^p > (\|X\|_p^p/2)(2/\lambda) = \|X\|_p^p/\lambda$ as needed. □

By the above claim, we have $\|Y\|_p/\lambda^{1/p} \leq \|YZ_{q-1}^\top\|_p \leq (\log(n)\lambda)^{1/p}\|Y\|_p$ with probability $1 - O(1/\lambda)$. Given this, we have $\mathcal{X}_{i,j}(x) = |(Z_1 \otimes Z_2 \otimes \cdots \otimes Z_{q-2})y'|^p$, where $\|Y\|_p/\lambda^{1/p} \leq \|y'\|_p \leq (\log(n)\lambda)^{1/p}\|Y\|_p$. We can inductively apply the above argument, each time getting a blow up of $(\log(n)\lambda)^{1/p}$ in the upper bound and $(1/\lambda)^p$ in the lower bound, and a failure probability of $(1/\lambda)$. Union bounding over all q steps of the induction, the proposition follows.

□

Lemma 26.8.7. *Fix any $r_2 \geq 1$, and suppose that $x' = \min_x \|\Pi(A_1 \otimes \cdots \otimes A_q)x - \Pi b\|_p$ and $\Pi \in \mathbb{R}^{n \times n}$ is a row sampling matrix such that $\Pi_{i,i} = 1/q_i^{1/p}$ with probability q_i. Define the residual error $\rho = (A_1 \otimes \cdots \otimes A_q)x' - b \in \mathbb{R}^n$. Then Algorithm 26.4, with probability $1 - \delta$, succeeds in outputting a row sampling matrix $\Sigma \in \mathbb{R}^{n \times n}$ such that $\Sigma_{i,i} = 1/\alpha_i^{1/p}$ with probability $\alpha_i = \min\{1, \max\{q_i, r_3|\rho_i|^p/\|\rho\|_p^p\}\}$ for some $r_3 \geq r_2$, and otherwise $\Sigma_{i,i} = 0$. The*

algorithm runs in time

$$\widetilde{O}\left(\sum_{i=1}^{q} \operatorname{nnz}(A_i) + q \operatorname{nnz}(b) + (r_2 \log(n)/\delta)^{O(q^2)}\right).$$

Proof. The algorithm is given formally in figure 26.4. We analyze the runtime and correctness here.

Proof of Correctness. The approach of the sampling algorithm is as follows. Recall that we can index into the coordinates of $\rho \in \mathbb{R}^n$ via $\vec{a} = (a_1, \ldots, a_q)$ where $a_i \in [n_i]$. We build the coordinates of $\vec{a}$ one by one. To sample a $\vec{a} \in \prod_{i=1}^{q} [n_i]$, we can first sample $a_1 \in [n_1]$ from the distribution $\Pr[a_1 = j] = \sum_{\vec{u}:u_1=j} |\rho_{\vec{u}}|^p / (\sum_{\vec{u}} |\rho_{\vec{u}}|^p)$. Once we fix a_1, we can sample a_2 from the conditional distribution distribution $\Pr[a_2 = j] = \sum_{\vec{u}:u_2=j,u_1=a_1} |\rho_{\vec{u}}|^p / (\sum_{\vec{u}:u_1=a_1} |\rho_{\vec{u}}|^p)$, and so on. For notation, given a vector $\vec{a} = (a_1, \ldots, a_{i-1})$, let $\Delta(\vec{a}) = \{\vec{u} \in [n_1] \times \cdots \times [n_q] \mid a_j = y_j \text{ for all } j = 1, 2, \ldots, i-1\}$. Then in general, when we have sampled $\vec{a} = (a_1, \ldots, a_{i-1})$ for some $i \leq q$, we need to sample $a_i \leftarrow j \in [n_k]$ with probability

$$\Pr[a_i = j] = \sum_{\vec{u} \in \Delta(\vec{a}):u_i=j} |\rho_{\vec{u}}|^p \Big/ \left(\sum_{\vec{u} \in \Delta(\vec{a})} |\rho_{\vec{u}}|^p\right).$$

We repeat this process to obtain the desired samples. Note that to sample efficiently, we will have to compute these aforementioned sampling probabilities approximately. Because of the error in approximating, instead of returning r_2 samples, we over-sample and return $r_3 = \Theta(r_2 \log^{q^2}(n))$ samples.

The first step is of the algorithm is to generate the p-stable vectors $Z^{i,j} \in \mathbb{R}^{n_i}$ for $i \in [q]$ and $j = 1, 2, \ldots, \Theta(\log(n))$. We can pre-compute and store $Z^{i,j} A_i$ for $i \in [q]$, which takes $\widetilde{O}(\sum_{i=1}^{q} \operatorname{nnz}(A_i))$ time. We set $w^j \leftarrow \left((\mathbb{I}_{n_1}) \otimes (\bigotimes_{k=2}^{q} Z^{k,j})\rho\right) \in \mathbb{R}^{n_1}$ and define $w \in \mathbb{R}^{n_1}$

by $w_l = \text{median}_{j\in[\tau]}\{|w_l^j|\}$ for $l \in [n_1]$. Observe that w_l^j is an estimate of $\sum_{\vec{u}:u_1=l} |\rho_{\vec{u}}|^p$. By Proposition 26.8.5, it is a $(c\log(n))^q$ approximation with probability at least $3/4$ for some constant c. Taking the median of $\Theta(\log(n))$ repetitions, we have that

$$c^{-q} \cdot \sum_{\vec{u}:u_1=l} |\rho_{\vec{u}}|^p \leq |w_l|^p \leq (c\log(n))^q \cdot \sum_{\vec{u}:u_1=l} |\rho_{\vec{u}}|^p$$

with probability $1 - 1/\operatorname{poly}(n)$, and we can then union bound over all such estimates every conducted over the course of the algorithm. We call the above estimate $|w_l|^p$ a $O((c\log(n))^q)$-error estimate of $\sum_{\vec{u}:u_1=l} |\rho_{\vec{u}}|^p$. Given this, we can correctly and independently sample the first coordinate of each of the $\Theta(r_3)$ samples. We now describe how to sample the i-th coordinate. So in general, suppose we have sampled $(a_1, ..., a_{i-1})$ so far, and we need to now sample $a_i \in [n_i]$ conditioned on $(a_1, ..., a_{i-1})$. We first consider

$$W^{i,k} = \left((\bigotimes_{k=1}^{i-1} e_{a_k}^\top) \otimes (\mathbb{I}_{n_i}) \otimes (\bigotimes_{k=i+1}^{q} Z^{k,j})\rho \right) \in \mathbb{R}^{n_i}$$

Note that the j-th coordinate $W_j^{i,k}$ for $W^{i,k}$ is an estimate of $\sum_{\vec{u}\in\Delta(\vec{a}):u_i=j} |\rho_{\vec{u}}|^p$. Again by By Proposition 26.8.5, with probability $1 - 1/\operatorname{poly}(n)$, we will have $|W_j^{i,k}|^p$ is a $O((c\log(n))^q)$-error estimate of $\sum_{\vec{u}\in\Delta(\vec{a}):u_i=j} |\rho_{\vec{u}}|^p$ or at least one $k \in [\tau]$. Our goal will now be to find all $j \in [n_i]$ such that $\sum_{\vec{u}\in\Delta(\vec{a}):u_i=j} |\rho_{\vec{u}}|^p \geq \Theta((c\log(n))^q/r_3^8) \sum_{\vec{u}\in\Delta(\vec{a})} |\rho_{\vec{u}}|^p$. We call such a j a *heavy hitter*.

Let $Q_i \subset [n_i]$ be the set of heavy hitters. To find all the heavy hitters, we use the count-sketch for heavy hitters with the Dyadic trick of definition 26.8.2. We construct this count-sketch of def 26.8.2 $S^i \in \mathbb{R}^{k'\times n_i}$ where $k' = O(\log^2(n)r_3^{16})$. We then compute $S^i W^{i,k}$, for $k = 1, 2, \ldots, \tau$, and obtain the set of heavy hitters $h \in H_{i,k} \subset [n_i]$ which satisfy $|W_j^{i,k}|^p \geq \Theta(1/r_3^8)\|W^{i,k}\|_p^p$. By the above discussion, we know that for each $j \in Q_i$, we

will have $|W_j^{i,k}|^p \geq \Theta(1/r_3^{16})\|W^{i,k}\|_p^p$ for at least one $k \in [\tau]$ with high probability. Thus $H_i = \cup_{k=1}^{\tau} H_{i,k} \supseteq Q_i$.

We now will decide to either sample a heavy hitter $\xi \in H_i$, or a non-heavy hitter $\xi \in [n_i] \setminus H_i$. By Proposition 26.8.5, we can compute a $O((c\log(n))^{-q})$-error estimate $\beta_i = \text{median}_{j\in\tau} \left|\left((\bigotimes_{k=1}^{i-1} e_{a_k}^\top) \otimes (\bigotimes_{k=i}^{q} Z^{k,j})\rho\right)\right|^p$ of $\sum_{\vec{u}\in\Delta(\vec{a})} |\rho_{\vec{u}}|^p$, meaning:

$$O(c^{-q}) \sum_{\vec{u}\in\Delta(\vec{a})} |\rho_{\vec{u}}|^p \leq \beta_i \leq O((c\log n)^q) \sum_{\vec{u}\in\Delta(\vec{a})} |\rho_{\vec{u}}|^p.$$

Again, by Proposition 26.8.5, we can compute a $O((c\log(n))^{-q})$-error estimate $\gamma_i \leftarrow \text{median}_{j\in[\tau]} \left((\bigotimes_{k=1}^{i-1} e_{a_k}^\top \right.$ of $\sum_{h\in[n_i]\setminus H_i} \sum_{\vec{u}\in\Delta(\vec{a}):u_i=j} |\rho_{\vec{u}}|^p$. It follows that

$$O(c^{-2q})\frac{\sum_{h\in[n_i]\setminus H_i} \sum_{\vec{u}\in\Delta(\vec{a}):u_i=j} |\rho_{\vec{u}}|^p}{\sum_{\vec{u}\in\Delta(\vec{a})} |\rho_{\vec{u}}|^p} \leq \frac{\gamma_i}{\beta_i} \leq O((c\log n)^{2q})\frac{\sum_{h\in[n_i]\setminus H_i} \sum_{\vec{u}\in\Delta(\vec{a}):u_i=j} |\rho_{\vec{u}}|^p}{\sum_{\vec{u}\in\Delta(\vec{a})} |\rho_{\vec{u}}|^p}$$

In other words, γ_i/β_i is a $O((c\log(n))^{2q})$-error approximation of the true probability that we should sample a non-heavy item. Thus with probability $1 - \gamma_i/\beta_i$, we choose to sample a heavy item.

To sample a heavy item, for each $\xi \in H_i$, by Proposition 26.8.5, we can compute an $O((c\log(n))^{-q})$-error estimate $\text{median}_{j\in\tau} \left|\left((\bigotimes_{k=1}^{i-1} e_{a_k}^\top) \otimes (e_\xi^\top) \otimes (\bigotimes_{k=i+1}^{q} Z^{k,j})\rho\right)\right|^p$ of $\sum_{\vec{u}\in\Delta(\vec{a}):u_i=\xi} |\rho_{\vec{u}}|^p$, meaning

$$\left(O(c^{-q}) \sum_{\vec{u}\in\Delta(\vec{a}):u_i=\xi} |\rho_{\vec{u}}|^p\right) \leq \text{median}_{j\in\tau} \left| \left((\bigotimes_{k=1}^{i-1} e_{a_k}^\top) \otimes (e_\xi^\top) \otimes (\bigotimes_{k=i+1}^{q} Z^{k,j})\rho \right) \right|^p$$
$$\leq \left(O((c\log n)^q) \sum_{\vec{u}\in\Delta(\vec{a}):u_i=\xi} |\rho_{\vec{u}}|^p\right)$$

Thus we can choose to sample a heavy item $\xi \in H_i$ from the distribution given by

$$\Pr\left[\text{sample } a_i \leftarrow \xi\right] = \frac{\text{median}_{j\in\tau} \left| \left((\bigotimes_{k=1}^{i-1} e_{a_k}^\top) \otimes (e_\xi^\top) \otimes (\bigotimes_{k=i+1}^{q} Z^{k,j})\rho \right) \right|^p}{\sum_{\xi'\in H_i} \text{median}_{j\in\tau} \left| \left((\bigotimes_{k=1}^{i-1} e_{a_k}^\top) \otimes (e_{\xi'}^\top) \otimes (\bigotimes_{k=i+1}^{q} Z^{k,j})\rho \right) \right|^p}$$

Which gives a $O((c\log(n))^{2q})$-error approximation to the correct sampling probability for a heavy item.

In the second case, with probability γ_i/β_i, we choose to not sample a heavy item. In this case, we must now sample a item from $[n_i] \setminus H_i$. To do this, we partition $[n_i]$ randomly into $\Omega_1, \ldots, \Omega_\eta$ for $\eta = 1/r_3^2$. Now there are two cases. First suppose that we have

$$\frac{\sum_{j\in[n_i]\setminus H_i} \sum_{\vec{u}\in\Delta(\vec{a}):u_i=j} |\rho_{\vec{u}}|^p}{\sum_{\vec{u}\in\Delta(\vec{a})} |\rho_{\vec{u}}|^p} \leq \Theta(1/r_3^3)$$

Now recall that γ_i/β_i was a $O((c\log(n))^{2q})$-error estimate of the ratio on the left hand side of the above equation, and γ_i/β_i was the probability with which we choose to sample a non-heavy hitter. Since we only repeat the sampling process r_3 times, the probability that we ever sample a non-heavy item in this case is at most $\Theta(q(c\log(n))^{2q}/r_3^2) < \Theta(q/r_3)$, taken over all possible repetitions of this sampling in the algorithm. Thus we can safely ignore this case, and condition on the fact that we never sample a non-heavy item in this

case. Otherwise, $\sum_{j\in[n_i]\setminus H_i}\sum_{\vec{u}\in\Delta(\vec{a}):u_i=j}|\rho_{\vec{u}}|^p > \Theta(1/r_3^3)\sum_{\vec{u}\in\Delta(\vec{a})}|\rho_{\vec{u}}|^p$, and it follows that $\sum_{\vec{u}\in\Delta(\vec{a}):u_i=j'}|\rho_{\vec{u}}|^p \leq \Theta(1/r_3^5\sum_{j\in[n_i]\setminus H_i})\sum_{\vec{u}\in\Delta(\vec{a}):u_i=j}|\rho_{\vec{u}}|^p$ for all $j'\in[n_i]\setminus H_i$, since we removed all $\Theta(1/r_3^8)$ heavy hitters from $[n_i]$ originally. Thus by Chernoff bounds, with high probability we have that $\sum_{j\in\Omega_i\setminus H_i}(\sum_{\vec{u}\in\Delta(\vec{a}):u_i=j}|\rho_{\vec{u}}|^p) = \Theta(1/\eta\sum_{j\in[n_i]\setminus H_i}\sum_{\vec{u}\in\Delta(\vec{a}):u_i=j}|\rho_{\vec{u}}|^p)$, which we can union bound over all repetitions.

Given this, by choosing $t\sim[\eta]$ uniformly at random, and then choosing $j\in\Omega_t\setminus H_i$ with probability proportional to its mass in $\Omega_t\setminus H_i$, we get a $\Theta(1)$ approximation of the true sampling probability. Since we do not know its exact mass, we instead sample from the distribution $\{\frac{\theta_j}{\sum_{j'\in\Omega_t\setminus H_i}\theta_{j'}}\}_{j\in\Omega_t\setminus H_i}$, where

$$\theta_j = \underset{l\in[\tau]}{\text{median}}\left(\left|(\bigotimes_{k=1}^{i-1}e_{a_k}^\top)\otimes(e_j^\top)\otimes(\bigotimes_{k=i+1}^{q}Z^{k,l})\rho\right|^p\right)$$

Again by Proposition 26.8.5, this gives a $O((c\log(n))^{2q})$-error approximation to the correct sampling probability. Note that at each step of sampling a coorindate of $\vec{a}$ we obtained at most $O((c\log(n))^{2q})$-error in the sampling probability. Thus, by oversampling by a $O((c\log(n))^{2q^2})$ factor, we can obtain the desired sampling probabilities. This completes the proof of correctness. Note that to improve the failure probability to $1-\delta$, we can simply scale r_3 by a factor of $1/\delta$.

Proof of Runtime. We now analyze the runtime. At every step $i=1,2,\ldots,q$ of the sampling, we compute $v_i^j \leftarrow S^i\left((\bigotimes_{k=1}^{i-1}e_{a_k}^\top)\otimes(\mathbb{I}_{n_i})\otimes(\bigotimes_{k=i+1}^{q}Z^{k,j})\rho\right)\in\mathbb{R}^{n_i}$ for $j=1,2,\ldots\Theta(\log(n))$. This is equal to

$$S^i\left((\bigotimes_{k=1}^{i-1}(A_k)_{a_k,*})\otimes(A_i)\otimes(\bigotimes_{k=i+1}^{q}Z^{k,j}A_k)x' - (\bigotimes_{k=1}^{i-1}e_{a_k}^\top)\otimes(\mathbb{I}_{n_i})\otimes(\bigotimes_{k=i+1}^{q}Z^{k,j})b\right)$$

We first consider the term inside of the parenthesis (excluding S^i). Note that the term $(\bigotimes_{k=i+1}^{q} Z^{k,j} A_k)$ was already pre-computed, and is a vector of length at most d, this this requires a total of $\widetilde{O}(\sum_{i=1}^{q} \operatorname{nnz}(A_i) + d)$ time. Note that these same values are used for every sample. Given this pre-computation, we can rearrage the first term to write $(\bigotimes_{k=1}^{i-1}(A_k)_{a_k,*}) \otimes (A_i) X' (\bigotimes_{k=i+1}^{q} Z^{k,j} A_k)^\top$ where X' is a matrix formed from x' so that x' is the vectorization of X' (this is done via reshaping Lemma 26.8.1). The term $y = X'(\bigotimes_{k=i+1}^{q} Z^{k,j} A_k)^\top$ can now be computed in $O(d)$ time, and then we reshape again to write this as $(\bigotimes_{k=1}^{i-1}(A_k)_{a_k,*}) Y A_i^\top$ where Y again is a matrix formed from y. Observe that $\zeta = \operatorname{vec}(\bigotimes_{k=1}^{i-1}(A_k)_{a_k,*} Y) \in \mathbb{R}^{d_i}$ can be computed in time $O(qd)$, since each entry is a dot product of a column $Y_{*,j} \in \mathbb{R}^{d_1 \cdot d_2 \cdots d_{i-1}}$ of Y with the $d_1 \cdot d_2 \cdots d_{i-1}$ dimensional vector $\bigotimes_{k=1}^{i-1}(A_k)_{a_k,*}$, which can be formed in $O(d_1 \cdot d_2 \cdots d_{i-1} q)$ time, and there are a total of d_i columns of Y.

Given this, The first entire term $S^i(\bigotimes_{k=1}^{i-1}(A_k)_{a_k,*}) \otimes (A_i) \otimes (\bigotimes_{k=i+1}^{q} Z^{k,j} A_k) x'$ can be rewritten as $S^i A_i \zeta$, where $\zeta = \zeta_{\vec{a}} \in \mathbb{R}^{d_i}$ can be computed in $O(dq)$ time for each sample $\vec{a}$. Thus if we recompute the value $S_i A_i \in \mathbb{R}^{k \times n}$, where $k = \widetilde{O}(r_3^{16})$, which can be done in time $\widetilde{O}(\operatorname{nnz} A_i)$, then every time we are sampling the i-th coordinate of some $\vec{a}$, computing the value of $S^i A_i \zeta_{\vec{a}}$ can be done in time $O(k d_i^2) = r_3^{O(1)}$.

We now consider the second term. We do a similar trick, reshaping $b \in \mathbb{R}^n$ into $B \in \mathbb{R}^{(n_1 \cdots n_i) \times (n_i \cdots n_q)}$ and writing this term as $((\bigotimes_{k=1}^{i-1} e_{a_k}^\top) \otimes (\mathbb{I}_{n_i})) B (\bigotimes_{k=i+1}^{q} Z^{k,j})^\top$ and computing $b' = B(\bigotimes_{k=i+1}^{q} Z^{k,j})^\top \in \mathbb{R}^{(n_1 \cdots n_i)}$ in $\operatorname{nnz}(B) = \operatorname{nnz}(b)$ time. Let $B' \in \mathbb{R}^{(n_1 \cdots n_{i-1}) \times n_i}$ be such that $\operatorname{vec}(B') = b'$, and we reshape again to obtain $(\bigotimes_{k=1}^{i-1} e_{a_k}^\top) B' (\mathbb{I}_{n_i}) = (\bigotimes_{k=1}^{i-1} e_{a_k}^\top) B'$ Now note that so far, the value B' did not depend on the sample $\vec{a}$ at all. Thus for each $i = 1, 2, \ldots, q$, B' (which depends only on i) can be pre-computed in $\operatorname{nnz}(b)$ time. Given this, the value $(\bigotimes_{k=1}^{i-1} e_{a_k}^\top) B'$ is just a row $B'_{(a_1,\ldots,a_k),*}$ of B' (or a column of $(B')^\top$). We

first claim that $nnz(B') \leq \text{nnz}(b) = \text{nnz}(B)$. To see this, note that each entry of B' is a dot product $B_{j,*}(\bigotimes_{k=i+1}^{q} Z^{k,j})^\top$ for some row $B_{j,*}$ of B, and moreover there is a bijection between these dot products and entries of B'. Thus for every non-zero entry of B', there must be a unique non-zero row (and thus non-zero entry) of B. This gives a bijection from the support of B' to the support of B (and thus b) which completes the claim. Since $S^i(B'_{(a_1,\ldots,a_k),*})^\top$ can be computed in $\widetilde{O}(\text{nnz}(B'_{(a_1,\ldots,a_k),*}))$ time, it follows that $S^i(B'_{(a_1,\ldots,a_k),*})^\top$ can be computed for all rows $(B'_{(a_1,\ldots,a_k),*})$ of B in $\widetilde{O}(\text{nnz}(b))$ time. Given this precomputation, we note that $(\mathbb{I}_{n_i}) \otimes (\bigotimes_{k=i+1}^{q} Z^{k,j})b$ is just $S^i(B'_{(a_1,\ldots,a_k),*})^\top$ for some $(a_1,\ldots,a_k)$, which has already been pre-computed, and thus requires no addition time per sample. Thus, given a total of $\widetilde{O}(\sum_{i=1}^{q} \text{nnz}(A_i) + q\,\text{nnz}(b) + r_3^{O(1)})$ pre-processing time, for each sample we can compute v_i^j for all $i \in [q]$ and $j \in [\tau]$ in $\widetilde{O}(r_3^{O(1)})$ time, and thus $\widetilde{O}(r_3^{O(1)})$ time over all r_3 samples.

Given this, the procedure to compute the heavy hitters $H_{i,j}$ takes $\widetilde{O}(r_3^{16})$ time by Definition 26.8.2 for each sample and $i \in [q], j \in [\tau]$. By a identical pre-computation and rearrangement argument as above, each β_i^j (and thus β_i) can be computed in $\widetilde{O}(r_3^{O(1)})$ time per sample after pre-computation. Now note that γ_i is simply equal to median $j \in [\tau](\beta_i^j - (\bigotimes_{k=1}^{i-1} e_{a_k}^\top) \otimes (Z_{H_i}^{k,j}) \otimes (\bigotimes_{k=i+1}^{q} Z^{k,j})\rho)$. Since $(Z_{H_i}^{k,j})$ is sparse, the above can similar be computed in $O(d|H_i|) = \widetilde{O}(r_3^{O(1)})$ time per sample after pre-computation. To see this, note that the b term of $(\bigotimes_{k=1}^{i-1} e_{a_k}^\top) \otimes (Z_{H_i}^{k,j}) \otimes (\bigotimes_{k=i+1}^{q} Z^{k,j})\rho$ can be written as $(\bigotimes_{k=1}^{i-1} e_{a_k}^\top)B'''(Z_{H_i}^{k,j})^\top$, where $B''' \in \mathbb{R}^{n_1 \cdots n_{i-1} \times n_i}$ is a matrix that has already been pre-computed and does not depend on the given sample. Then this quantity is just the dot product of a row of B''' with $(Z_{H_i}^{k,j})^\top$, but since $(Z_{H_i}^{k,j})$ is $|H_i|$-sparse, so the claim for the b term follows. For the $(A_1 \otimes \cdots \otimes A_q)$ term, just as we demonstrated in the discussion of computing v_i^j, note that

this can be written as $(\bigotimes_{k=1}^{i-1}(A_k)_{a_k,*})Y((A_i)_{H_i,*})^\top$ for some matrix $Y \in \mathbb{R}^{d_1\cdots d_i \times d_{i-1}}$ that has already been precomputed. Since $(A_i)_{H_i,*}$ only has $O(|H_i|)$ non-zero rows, this whole product can be computed in time $O(d|H_i|)$ as needed.

Similarly, we can compute the sampling probabilities

$$\Pr\left[\text{sample } a_i \leftarrow j\right] = \frac{\text{median}_{j\in\tau}\left|\left((\bigotimes_{k=1}^{i-1} e_{a_k}^\top)\otimes(e_\xi^\top)\otimes(\bigotimes_{k=i+1}^{q} Z^{k,j})\rho\right)\right|^p}{\sum_{\xi'\in H_i}\text{median}_{j\in\tau}\left|\left((\bigotimes_{k=1}^{i-1} e_{a_k}^\top)\otimes(e_{\xi'}^\top)\otimes(\bigotimes_{k=i+1}^{q} Z^{k,j})\rho\right)\right|^p}$$

for each every item $\zeta \in H_i$ in $\widetilde{O}(r_3^{O(1)})$ time after pre-computation, and note $|H_i| = \widetilde{O}(r_3^{O(1)})$ by definition 26.8.2. Thus the total time to sample a heavy hitter in a given coordinate $i \in [q]$ for each sample $\widetilde{O}(r_3^{O(1)})$ per sample, for an overall time of $\widetilde{O}(qr_3^{O(1)})$ over all samples and $i \in [q]$.

Finally, we consider the runtime for sampling a non-heavy item. Note that $|\Omega_t| = O(n_i/\eta)$ with high probability for all $t \in [\eta]$ by chernoff bounds. Computing each

$$\theta_j = \underset{l\in[\tau]}{\text{median}}\left(\left|(\bigotimes_{k=1}^{i-1} e_{a_k}^\top)\otimes(e_j^\top)\otimes(\bigotimes_{k=i+1}^{q} Z^{k,l})\rho\right|^p\right)$$

takes $O(qd)$ time after pre-computation, and so we spend a total of $O(qdn_i/\eta)$ time sampling an item from $\Omega_t \setminus H_i$. Since we only ever sample a total of r_3 samples, and $\eta = \Theta(r_3^2)$, the total time for sampling non-heavy hitters over the course of the algorithm in coordinate i is $o(n_i) = o(\text{nnz}(A_i))$ as needed, which completes the proof of the runtime.

Computing the Sampling Probabilities α_i The above arguments demonstrate how to sample efficiently from the desired distribution. We now must describe how the sampling probabilities α_i can be computed. First note, for each sample that is sampled in the above

way, at every step we compute exactly the probability with which we decide to sample a coordinate to that sample. Thus we know exactly the probability that we choose a sample, and moreover we can compute each q_i in $O(d)$ time as in Lemma 26.8.4. Thus we can compute the maximum of q_i and this probability exactly. For each item sampled as a result of the leverage score sampling probabilities q_i as in Lemma 26.8.4, we can also compute the probability that this item was sampled in the above procedure, by using the same sketching vectors $Z^{i,k}$ and count-sketches S^i. This completes the proof of the Lemma.

□

26.9 Missing Proofs from Section 26.4

In this section, we prove the correctness of our all-pairs regression algorithm 26.3. Our main theorem, Theorem 26.4.1, relies crucially on the sample routine developed in Section 26.9.1. We first prove the theorem which utilizes this routine, and defer the description and proof of the routine to Section 26.9.1.

Recall first the high level description of our algorithm (given formally in Figure 26.3). We pick $S_1, S_2 \in \mathbb{R}^{k \times n}$and S are sparse p-stable sketches. We then compute $M = (S_1 \otimes S_2)(F \otimes \mathbf{1} - \mathbf{1} \otimes F) = S_1F \otimes S_2\mathbf{1} - S_1\mathbf{1} \otimes S_2F$, where $F = [A, b]$. We then take the QR decomposition $M = QR$. Finally, we sample rows of $(F \otimes \mathbf{1} - \mathbf{1} \otimes F)R^{-1}$ with probability proportional to their ℓ_p norms. This is done by the sampling procedure described in Section 26.9.1. Finally, we solve the regression problem $\min_x \|\Pi(\bar{A}x - \bar{b})\|_p$, where Π is the diagonal row-sampling matrix constructed by the sampling procedure.

We begin by demonstrating that $S_1 \otimes S_2$ is a poly(d) distortion embedding for the

column span of $[\bar{A}, \bar{b}]$.

Lemma 26.9.1. *Let $S_1, S_2 \in \mathbb{R}^{k \times n}$ be sparse p-stable transforms, where $k = \text{poly}(d/(\epsilon\delta))$. Then for all $x \in \mathbb{R}^{d+1}$, with probability $1 - \delta$ we have*

$$1/O(d^4 \log^4 d)\|[\bar{A}, \bar{b}]x\|_p \leq \|(S_1 \otimes S_2)[\bar{A}, \bar{b}]x\|_p \leq O(d^2 \log^2 d)\|[\bar{A}, \bar{b}]x\|_p$$

Proof. Let $F = [A, b]$. Then a basis for the columns of $[\bar{A}, \bar{b}]$ is given by $F \otimes \mathbf{1} - \mathbf{1} \otimes F$. We first condition on both S_1, S_2 being a low-distortion embedding for the $d + 2$ dimensional column-span of $[F, \mathbf{1}]$. Note that this holds with large constant probability by 26.2.1.

So for any $x \in \mathbb{R}^{d+1}$, we first show the upper bound

$$\begin{aligned}
\|(S_1 \otimes S_2)(F \otimes \mathbf{1} - \mathbf{1} \otimes F)x\|_p &= \|(S_1 F \otimes S_2 \mathbf{1})x - (S_1 \mathbf{1} \otimes S_2 F)\|_p \\
&= \|S_1 F x \mathbf{1}^\top S_2^\top - S_1 \mathbf{1} x^\top F^\top S_2^\top\|_p \\
&= \|S_1(F x \mathbf{1}^\top - \mathbf{1} x^\top F^\top) S_2^\top\|_p \\
&\leq O(d \log d)\|(F x \mathbf{1}^\top - \mathbf{1} x^\top F^\top) S_2^\top\|_p \\
&\leq O(d^2 \log^2 d)\|F x \mathbf{1}^\top - \mathbf{1} x^\top F^\top\|_p \\
&= O(d^2 \log^2 d)\|(F \otimes \mathbf{1} - \mathbf{1} \otimes F)x\|_p
\end{aligned}$$

Where the first equality follows by properties of the Kronecker product [VL00], the second by reshaping Lemma 26.8.1. The first inequality follows from the fact that each column of $(F x \mathbf{1}^\top - \mathbf{1} x^\top F^\top) S_2^\top$ is a vector in the column span of $[F, \mathbf{1}]$, and then using that S_1 is a low distortion embedding. The second inequality follows from the fact that each row of $(F x \mathbf{1}^\top - \mathbf{1} x^\top F^\top)$ is a vector in the *column span* of $[F, \mathbf{1}]$, and similarly using that S_2 is a low

distortion embedding. The final inequality follows from reshaping. Using a similar sequence of inequalities, we get the matching lower bound as desired. □

We now prove our main theorem.

Theorem 26.4.1 *Given $A \in \mathbb{R}^{n\times d}$ and $b \in \mathbb{R}^n$, for $p \in [1,2]$ there is an algorithm for the All-Pairs Regression problem that outputs $\widehat{x} \in \mathbb{R}^d$ such that with probability $1-\delta$ we have*

$$\|\bar{A}\widehat{x} - \bar{b}\|_p \leq (1+\epsilon)\min_{x\in\mathbb{R}^d} \|\bar{A}x - \bar{b}\|_p$$

Where $\bar{A} = A \otimes \mathbf{1} - \mathbf{1} \otimes A \in \mathbb{R}^{n^2\times d}$ and $\bar{b} = b \otimes \mathbf{1} - \mathbf{1} \otimes b \in \mathbb{R}^{n^2}$. For $p < 2$, the running time is $\widetilde{O}(nd + (d/(\epsilon\delta))^{O(1)})$, and for $p = 2$ the running time is $O(\mathrm{nnz}(A) + (d/(\epsilon\delta))^{O(1)})$.

Proof. We first consider the case of $p = 2$. Here, we can use the fact that the TensorSketch random matirx $S \in \mathbb{R}^{k\times n}$ is a subspace embedding for the column span of $[\bar{A}, \bar{b}]$ when $k = \Theta(d/\epsilon^2)$ [DSSW18], meaning that $\|S[\bar{A}, \bar{b}]\|_2 = (1 \pm \epsilon)\|[\bar{A}, \bar{b}]x\|_2$ for all $x \in \mathbb{R}^{d+1}$ with probability 9/10. Moreover, $S\bar{A}$ and $S\bar{b}$ can be computed in $O(\mathrm{nnz}(A)+\mathrm{nnz}(b)) = O(\mathrm{nnz}(A))$ by [DSSW18] since they are the difference of Kronecker products. As a result, we can simply solve the regression problem $\widehat{x} = \arg\min_x \|S\bar{A}x - S\bar{b}\|_2$ in $\mathrm{poly}(kd)$ time to obtain the desired $\widehat{x}$.

For $p < 2$, we use the algorithm in Figure 26.3, where the crucial leverage score sampling procedure to obtain Π in step 7 of Figure 26.3 is described in Lemma 26.4.2. Our high level approach follows the general ℓ_p sub-space embedding approach of [DDH+09]. Namely, we first compute a low-distortion embedding $(S_1 \otimes S_2)(F \otimes \mathbf{1} - \mathbf{1} \otimes F)$. By Lemma 26.9.1, using sparse-p stable transformations S_1, S_2, we obtain the desired $\mathrm{poly}(d)$ distortion

embedding into $\mathbb{R}^{k^2}$, where $k = \text{poly}(d/\epsilon)$. Note that computing $(S_1 \otimes S_2)(F \otimes \mathbf{1} - \mathbf{1} \otimes F)$ can be done in $O(\text{nnz}(A) + \text{nnz}(b) + n)$ time using the fact that $(S_1 \otimes S_2)(F \otimes \mathbf{1}) = S_1 F \otimes S_2 \mathbf{1}$. As shown in [DDH+09], it follows that $M = (F \otimes \mathbf{1} - \mathbf{1} \otimes F)R^{-1}$ is an ℓ_p well-conditioned basis for the column span of $(F \otimes \mathbf{1} - \mathbf{1} \otimes F)$ (see definition 26.2.4). Then by Theorem 5 of [DDH+09], if we let $\widehat{\Pi}$ be the diagonal row sampling matrix such that $\widehat{\Pi}_{i,i} = 1/q_i^{1/p}$ for each i with probability $q_i \geq \min\{1, r\|M_{i,*}\|_p^p / \|M\|_p^p\}$ (and $\widehat{\Pi}_{i,i} = 0$ otherwise) for $r = \text{poly}(d \log(1/\delta)/\epsilon)$, then with probability $1 - \delta$ we have $\|\widehat{\Pi}(F \otimes \mathbf{1} - \mathbf{1} \otimes F)x\|_p = (1 \pm \epsilon)\|(F \otimes \mathbf{1} - \mathbf{1} \otimes F)x\|_p$ for all $x \in \mathbb{R}^{d+1}$. First assume that we had such a matrix.

Since $(\bar{A}x - \bar{b})$ is in the column span of $(F \otimes \mathbf{1} - \mathbf{1} \otimes F)$ for any $x \in \mathbb{R}^{d+1}$, it follows that $\|\widehat{\Pi}(\bar{A}x - \bar{b})\|_p = (1 \pm \epsilon)\|(\bar{A}x - \bar{b})\|_p$ for all $x \in \mathbb{R}^d$, which completes the proof of correctness. By Lemma 26.4.2, we can obtain a row sampling matrix Π in time $\widetilde{O}(nd + \text{poly}(d/\epsilon))$, except that the entries of Π are instead equal to either 0 or $1/\widetilde{q}_i^{1/p}$ where $\widetilde{q}_i = (1 \pm \epsilon^2)q_i$. Now let $\widehat{\Pi}$ be the idealized row sampling matrices from above, with entries either 0 or $1/q_i^{1/p}$ as needed for Theorem 5 of [DDH+09]. Note that for any matrix Z each row of $\widehat{\Pi}Zx$ is equal to ΠZx times some constant $1 - \epsilon^2 < c < 1 + \epsilon^2$. It follows that $\|\Pi(\bar{A}x - \bar{b})\|_p = (1 \pm \epsilon^2)\|\widehat{\Pi}(\bar{A}x - \bar{b})\|_p$ for all $x \in \mathbb{R}^d$, and thus the objective function is changed by at most a $(1 \pm \epsilon^2)$ term, which is simply handled by a constant factor rescaling of ϵ.

Finally, we can solve the sketched regression problem $\|\Pi(\bar{A}x - \bar{b})\|_p$ which has $\text{poly}(d/\epsilon)$ constraints and d variables in time $\text{poly}(d/\epsilon)$ using linear programming for $p = 1$ (see [CLS19] for the state of the art linear program sovler), or more generally interior point methods for convex programming for $p > 1$ (see [BCLL18] for the state of the art ℓ_p solver. Finally, the failure probability bound holds by union bounding over all the aforementioned results, and noting that the lowest probability event was the even that $S_1 \otimes S_2$ was a low distortion

embedding via Lemma 26.9.1. This completes the proof of the theorem.

□

26.9.1 Proof of Fast Sampling Lemma 26.4.2

We now provide a full proof of the main technical lemma of Section 26.4. The sampling algorithm is given formally in Algorithm 26.5. The following proof of Lemma 26.4.2 analyzes each step in the process, demonstrating both correctness and the desired runtime bounds.

Lemma 26.4.2 *Given $R \in \mathbb{R}^{(d+1)\times(d+1)}$ and $F = [A, b] \in \mathbb{R}^{n\times(d+1)}$, there is an algorithm that, with probability $1-\delta$ for any $\delta > n^{-c}$ for any constant c, produces a diagonal matrix $\Pi \in \mathbb{R}^{n^2\times n^2}$ such that $\Pi_{i,i} = 1/\widetilde{q}_i^{1/p}$ with probability $q_i \geq \min\{1, r\|M_{i,*}\|_p^p/\|M\|_p^p\}$ and $\Pi_{i,i} = 0$ otherwise, where $r = \mathrm{poly}(d/\epsilon)$ and $M = (F\otimes \mathbf{1} - \mathbf{1}\otimes F)R^{-1}$, and $\widetilde{q}_i = (1\pm\epsilon^2)q_i$ for all $i \in [n^2]$. The total time required is $\widetilde{O}(\mathrm{nnz}\, A + \mathrm{poly}(d/\epsilon))$.*

Proof. Our proof proceeds in several steps. We analyze the runtime concurrently with out analysis of correctness.

Reducing the number of Columns of R^{-1} We begin by generating a matrix $G \in \mathbb{R}^{(d+1)\times\xi}$ of i.i.d. $\mathcal{N}(0, 1/\sqrt{\xi})$ Gaussian random variables. We then compute $Y \leftarrow R^{-1}G$ in $\widetilde{O}(d^2)$ time. We first claim that it suffices to instead ℓ_p sample rows of $C = (F\otimes\mathbf{1}-\mathbf{1}\otimes F)Y = MG$. Note that each entry $|C_{i,j}|^p$ is distributed as $g^p\|M_{i,*}\|_2^p$ where G $\mathcal{N}(0, 1/\sqrt{\xi})$ Gaussian, which holds by the 2-stability of Gaussian random variables. Note that $\mathbb{E}[|g|^p] = \Theta(1/\xi)$, so $\mathbb{E}[\|C_{i,*}\|_p^p] = \|M_{i,*}\|_2^p$, and by sub-exponential concentration (see Chapter 2 of [Wai19]), we have that $\|C_{i,*}\|_p^p = (1\pm 1/10)\|M_{i,*}\|_2^p$ with probability $1 - 1/\mathrm{poly}(n)$, and we can union

bound over this holding for all $i \in [n^2]$. By relationships between the p norms, we have $\|M_{i,*}\|_p^p/d < \|M_{i,*}\|_2^p < \|M_{i,*}\|_p^p$, thus this changes the overall sampling probabilities by a factor between $\Theta(1/d^2)$ and $\Theta(d^2)$. Thus, we can safely oversample by this factor (absorbing it into the value of r) to compensate for this change in sampling probabilities.

Sampling a row from C. To sample a row from C, the approach will be to sample an entry $C_{i,j}$ of C with probability proportional to $\|C_{i,j}\|_p^p/\|C\|_p^p$. For every (i,j) sampled, we sample the entire i-th row of j, so that the j-th row is indeed sampled with probability proportional to its norm. Thus, it suffices to sample entries of C such that each $C_{i,j}$ is chosen with probability at least $\min\{1, r\|C_{i,j}\|_p^p/\|C\|_p^p\}$. First note that the i-th column of $C = (F \otimes \mathbf{1} - \mathbf{1} \otimes F)Y$ can be rearranged into a $n \times n$ matrix via Lemma 26.8.1, given by $(FY_{*,i}\mathbf{1}^\top - \mathbf{1}Y_{*,i}^\top F^\top)$. To ℓ_p sample a coordinate from C, it suffices to first ℓ_p sample a column of one of the above matrices, and then ℓ_p sample an entry from that column.

To do this, we first compute $FY \in \mathbb{R}^{n \times \xi}$, which can be done in time $\widetilde{O}(\text{nnz}\, A)$ because Y only has $\xi = \Theta(\log(n))$ columns. We then compute $Z(FY_{*,i}\mathbf{1}^\top - \mathbf{1}Y_{*,i}^\top F^\top) \in \mathbb{R}^{1 \times n}$ for all $i \in [d]$, where $Z \in \mathbb{R}^{1 \times n}$ is a fixed vector of i.i.d. p-stable random variables. Once FY has been computed, for each $i \in [\xi]$ it takes $O(n)$ time to compute this n-dimensional vector, thus the total time required to compute all ξ vectors is $\widetilde{O}(n)$. We repeat this process $t = O(\log(n))$ times with different p-stable vectors $Z^1, \ldots, Z^\top$, and take the median of each coordinate of $Z^j(FY_{*,i}\mathbf{1}^\top - \mathbf{1}Y_{*,i}^\top F^\top) \in \mathbb{R}^n$, $j \in [t]$, divided by the median of the p-stable distribution (which can be approximated to $(1 \pm \epsilon)$ error in $\text{poly}(1/\epsilon)$ time, see Appendix A.2 of [KNW10b] for details of this). This is done in Step 7 of Algorithm 26.5. It is standard this this gives a $(1 \pm 1/10)$ approximation the the norm $\|(FY_{*,i}\mathbf{1}^\top - \mathbf{1}Y_{*,i}^\top F^\top)_{*,l}\|_p$ for each

$i \in [d], l \in [n]$ with probability $1 - 1/\operatorname{poly}(n)$ (See the Indyk median estimator [Ind06]).

Now let $\sigma_{i,l}$ be our estimate of the norm $\|(FY_{*,i}\mathbf{1}^\top - \mathbf{1}Y_{*,i}^\top F^\top)_{*,l}\|_p$, for all $i \in [\xi]$ and $l \in [n]$. We now sample a columns $(i,l) \in [\xi] \times [n]$, where each (i,l) is chosen with probability $\sigma_{i,l}/(\sum_{i',l'} \sigma_{i',l'})$. We repeat this process $\Theta(r)$ times, to obtain a *multi-set* $T \subset [\xi] \times [n]$ of sampled columns (i,l). We stress that T is a multi-set, because the same column (i,l) may have been chosen for multiple samples, and each time it is chosen we must independently sample one of the entries of that column. For any $(i,l) \in T$, we define $W^{(i,l)} = (FY_{*,i}\mathbf{1}^\top - \mathbf{1}Y_{*,i}^\top F^\top)_{*,l} = (FY_{*,i} - \mathbf{1}(FY)_{l,i})$.

ℓ_p Sampling an entry from $W^{(i,l)}$. Now fix any $(i,l) \in T$. We show how to ℓ_p sample an entry from the vector $W^{(i,l)} \in \mathbb{R}^n$. In other words, for a given $j \in [n]$, we want to sample $W_j^{(i,l)} \in [n]$ with probability at least $r|W_j^{(i,l)}|^p/\|W^{(i,l)}\|_p^p$. We do this in two steps. First, let $S_0 \in \mathbb{R}^{k \times n}$ be the count-sketch for heavy hitters of definition 26.8.2, where $k = \operatorname{poly}(r)$. Note that we can compute $S_0 FY$ and $S_0\mathbf{1}$ in time $\widetilde{O}(n)$, since $FY \in \mathbb{R}^{n \times \xi}$. Once this is done, for each $(i,l) \in T$ we can compute $S_0 W^{(i,l)}$ in $O(k)$ time by computing $(S_0\mathbf{1}(FY)_{l,i})$ (note that FY and $S_0\mathbf{1}$ are already computed), and subtracting it off from the i-th column of $S_0 FY$, so the total time is $\widetilde{O}(n + \operatorname{poly}(d/\epsilon))$ to compute $S_0 W^{(i,l)}$ for all $(i,l) \in |T|$. Now we can obtain the set $Q_0^{(i,l)} \subset [n]$ containing all the $\widetilde{\Omega}(1/\sqrt{k})$ heavy hitters in $W^{(i,l)}$ with high probability. We can then explicitly compute the value of $W_j^{(i,l)}$ for all $j \in Q_0^{(i,l)}$, and exactly compute the set

$$H^{(i,l)} = \left\{ j \in [n] \;\middle|\; |W_j^{(i,l)}|^p > \beta/r^{16}\|W^{(i,l)}\|_p^p \right\},$$

all in $\widetilde{O}(k)$ time via definition 26.8.2, where $\beta > 0$ is a sufficiently small constant (here we use the fact that $|x|_p \geq |x|_2$ for $p \leq 2$). Note that we use the same sketch S_0 to compute all

sets $Q_0^{(i,l)}$, and union bound the event that we get the heavy hitters over all poly(d/ϵ) trails.

We are now ready to show how we sample an index from $W^{(i,l)}$. First, we estimate the total ℓ_p norm of the items in $[n_i] \setminus H^{(i,l)}$ (again with the Indyk median estimator), and call this $\alpha_{(i,l)}$ as in Algorithm 26.5, which can be computed in $O(|H^{(i,l)}|)$ additional time (by subtracting off the $|H^{(i,l)}|$ coordinates $ZW_\zeta^{(i,l)}$ for all heavy hitters $\zeta \in H^{(i,l)}$ from our estimate $\sigma_{(i,l)}$), and with probability $\alpha_{(i,l)}/\sigma_{(i,l)}$, we choose to sample one of the items of $H^{(i,l)}$, which we can then sample from the distribution $|W_j^{(i,l)}|^p/(\sum_{j\in H^{(i,l)}} |W_j^{(i,l)}|^p)$. Since all the $\sigma_{(i,l)}, \alpha_{(i,l)}$'s were constant factor approximations, it follows that we sampled such an item with probability $\Omega(r|W_{j'}^{(i,l)}|^p/\|C\|_p^p)$ as needed. Otherwise, we must sample an entry from $[n] \setminus H^{(i,l)}$. To do this, we first randomly partition $[n]$ into $\eta = \Theta(r^4/\epsilon^4)$ subsets $\Omega_1, \Omega_2, \ldots, \Omega_\eta$.

We now make the same argument made in the proof of Lemma 26.8.7, considering two cases. In the first case, the ℓ_p mass of $[n]\setminus H^{(i,l)}$ drops by a $1/r^2$ factor after removing the heavy hitters. In this case, $\alpha_{(i,l)}/\sigma_{(i,l)} = O(1/r^2)$, thus we will never *not* sample a heavy hitter with probability $1-O(1/r)$, which we can safely ignore. Otherwise, the ℓ_p drops by less than a $1/r^2$ factor, and it follows that all remaining items must be at most a β/r^{14} heavy hitter over the remaining coordinates $[n]\setminus H^{(i,l)}$ (since if they were any larger, they would be β/r^{16} heavy hitters in $[n]$, and would have been removed in $H^{(i,l)}$). Thus we can assume we are in the second case. So by Chernoff bounds, we have $\sum_{j\in\Omega_t} |W_j^{(i,l)}|_p = \Theta(\frac{1}{\eta}\sum_{j\in[n]\setminus H^{(i,l)}} |W_j^{(i,l)}|_p)$ with probability greater than $1-\exp(-\Omega(r))$. We can then union bound over this event occurring for all $t \in [\eta]$ and all $(i,l) \in T$. Given this, if we uniformly sample a $t \sim [\eta]$, and then ℓ_p sample a coordinate $j \in \Omega_t$, we will have sampled this coordinate with the correct probability up to a constant factor. We now sample such a t uniformly from η.

To do this, we generate a diagonal matrix $D \in \mathbb{R}^{n \times n}$, where $D_{i,i} = 1/u_i^{1/p}$, where $u_1, \ldots, u_n$ are i.i.d. exponential random variables. For any set $\Gamma \subset [n]$, let D_Γ be D with all diagonal entries (j, j) such that $j \notin \Gamma$ set equal to 0. Now let $S \in \mathbb{R}^{k' \times n}$ be a second instance of count-sketch for heavy hitters of definition 26.8.2, where we set $k' = \text{poly}(k)$ from above. It is known that returning $j^* = \arg\max_{j \in \Omega_t \setminus H^{(i,l)}} |(DW^{(i,l)})_j|$ is a perfect ℓ_p sample from $\Omega_t \setminus H^{(i,l)}$ [JW18]. Namely, $\Pr[j^* = j] = |W_j^{(i,l)}|^p / \|W_{\Omega_t \setminus H^{(i,\ell)}}\|_p^p$ for any $j \in \Omega_t \setminus H^{(i,\ell)}$. Thus it will suffice to find this j^*. To find j^*, we compute $S(DW)_{\Omega_t \setminus H^{(i,\ell)}}$. Note that since FY has already been computed, to do this we need only compute $SD_{\Omega_t \setminus H^{(i,\ell)}} FY_{*,i}$ and $SD_{\Omega_t \setminus H^{(i,\ell)}} \mathbf{1}(FY)_{\ell,i}$, which takes total time $\widetilde{O}(|\Omega_t \setminus H^{(i,\ell)}|) = \widetilde{O}(n/\eta)$. We then obtain a set $Q^{(i,l)} \subset \Omega_t \setminus H^{(i,\ell)}$ which contains all j with $|(DW^{(i,l)})_j| \geq \widetilde{\Omega}(1/\sqrt{k'}) \|(DW)_{\Omega_t \setminus H^{(i,\ell)}}\|_2$.

As noted in [JW18], the value $\max_{j \in \Omega_t \setminus H^{(i,l)}} |(DW^{(i,l)})_j|$ is distributed identically to $\|W_{\Omega_t \setminus H^{(i,\ell)}}\|_p / u^{1/p}$ where u is again an exponential random variable. Since exponential random variables have tails that decay like $e^{-\Omega(x)}$, it follows that with probability $1 - \exp(-\Omega(r))$ that we have $\max_{j \in \Omega_t \setminus H^{(i,l)}} |(DW^{(i,l)})_j| = \Omega(\|W_{\Omega_t \setminus H^{(i,\ell)}}\|_p / r)$, and we can then union bound over the event that this occurs for all $(i, l) \in T$ and Ω_t. Given this it follows that $(DW^{(i,l)})_{j^*} = \Omega(\|W_{\Omega_t \setminus H^{(i,\ell)}}\|_p / r)$. Next, for any constant $c \geq 2$, by Proposition 1 of [JW18], we have $\|((DW)_{\Omega_t \setminus H^{(i,\ell)}})_{\texttt{tail}(c \log(n))}\|_2 = \widetilde{O}(\|W^{(i,l)}_{\Omega_t \setminus H^{(i,\ell)}}\|_p)$ with probability $1 - n^{-c}$, where for a vector x, $x_{(\overline{[t]})}$ is x but with the top t largest (in absolute value) entries set equal to 0. Since there are at most $c \log(n)$ coordinates in $(DW)_{\Omega_t \setminus H^{(i,\ell)}}$ not counted in $((DW)_{\Omega_t \setminus H^{(i,\ell)}})_{\texttt{tail}(c \log(n))}$, and since $(DW)_{j^*}$ is the largest coordinate in all of $(DW)_{\Omega_t \setminus H^{(i,\ell)}}$, by putting together all of the above it follows that $(DW)_{j^*}$ is a $\widetilde{\Omega}(1/r)$-heavy hitter in $(DW)_{\Omega_t \setminus H^{(i,\ell)}}$. Namely, that $|(DW)_{j^*}| \geq \widetilde{\Omega}(\|(DW)_{\Omega_t \setminus H^{(i,\ell)}}\|_2 / r)$. Thus, we conclude that $j^* \in Q^{(i,l)}$.

Given that $j^* \in Q^{(i,l)}$, we can then compute the value $(DW^{(i,l)})_j = D_{j,j}(FY_{j,i} - FY_{l,i})$ in $O(1)$ time to find the maximum coordinate j^*. Since $|Q^{(i,l)}| = O(k') = O(\text{poly}(d/\epsilon))$, it follows that the total time required to do this is $\widetilde{O}(n/\eta + \text{poly}(d/\epsilon))$. Since we repeat this process for each $(i,l) \in T$, and $|T| = \Theta(r)$ whereas $\eta = \Theta(r^4)$, it follows that the total runtime for this step is $\widetilde{O}(n/r^3 + \text{poly}(d/\epsilon))$. By [JW18], the result is a perfect ℓ_p sample from $(DW)_{\Omega_t \setminus H^{(i,\ell)}}$, which is the desired result. To complete the proof, we note that the only complication that remains is that we utilize the same scaling matrix D to compute the sampled used in each of the columns $W^{(i,l)}$ for each $(i,l) \in T$. However, note that for $t \neq t'$, we have that D_{Ω_t} and D_{Ω_t} are independent random variables. Thus it suffices to condition on the fact that the $t \in [\eta]$ that is sampled for each of the $|T|$ repetitions of sampling a Ω_t are distinct. But this occurs with probability at least $1/r$, since $|T| = \Theta(r)$ and $\eta = \Theta(r^4)$. Conditioned on this, all $|T|$ samples are independent, and each sample is an entry $C_{i,j}$ of C such that the probability that a given (i,j) is chosen is $|C_{i,j}|^p / \|C\|_p^p$. Repeating this sampling $\Theta(r)$ times, we get that each $C_{i,j}$ is sampled with probability at least $\min\{1, r|C_{i,j}|^p/\|C\|_p^p\}$, which completes the proof of correctness. Note that the dominant runtime of the entire procedure was $\widetilde{O}(\text{nnz}(A) + \text{poly}(d/\epsilon))$ as stated, and the probability of success was $1 - \exp(-r) + 1/\text{poly}(n)$, which we can be amplified to any $1 - \delta$ for $\delta > 1/n^c$ for some constant c by increasing the value of r by $\log(1/\delta)$ and the number of columns of the sketch G to $\log(1/\delta)$, which does not effect the $\widetilde{O}(\text{nnz}(A) + \text{poly}(d/\epsilon))$ runtime.

Computing approximations $\widetilde{q_i}$ for q_i. It remains now how to compute the approximate sampling probabilities $\widetilde{q_i}$ for $\Theta(r)$ rows of C that were sampled. Note that to sample an entry, in C, we first sampled the $n \times 1$ submatrix $W^{(i,l)}$ of C which contained it, where the

probability that we sample this submatrix is known to us. Next, if the entry of C was a heavy hitter in $W^{(i,l)}$, we exactly compute the probability that we sample this entry, and sample it with this probability. If the entry j of $W^{(i,l)}$ is not a heavy hitter, we first sample an Ω_t uniformly with probability exactly $1/\eta$. The last step is sampling a coordinate from $W^{(i,l)}_{\Omega_t \setminus H^{(i,l)}}$ via exponential scaling. However, we do not know the exact probability of this sampling, since this will be equal to $|W^{(i,l)}_j|^p / \|W^{(i,l)}_{\Omega_t \setminus H^{(i,l)}}\|_p^p$, and we do not know $\|W^{(i,l)}_{\Omega_t \setminus H^{(i,l)}}\|_p^p$ exactly. Instead, we compute it approximately to error $(1 \pm \epsilon^2)$ as follows. For each $(i,l) \in T$ and $\alpha = 1, 2, \ldots, \Theta(\log(n)/\epsilon^4)$, we compute $Z^{(\alpha)} W^{(i,l)}_{\Omega_t \setminus H^{(i,l)}}$, where $Z \in \mathbb{R}^{1 \times |\Omega_t \setminus H^{(i,l)}|}$ is a vector of p-stable random variables. Again, we use the Indyk median estimator [Ind06], taking the median of these $\Theta(\log(n)/\epsilon^4)$ repetitions, to obtain an estimate of $\|W^{(i,l)}_{\Omega_t \setminus H^{(i,l)}}\|_p^p$ with high probability to $(1 \pm \epsilon^2)$ relative error. Each repetition requires $O(|\Omega_t \setminus H^{(i,l)}|)$ additional time, and since $|\Omega_t \setminus H^{(i,l)}||T| = o(\epsilon^4 n / r^3)$, it follows that the total computational time is at most an additive $o(n)$, thus computing the $\widetilde{q}_i$'s to error $(1 \pm \epsilon^2)$ does not effect the overall runtime.

□

26.10 Missing Proofs from Section 26.5

We first give the proof of the main theorem. The proof relies on Lemma 26.10.2, which the rest of this section will be devoted to proving.

Theorem 26.5.1 *For any constant $q \geq 2$, there is an algorithm which runs in time $O(\sum_{i=1}^{q} \operatorname{nnz}(A_i) + d\,\mathrm{poly}(k/\epsilon))$ and outputs a rank k-matrix B in factored form such that $\|B - A\|_F \leq (1+\epsilon)\,\mathrm{OPT}_k$ with probability $9/10$.*

Proof. By Lemma 26.10.2, we have $(1-\epsilon)\|A-AP\|_F^2 \leq \|M-MP\|_F^2+c \leq (1+\epsilon)\|A-AP\|_F^2$ for all rank k projection matrices P. In particular, we have

$$\min_P (1+\epsilon)\|A-AP\|_F^2 + c = (1+\epsilon)\,\mathrm{OPT}_k^2$$

where the minimum is taken over all rank k projection matrices. The minimizer P on the LHS is given by the projection onto the top k singular space of M. Namely, $MP = MU^\top U$ where U is the top k singular row vectors of M. Thus $\|M - MU^\top U\|_F^2 + c \leq (1+\epsilon)\,\mathrm{OPT}_k^2$. Moreover, we have $\|A - AU^\top U\|_F^2 \leq (1+2\epsilon)(\|M - MU^\top U\|_F^2 + c) \leq (1+4\epsilon)\,\mathrm{OPT}_k^2$. Thus $\|A - AU^\top U\|_F \leq (1+O(\epsilon))\,\mathrm{OPT}_k$ as needed.

For runtime, note that we first must compute $M = (\otimes_{i=1}^q S_i)(A_1 \otimes A_2) = S_1A_1 \otimes \cdots \otimes S_qA_q$. Now S_iA_i can be computed in $O(\mathrm{nnz}(A_i))$ time for each i [CW13]. One all S_iA_i are computed, their Kronecker product can be computed in time $O(qk_1k_2\cdots k_qd) = \mathrm{poly}(kd/\epsilon)$. Given $M \in \mathbb{R}^{k_1\cdots k_q \times d}$, the top k singular vectors U can be computed by computing the SVD of M, which is also done in time $\mathrm{poly}(kd/\epsilon)$. Once U is obtained, the algorithm can terminate, which yields the desired runtime. □

To complete the proof of the main theorem, we will need to prove Lemma 26.10.2. To do this, we begin by introducing two definitions.

Definition 26.10.1. A random matrix S is called a ϵ-subspace embedding for a rank k subspace $\mathcal{V}$ we have simultaneously for all $x \in \mathcal{V}$ that $\|Sx\|_2 = (1 \pm \epsilon)\|x\|_2$.

Definition 26.10.2. A random matrix S satisfies the ϵ-approximate matrix product property if, for any fixed matrices A, B, of the appropriate dimensions, we have $\Pr[\|A^\top S^\top SB - A^\top B\|_F \leq \epsilon\|A\|_F\|B\|_F] \geq 9/10$.

We now show that S is both a subspace embedding and satisfies approximate matrix product, where $S = \otimes_{i=1}^{q} S_i$ and $S_i \in \mathbb{R}^{k_i \times n_i}$ are count-sketch matrices.

Lemma 26.10.1. *If $S = (\otimes_{i=1}^{q} S_i)$ with $S_i \in \mathbb{R}^{k_i \times n_i}$, $k_1 = k_2 = \cdots = k_q = \Theta(qk^2/\epsilon^2)$, then S is an ϵ-subspace embedding for any fixed k dimensional subspace $\mathcal{V} \subset \mathbb{R}^n$ with probability $9/10$, and also satisfies the (ϵ/k)-approximate matrix product property.*

Proof. We first show that S satisfies the $O(\epsilon/k, 1/10, 2)$-JL moment property. Here, the (ϵ, δ, ℓ)-JL moment property means that for any fixed $x \in \mathbb{R}^n$ with $\|x\|_2 = 1$, we have $\mathbb{E}[(\|Sx\|_2^2 - 1)^2] \leq \epsilon^{\ell}\delta$, which will imply approximate matrix product by the results of [KN14].

We prove this by induction on q. Let $\bar{k} = k_1$. First suppose $S = (Q \otimes T)$, where $Q \in \mathbb{R}^{k_1 \times n_1}$ is a count-sketch, and $T \in \mathbb{R}^{k' \times n'}$ is any random matrix which satisfies $\mathbb{E}[\|Tx\|_2^2] = \|x\|_2^2$ ($T \in \mathbb{R}^{k' \times n'}$ is unbiased), and $\mathbb{E}[(\|Tx\|_2 - 1)^2] \leq 1 + c/\bar{k}$ for some value $c < \bar{k}$. Note that both of these properties are satisfied with $c = 4$ if $T \in \mathbb{R}^{k_2 \times n_2}$ is itself a count-sketch matrix [CW13]. Moreover, these are the only properties we will need about T, so we will. We now prove that $\mathbb{E}[\|(S \otimes T)x\|_2^2] = 1$ and $\mathbb{E}[\|(S \otimes T)x\|_2^4] \leq 1 + (c+4)/\bar{k}$ for any unit vector x.

Fix any unit $x \in \mathbb{R}^n$ now (here $n = n_1 n'$), and let $x^j \in \mathbb{R}^{n'}$ be the vector obtained by restricted x to the coordinates $jn_1 + 1$ to $(j+1)n_1$. For any $i \in [k_1], j \in [k']$, let $i_j = (i-1)k' + j$. Let $h_Q(i) \in [k_1]$ denote the row where the non-zero entry in the i-th column is placed in Q. Let $\sigma_Q(i) \in \{1, -1\}$ denote the sign of the entry $Q_{h_Q(i),i}$. Let $\delta_Q(i, j)$

indicate the event that $h_Q(i) = j$. First note that

$$\begin{aligned}
\mathbb{E}\left[\sum_{i,j}((Q \otimes T)x)_{ij}^2\right] &= \mathbb{E}\left[\sum_{i=1}^{k_1}\sum_{j=1}^{k'}\left(\sum_{\tau=1}^{n_1}\delta_Q(\tau,i)\sigma_Q(\tau)(Tx^\tau)_j\right)^2\right] \\
&= \mathbb{E}\left[\sum_{i=1}^{k_1}\sum_{j=1}^{k'}\sum_{\tau=1}^{n_1}\delta_Q(\tau,i)(Tx^\tau)_j^2\right] \\
&= \mathbb{E}\left[\sum_{\tau=1}^{n_1}\sum_{i=1}^{k_1}\sum_{j=1}^{k'}\delta_Q(\tau,i)(Tx^\tau)_j^2\right] \\
&= \mathbb{E}\left[\sum_{\tau=1}^{n_1}\|Tx^\tau\|_2^2\right] \\
&= \|x\|_2^2
\end{aligned}$$

Where the last equality follows because count-sketch T is unbiased for the base case, namely that $\mathbb{E}[\|Tx\|_2^2] = \|x\|_2^2$ for any x [Woo14b], or by induction. We now compute the second moment,

$$\begin{aligned}
\mathbb{E}\left[\left(\sum_{i,j}((Q \otimes T)x)_{ij}^2\right)^2\right] &= \mathbb{E}\left[\left(\sum_{i,j}\left(\sum_{\tau=1}^{n_1}\delta_Q(\tau,i)\sigma_Q(\tau)(Tx^\tau)_j\right)^2\right)^2\right] \\
&= \mathbb{E}\left[\left(\sum_{i,j}\sum_{\tau_1,\tau_2}^{n_1}\delta_Q(\tau_1,i)\sigma_Q(\tau_1)(Tx^{\tau_1})_j\delta_Q(\tau_2,i)\sigma_Q(\tau_2)(Tx^{\tau_2})_j\right)^2\right] \\
&= \sum_{\tau_1,\tau_2,\tau_3,\tau_4}^{n_1}\mathbb{E}\left[\left(\sum_{i,j}\delta_Q(\tau_1,i)\sigma_Q(\tau_1)(Tx^{\tau_1})_j\delta_Q(\tau_2,i)\sigma_Q(\tau_2)(Tx^{\tau_2})_j\right)\right. \\
&\quad \left.\cdot\left(\sum_{i,j}\delta_Q(\tau_3,i)\sigma_Q(\tau_3)(Tx^{\tau_3})_j\delta_Q(\tau_4,i)\sigma_Q(\tau_4)(Tx^{\tau_4})_j\right)\right].
\end{aligned}$$

We now analyze the above expectation. There are several cases for the expectation of each

term. First, we bound the sum of the expectations when $t_1 = t_2 = t_3 = t_4$ by

$$\begin{aligned}
&\sum_{\tau=1}^{n_1} \mathbb{E}\left[\left(\sum_{i,j} \delta_Q(\tau,i)\sigma_Q(\tau)(Tx^\tau)_j \delta_Q(\tau,i)\sigma_Q(\tau)(Tx^\tau)_j\right)\right. \\
&\left.\cdot\left(\sum_{i,j} \delta_Q(\tau,i)\sigma_Q(\tau)(Tx^\tau)_j \delta_Q(\tau,i)\sigma_Q(\tau)(Tx^\tau)_j\right)\right] \\
\leq &\sum_{\tau=1}^{n_1} \mathbb{E}\left[\|Tx^\tau\|_2^4\right] = 1 + c/\bar{k}
\end{aligned}$$

Where the last equation follows from the variance of count-sketch [CW13] for the base case, or by induction for $q \geq 3$. We now bound the sum of the expectations when $t_1 = t_2 \neq t_3 = t_4$ by

$$\begin{aligned}
&\sum_{\tau_1 \neq \tau_2} \mathbb{E}\left[\left(\sum_{i,j} \delta_Q(\tau_1,i)\sigma_Q(\tau_1)(Tx^{\tau_1})_j \delta_Q(\tau_1,i)\sigma_Q(\tau_1)(Tx^{\tau_1})_j\right)\right. \\
&\left.\cdot\left(\sum_{i,j} \delta_Q(\tau_2,i)\sigma_Q(\tau_2)(Tx^{\tau_2})_j \delta_Q(\tau_2,i)\sigma_Q(\tau_2)(Tx^{\tau_2})_j\right)\right] \\
&\leq \sum_{\tau_1 \neq \tau_2} \mathbb{E}[\|Tx^{\tau_1}\|_2^2 \|Tx^{\tau_2}\|_2^2/k_1] \\
&\leq \mathbb{E}[\|Tx\|_2^4/k_1] \leq (1 + c/\bar{k})/k_1.
\end{aligned}$$

We can similarly bound the sum of the terms with $t_1 = t_3 \neq t_2 = t_4$ and $t_1 = t_4 \neq t_3 = t_2$ by $(1 + c/\bar{k})/k_1$, giving a total bound on the second moment of

$$\mathbb{E}[\|(Q \otimes T)x\|_2^4] \leq 1 + c/\bar{k} + 3(1 + c/\bar{k})/k_1) \leq 1 + (4 + c)/\bar{k}$$

since any term with a $t_i \notin \{t_1, t_2, t_3, t_4\} \setminus \{t_i\}$ immediately has expectation 0. By induction, it follows that $\mathbb{E}[(\otimes_{i=1}^q S_i)x\|_2^2] = 1$ for any unit x, and $\mathbb{E}[(\otimes_{i=1}^q S_i)x\|_2^4] \leq 1 + (4q + c)/\bar{k}$, where c is the constant from the original variance of count-sketch. Setting $\bar{k} = k_1 = \cdots = k_q = \Theta(qk^2/\epsilon^2)$ with a large enough constant, this completes the proof that $S = (\otimes_{i=1}^q S_i)$

has the $O(\epsilon/k, 1/10, 2)$-JL moment property. Then by Theorem 21 of [KN14], we obtain the approximate matrix product property:

$$\Pr[\|A^\top S^\top SB - A^\top B\|_F \leq O(\epsilon/k)\|A\|_F\|B\|_F] \geq 9/10$$

for any two matrices A, B. Letting $A = B^\top = U$ where $U \in \mathbb{R}^{n\times k}$ is a orthogonal basis for any k-dimensional subspace $\mathcal{V} \subset \mathbb{R}^n$, it follows that

$$\|U^\top S^\top SU - I_k\|_F \leq O(\epsilon/k)\|U\|_F^2 \leq O(\epsilon),$$

where the last step follows because U is orthonormal, so $\|U\|_F^2 = k$. Since the Frobenius norm upper bounds the spectral norm $\|\cdot\|_2$, we have $\|U^\top S^\top SU - I_k\|_2 \leq O(\epsilon)$, from which it follows that all the eigenvalues of $U^\top S^\top SU$ are in $(1 - O(\epsilon), 1 + O(\epsilon))$, which implies $\|SUx\|_2 = (1 \pm O(\epsilon))\|x\|_2$ for all $x \in \mathbb{R}^n$, so for any $y \in \mathcal{V}$, let x_y be such that $y = Ux_y$, and then $\|Sy\|_2 = \|SUx_y\|_2 = (1 \pm O(\epsilon))\|x_y\|_2 = (1 \pm O(\epsilon))\|Ux_y\|_2 = (1 \pm O(\epsilon))\|y\|_2$, which proves that S is a subspace embedding for $\mathcal{V}$ (not the second to last inequality holds because U is orthonormal). □

Finally, we are ready to prove Lemma 26.10.2.

Lemma 26.10.2. *Let $S = (\otimes_{i=1}^q S_i)$ with $S_i \in \mathbb{R}^{k_i\times n_i}$, $k_1 = k_2 = \cdots = k_q = \Theta(qk^2/\epsilon^2)$. Then with probability $9/10$ SA is a Projection Cost Preserving Sketch (PCP) for A, namely for all rank k orthogonal projection matrix $P \in \mathbb{R}^{d\times d}$,*

$$(1 - \epsilon)\|A - AP\|_F^2 \leq \|SA - SAP\|_F^2 + c \leq (1 + \epsilon)\|A - AP\|_F^2$$

where $c \geq 0$ is some fixed constant independent of P (but may depend on A and SA).

Proof. To demonstrate that SA is a PCP, we show that the conditions of Lemma 10 of [CEM+15] hold, which imply this result. Our result follows directly from Theorem 12 of [CEM+15]. Note that all that is needed (as discussed below the theorem) for the proof is that S is an ϵ-subspace embedding for a fixed k-dimensional subspaces, and that S satisfies the $(\epsilon/\sqrt{k})$ approximate matrix product property. By Lemma 26.10.1, we have both ϵ-subspace embedding for S as well as a stronger (ϵ/k) approximate matrix product property. Thus Theorem 12 holds for the random matrix S when $k_1 = k_2 = \cdots = k_q = \Theta(qk^2/\epsilon^2)$, which completes the proof.

□

26.11 Entry-wise Norm Low T-rank Approximation

We now demonstrate our results for low trank approximation of arbitrary input matrices. Specifically, we study the following problem, defined in [VL00]: given $A \in \mathbb{R}^{n^2 \times n^2}$, the goal is to output a trank-k matrix $B \in \mathbb{R}^{n^2 \times n^2}$ such that

$$\|B - A\|_\xi \leq \alpha \cdot \mathrm{OPT}\,. \tag{26.1}$$

for some $\alpha \geq 1$, where $\mathrm{OPT} = \min_{\mathrm{trank}-k\ A'} \|A' - A\|_\xi$,, where the trank of a matrix B is defined as the smallest integer k such that B can be written as a summation of k matrices, where each matrix is the Kronecker product of q matrices with dimensions $n \times n$: $B = \sum_{i=1}^{k} U_i \otimes V_i$, where $U_i, V_i \in \mathbb{R}^{n \times n}$.

Using Lemma 26.8.1, we can rearrange the entries in $A \in \mathbb{R}^{n^2 \times n^2}$ to obtain $\overline{A} \in \mathbb{R}^{n^2 \times n^2}$, where the $(i + n(j-1))$'th row of $\bar{A}$ is equal to $vec((A_1)_{i,j} A_2)$, and also vectorize the matrix $U_i \in \mathbb{R}^{n \times n}$ and $V_i \in \mathbb{R}^{n \times n}$ to obtain vectors $u_i \in \mathbb{R}^{n^2}, v_i \in \mathbb{R}^{n^2}$. Therefore, for any entry-wise

norm ξ we have

$$\left\|\sum_{i=1}^{k} U_i \otimes V_i - A\right\|_{\xi} = \left\|\sum_{i=1}^{k} u_i v_i^{\top} - \overline{A}\right\|_{\xi}$$

Lemma 26.11.1 (Reshaping for Low Rank Approximation)**.** *There is a one-to-one mapping* $\pi : [n] \times [n] \times [n] \times [n] \to [n^2] \times [n^2]$ *such that for any pairs* $(U, u) \in \mathbb{R}^{n \times n} \times \mathbb{R}^{n^2}$ *and* $(V, v) \in \mathbb{R}^{n \times n} \times \mathbb{R}^{n^2}$*, if* $U_{i_1, j_1} = u_{i_1 + n(j_1 - 1)}$ *and* $V_{i_1, j_1} = v_{i_1 + n(j_1 - 1)}$*, then we have for* i_1, i_2, j_1, j_2

$$(U \otimes V)_{i_1 + n(i_2 - 1), j_1 + n(j_2 - 1)} = (u \cdot v^{\top})_{\pi(i_1, i_2, j_1, j_2)}$$

where $U \otimes V \in \mathbb{R}^{n^2 \times n^2}$ *and* $uv^{\top} \in \mathbb{R}^{n^2 \times n^2}$*.*

Proof. We have

$$\begin{aligned}(U \otimes V)_{i_1 + n(i_2 - 1), j_1 + n(j_2 - 1)} &= U_{i_1, j_1} V_{i_2, j_2} \\ &= u_{i_1 + n(j_1 - 1)} \cdot v_{i_2 + n(j_2 - 1)} \\ &= (uv^{\top})_{i_1 + n(j_1 - 1), i_2 + n(j_2 - 1)}\end{aligned}$$

where the first step follows from the definition of $\otimes$ product, the second step follows from the connection between U, V and u, v, the last step follows from the outer product. $\square$

Therefore, instead of using trank to define low-rank approximation of the $\otimes$ product of two matrices, we can just use the standard notion of rank to define it since both B and A' can be rearranged to have rank k.

Definition 26.11.1 (Based on Standard Notion of Rank)**.** Given two matrices $A_1, A_2 \times \mathbb{R}^{n \times n}$, let $\overline{A} \in \mathbb{R}^{n^2 \times n^2}$ denote the re-shaping of $A_1 \otimes A_2$. The goal is to output a rank-k matrix $\overline{B}$ such that

$$\|\overline{B} - \overline{A}\|_{\xi} \leq \alpha \, \mathrm{OPT}_{\xi, k}$$

where $\mathrm{OPT}_{\xi, k} = \min_{\mathrm{rank}-k \ \overline{A}'} \|\overline{A}' - \overline{A}\|_{\xi}$.

In other words, $\overline{B}$ can be written as $\overline{B} = \sum_{i=1}^{k} u_i v_i^\top$ where u_i, v_i are length n^2 vectors.

Combining the low-rank reshaping Lemma 26.11.1 with the main input-sparsity low-rank approximation of [CW13], we obtain our Frobenius norm low rank approximation result.

Theorem 26.11.2 (Frobenius norm low rank approximation, $p = 2$)**.** *For any $\epsilon \in (0, 1/2)$, there is an algorithm that runs in $n^2 \operatorname{poly}(k/\epsilon)$ and outputs a rank-k matrix $\overline{B}$ such that $\|\overline{B} - \overline{A}\|_F \leq (1+\epsilon) \operatorname{OPT}_{F,k}$ holds with probability at least $9/10$, where OPT_p is cost achieved by best rank-k solution under the ℓ_p-norm.*

Similarly, using the main ℓ_p low rank approximation algorithm of [SWZ17], we have

Theorem 26.11.3 (Entry-wise ℓ_p-norm low rank approximation, $1 \leq p \leq 2$)**.** *There is an algorithm that runs in $n^2 \operatorname{poly}(k)$ and outputs a rank-k matrix $\overline{B}$ such that $\|\overline{B} - \overline{A}\|_p \leq \operatorname{poly}(k \log n) \operatorname{OPT}_{p,k}$ holds with probability at least $9/10$, where OPT_p is cost achieved by best rank-k solution under the ℓ_p-norm.*

Applying the bi-criteria algorithm of [CGK+17c] gives us:

Theorem 26.11.4 (General $p > 1$, bicriteria algorithm)**.** *There is an algorithm that runs in $\operatorname{poly}(n, k)$ and outputs a rank-$\operatorname{poly}(k \log n)$ matrix $\overline{B}$ such that $\|\overline{B} - \overline{A}\|_p \leq \operatorname{poly}(k \log n) \operatorname{OPT}_p$ holds with probability at least $9/10$, where $\operatorname{OPT}_{p,k}$ is cost achieved by best rank-k solution under the ℓ_p-norm.*

Finally using the low-rank approximation algorithm for general loss functions given in [SWZ18], we obtain a very general result. The parameters for the loss function described in the following theorem are discussed in Section 26.12.

Theorem 26.11.5 (General loss function g)**.** *For any function g that satisfies Definition 26.12.1, 26.12.2, 26.12.3, there is an algorithm that runs in $O(n^2 \cdot T_{\mathrm{reg},g,n^2,k,n^2})$ time and outputs a* rank-$O(k \log n)$ *matrix $\overline{B} \in \mathbb{R}^{n^2 \times n^2}$ such that*

$$\|\overline{B} - \overline{A}\|_g \leq \mathrm{ati}_{g,k} \cdot \mathrm{mon}_g \cdot \mathrm{reg}_{g,k} \cdot O(k \log k) \cdot \mathrm{OPT}_{g,k},$$

holds with probability $1 - 1/\operatorname{poly}(n)$.

Hence, overall, the strategy is to first reshape $A = A_1 \otimes A_2$ into $\bar{A}$, then compute $\bar{B} = \sum_{i=1}^k u_i v_i^\top$ using any of the above three theorems depending on the desired norm, and finally reshape u_i and v_i back to $U_i \in \mathbb{R}^{n \times n}$ and $V_i \in \mathbb{R}^{n \times n}$. It is easy to verify that the guarantees from Theorems 26.11.5, 26.11.3, 26.11.2 are directly transferable to the guarantee of the trank $-k$ approximation shown in Eq 26.1.

26.12 Properties for General Loss Functions for Low trank Approximation

We re-state three general properties (defined in [SWZ18]), the first two of which are structural properties and are necessary and sufficient for obtaining a good approximation from a small subset of columns. The third property is needed for efficient running time.

Definition 26.12.1 (Approximate triangle inequality)**.** For any positive integer n, we say a function $g(x) : \mathbb{R} \to \mathbb{R}_{\geq 0}$ satisfies the $\mathrm{ati}_{g,n}$-approximate triangle inequality if for any $x_1, x_2, \cdots, x_n \in \mathbb{R}$ we have

$$g\left(\sum_{i=1}^n x_i\right) \leq \mathrm{ati}_{g,n} \cdot \sum_{i=1}^n g(x_i).$$

Definition 26.12.2 (Monotone property)**.** For any parameter $\mathrm{mon}_g \geq 1$, we say function $g(x) : \mathbb{R} \to \mathbb{R}_{\geq 0}$ is mon_g-monotone if for any $x, y \in \mathbb{R}$ with $0 \leq |x| \leq |y|$, we have $g(x) \leq \mathrm{mon}_g \cdot g(y)$.

Definition 26.12.3 (Regression property)**.** We say function $g(x) : \mathbb{R} \to \mathbb{R}_{\geq 0}$ has the $(\mathrm{reg}_{g,d}, T_{\mathrm{reg},g,n,d,m})$-regression property if the following holds: given two matrices $A \in \mathbb{R}^{n \times d}$ and $B \in \mathbb{R}^{n \times m}$, for each $i \in [m]$, let OPT_i denote $\min_{x \in \mathbb{R}^d} \|Ax - B_i\|_g$. There is an algorithm that runs in $T_{\mathrm{reg},g,n,d,m}$ time and outputs a matrix $X' \in \mathbb{R}^{d \times m}$ such that

$$\|AX'_i - B\|_g \leq \mathrm{reg}_{g,d} \cdot \mathrm{OPT}_i, \forall i \in [m]$$

and outputs a vector $v \in \mathbb{R}^d$ such that

$$\mathrm{OPT}_i \leq v_i \leq \mathrm{reg}_{g,d} \cdot \mathrm{OPT}_i, \forall i \in [m].$$

The success probability is at least $1 - 1/\operatorname{poly}(nm)$.

Chapter 27

Dynamic k-means Clustering

We consider the k-means clustering problem in the dynamic streaming setting, where points from a discrete Euclidean space $\{1, 2, \ldots, \Delta\}^d$ can be dynamically inserted to or deleted from the dataset. For this problem, we provide a one-pass coreset construction algorithm using space $\widetilde{O}(k \cdot \mathrm{poly}(d, \log \Delta))$, where k is the target number of centers. To our knowledge, this is the first dynamic geometric data stream algorithm for k-means using space polynomial in dimension and nearly optimal (linear) in k.

This part is based upon the following previous publication

  Nearly Optimal Dynamic k-Means Clustering for High-Dimensional Data.
  Manuscript 2018 [HSYZ18]

27.1 Introduction

Clustering is one of the central problems in unsupervised learning. The idea is to partition data points into clusters in the hope that points in the same cluster are similar to each other and points in different clusters are dissimilar. One of the most important approaches to clustering is *k-means*, which has been extensively studied for more than 60 years and has a wide range of applications (see e.g. [Jai10] for a survey). Given a set of points $Q \subset \mathbb{R}^d$, the k-means problem asks for a set of k *centers* $Z \subset \mathbb{R}^d$ such that the sum of squares of distances between data points to their closest centers is minimized, i.e., it tries to solve $\min_{Z \subset \mathbb{R}^d, |Z|=k} \text{cost}(Q, Z)$, where $\text{cost}(Q, Z)$ is a cost function defined as:

$$\text{cost}(Q, Z) := \sum_{q \in Q} \min_{z \in Z} \text{dist}^2(q, z).$$

Here $\text{dist}(\cdot, \cdot)$ stands for the Euclidean distance.

A major challenge in dealing with massive datasets is that the entire input data can be too large to be stored. A standard model of study in such settings is the *streaming* model, where data points arrive and are processed one at a time, and only a small amount of useful information (i.e., a *sketch*) about the data is maintained. See e.g. [Mut05b] for an introduction to the streaming model.

In this paper we study the k-means problem over *dynamic data streams* [Ind04], where data points from a discrete space $\{1, 2, \ldots, \Delta\}^d$ can be either inserted to or deleted from the dataset. A standard approach to solving k-clustering problems like k-means and k-median in the streaming setting is to maintain an ϵ-*coreset*, which is a small number of (weighted) points whose cost with respect to any k centers is a $(1 + \epsilon)$-approximation to the cost of the entire dataset on the same k centers. As a consequence, at the end of the stream, we

only need to find an approximate k-means solution on the coreset, which is automatically an approximate solution on the entire dataset. Hence our goal is to design an efficient method to maintain an ϵ-coreset over a dynamic data stream using as small space as possible.

27.1.1 Our Result

Theorem 27.1.1 (Main theorem, restatement of Theorem 27.6.22 in Section 27.6)**.** *Let $\epsilon \in (0, 1/2)$, $k, \Delta \in \mathbb{N}_+$, and $L = \log \Delta$. For dynamic data stream consisting of insertions and deletions of points in $[\Delta]^d$, there is an algorithm which uses a single pass over the stream and on termination outputs a weighted set S with a positive weight for each point therein, such that with probability at least 0.9, S is an ϵ-coreset for k-means of size $O(k\epsilon^{-2}d^4L^2 \log(kdL))$. The algorithm uses $\widetilde{O}(k) \cdot \mathrm{poly}(d, L, \epsilon^{-1})$ bits in the worst case.*

To our knowledge, this is the first algorithm for k-means in dynamic data streams that uses space *polynomial in data dimension d* and *nearly optimal (linear)*[1] *in the number of clusters k*. Previous algorithms for streaming k-means either require space exponential in d or only work for insertion-only streams.[2] See Section 27.1.3 and Section 27.7 for detailed discussions of previous results.

27.1.2 Our Techniques

At a high level our algorithm is based on a framework called *sensitivity sampling*, which was proposed by [FL11]. For a set $Q \subseteq [\Delta]^d$, the *sensitivity* of every point $q \in Q$ is

[1] It is easy to see that k points are needed in a coreset – when there are only k points in the dataset, the optimal k-means cost is 0, so a coreset has to contain all k points.

[2] It is also possible to obtain an $\widetilde{O}(k^2 \cdot \mathrm{poly}(d))$ space algorithm for dynamic streams by combining the techniques from [Che09] and [BFL+17].

defined as

$$s(q) := \max_{Z \subset \mathbb{R}^d, |Z|=k} \frac{\mathrm{dist}^2(q, Z)}{\sum_{p \in Q} \mathrm{dist}^2(p, Z)}.$$

Namely, $s(q)$ represents how "sensitive" the cost can be to the removal of point q. A crucial result shown by [FL11, BFL16] is that once we know a good *upper bound* on each point's sensitivity, there is a sampling method to construct an ϵ-coreset. Specifically, if we know an upper bound $s'(q) \geq s(q)$ for each $q \in Q$, we can sample q with probability $s'(q)/(\sum_{p \in Q} s'(p))$. Let R be a set of i.i.d. samples from this procedure with $|R| \geq \widetilde{\Omega}\left(\sum_{q \in Q} s'(q)/\epsilon^2\right)$, and each sample q is assigned a weight $\frac{\sum_{p \in Q} s'(p)}{|R| s'(q)}$. Then with high probability R is an ϵ-coreset for Q. Note that if $\sum_{q \in Q} s'(q) = \widetilde{O}(k \cdot \mathrm{poly}(d))$, then an $\widetilde{O}(k \cdot \mathrm{poly}(d))$-size ϵ-coreset can be constructed in this way. The formal description of this result is given in Theorem 27.2.1.

We give an efficient method to obtain sensitivity upper bounds $s'(\cdot)$ such that: (i) $\sum_{q \in Q} s'(q)$ is small, (ii) we can implement the sensitivity sampling procedure in the dynamic streaming setting. Then we are able to construct a coreset according to the previous paragraph.

The key intuition in our sensitivity estimation is the following. Imagine that there is a small region that is very dense, i.e., it contains a lot of points. Then the sensitivity of every point in that region must be low, because that point can be well represented by other points in the same small region. Therefore, the problem of finding sensitivity upper bound for a point boils down to figuring out the "right" region this point belongs to that can be considered "dense." Intuitively the sensitivity of this point depends on the size of this dense region – the smaller the size, the smaller the sensitivity.

We make this intuition formal by using a hierarchical grid structure similar to [FS05, BFL+17]. This structure is illustrated in Figure 27.1. The top-level (level 0) grid consists of

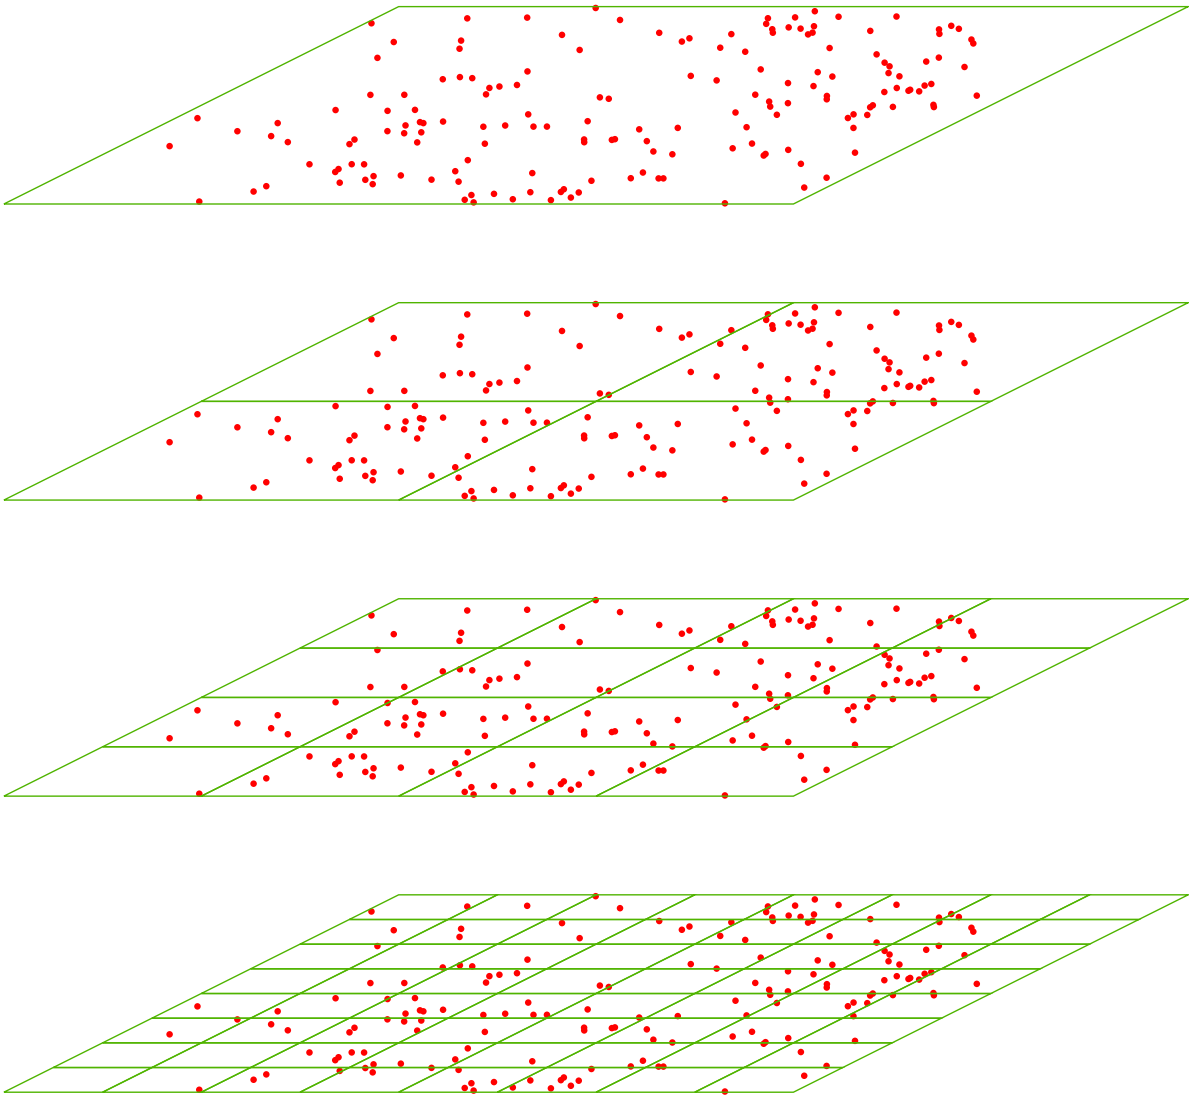

Figure 27.1: The grid structure over the point set. From top to bottom, three levels of grids are shown. Each cell splits into 2^d cells in the next level.

cells that are d-dimensional cubes of side-length Δ, and each cell in level $i-1$ splits into 2^d cells in level i. Each cell in level i has side-length $\Delta/2^i$. For a cell in level i, we say that it is *heavy* if it contains at least $T_i = \Theta\left(\frac{d^2}{k} \cdot \frac{\mathrm{OPT}}{(\Delta/2^i)^2}\right)$ points in Q, where OPT is the optimal cost of the k-means problem.[3] Since $T_i > T_{i-1}$, we know that if a cell in level i is heavy, then its parent cell in level $i-1$ is heavy as well. Therefore the set of all heavy cells in all levels form a tree. Now for a point $p \in Q$, denote by $c_i(p)$ the cell in level i that contains p, and then define j to be the smallest level index such that $c_j(p)$ is not heavy; then we show an upper bound on the sensitivity $s(p)$ solely based on this index number j, namely $s(p) \le s'(p) = \Theta(d^3/T_j)$. Furthermore, we prove that the sum of our sensitivity upper bounds is small: $\sum_{p\in Q} s'(p) = O\left(kd^3 \log \Delta\right)$, which satisfies our requirement. To establish these bounds we need the total number of heavy cells to be small, for which we apply a random shift of grid at the beginning, as illustrated in Figure 27.2.

To implement the above sensitivity sampling method in the dynamic streaming setting when the dataset is updated by insertions and deletions of points, the key difficulties are: 1) we do not know the value of OPT, and it changes when the underlying dataset is updated; 2) we need to compute the sensitivity upper bounds and to sample points at the same time using limited space.

Let us first assume OPT is known and give an algorithm to implement our sensitivity sampling procedure in the dynamic streaming setting. Our algorithm makes crucial use of the *k-set* data structure in [Gan05] for counting *distinct elements* in a dynamic stream. The k-set data structure ensures that if the number of distinct elements is at most some

[3] We assume for now that we know OPT. Our actual algorithm uses exponential search to guess the value of OPT.

predetermined parameter, it will return all distinct elements and their frequencies; otherwise it will return **FAIL**. We summarize its guarantee in Lemma 27.6.1. Note that in order to implement sensitivity sampling, we need to know which cells are heavy. Our algorithm dynamically tracks all heavy cells, using the k-set structure as a building block. Then the sensitivity sampling method has two stages: first sample a level i (with an appropriate probability for each level), and then uniformly sample a point from all points associated with level i, i.e., all points p such that $c_i(p)$ is not heavy and $c_{i-1}(p)$ is heavy. (Note that for all points associated with level i, they have the same sensitivity upper bounds, which means uniformly sampling a point from them is enough.) In order to do uniform sampling, we also maintain for each level i a uniformly random subset of points associated with i. Therefore it suffices to choose a point uniformly at random from this subset once i is chosen.

For the issue of not knowing OPT, we run in parallel multiple copies of our sampling algorithm for different guesses of OPT: $1, 2, 4 \ldots, \Delta^d \cdot d\Delta$. Our sampling algorithm ensures that when the guessed value is less than OPT but not too far away, the required space is small. For other guesses, the required space might be a lot, but since we have a space budget, our algorithm can return **FAIL** when the space runs out. Since at least one guess is accurate, at least one copy of the algorithm will succeed and output a small ϵ-coreset.

27.1.3 Related Work

It is well known that exactly solving k-means is NP-hard even for $k = 2$ or $d = 2$ [ADHP09, MNV09]. The most successful algorithm used in practice is Lloyd's algorithm, which is also known as "the k-means method" [Llo82]. Because of the NP-hardness, various attempts were made on approximation algorithms. [KMN+02] proved that a very simple

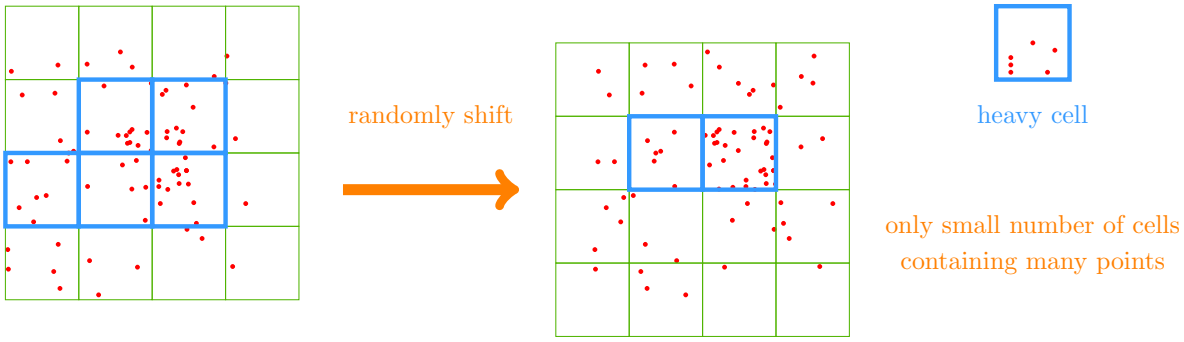

Figure 27.2: Random shift of grid brings down the number of heavy cells. In the left panel, we have a bad alignment of points and grids such that many cells contain lots of points. In the right panel, after the random shift, only two cells contain many points.

local search heuristic achieves $(9+\epsilon)$-approximation in polynomial time for any fixed $\epsilon > 0$. When d is a constant [FRS16, CAKM16] or k is a constant [FMS07, KSS10, FL11], $(1+\epsilon)$-approximation can be achieved in polynomial time.

There is a line of work studying k-means and k-median in insertion-only streams, e.g., [BS80a, GMMO00, COP03, BDMO03, AHPV04, HPM04, HPK05, Che09, FL11, FS12, AMR+12, BFL16]. There also have been a lot of interests in dynamic streaming algorithms for other problems, e.g. [BYJK+02, FKM+05, Bas08, KL11, AGM12a, AGM12b, GKP12, GKK12, AGM12b, BKS12a, CMS13, AGM13, Moi14a, BGS15, BHNT15, BS16, ACD+16, ADK+16, BWZ16, KLM+17, SWZ17, SWZ19b]. In addition, k-means and k-median were studied in various different settings, e.g., [CCGG98, IP11, BIRW16, BCMN14, SW18].

The most relevant papers are [FS05, FL11, BFL16, BFL+17]. [FS05] designed an algorithm to maintain an ϵ-coreset of size $k\epsilon^{-O(d)}$ for k-means and k-median. [FL11] introduced the sensitivity sampling framework for coreset construction, and their approach was further improved by [BFL16], but both of them only work for insertion-only streams and do

not apply to dynamic streams. [BFL+17] focused on the k-median problem and constructed a coreset of size $O(k \cdot \text{poly}(d, \log \Delta))$ in the dynamic streaming setting, but their technique heavily relies on k-median and cannot be extended to k-means. In Section 27.7 we explain in detail the limitations of previous approaches.

27.1.4 Roadmap

In Section 27.2, we introduce necessary notation and preliminaries. In Section 27.3, we give the offline version of our algorithm. Due to the page limit, missing proofs in Section 27.3 are given in Section 27.5, and we present our dynamic streaming algorithm and its analysis in Section 27.6.

27.2 Preliminaries

Notation. For $n \in \mathbb{N}_+$, let $[n] := \{1, 2, \ldots, n\}$. We define $\widetilde{O}(f)$ to be $O\left(f \cdot \log^{O(1)}(f)\right)$. For any $x \in \mathbb{R}_{\geq 0}, \epsilon \in (0,1)$, we use $(1 \pm \epsilon) \cdot x$ to denote the interval $((1-\epsilon) \cdot x, (1+\epsilon) \cdot x)$. For any $x \in \mathbb{R}$ and $a \in \mathbb{R}_{>0}$, $x \pm a$ denotes the interval $(x - a, x + a)$.

We denote by $\mathrm{dist}(\cdot, \cdot)$ the Euclidean distance in $\mathbb{R}^d$, i.e., for $p, q \in \mathbb{R}^d$, $\mathrm{dist}(p, q) := \|p - q\|_2$. For sets $P, Q \subseteq \mathbb{R}^d$ and a point $p \in \mathbb{R}^d$, we define $\mathrm{dist}(p, Q) = \mathrm{dist}(Q, p) := \min_{q \in Q} \mathrm{dist}(p, q)$ and $\mathrm{dist}(P, Q) := \min_{p \in P, q \in Q} \mathrm{dist}(p, q)$. For any two sets $Q, Z \subseteq \mathbb{R}^d$, we define $\mathrm{cost}(Q, Z) := \sum_{q \in Q} \mathrm{dist}^2(q, Z)$. We define $\mathrm{diam}(Q)$ to be Q's diameter, i.e., $\mathrm{diam}(Q) := \max_{p,q \in Q} \mathrm{dist}(p, q)$.

The dynamic streaming model. We consider the *dynamic streaming model*, defined below.

Definition 27.2.1 (Dynamic streaming model)**.** Let $Q \subseteq [\Delta]^d$ initially be an empty set. In the dynamic streaming model, there is a stream of update operations such that the t^{th} operation has the form $(p_t, \pm)$ which indicates that a point $p_t \in [\Delta]^d$ is inserted to or deleted from the set Q, where $+$ denotes insertion and $-$ denotes deletion. There is no invalid deletion during the stream.[4] An algorithm is allowed a single pass over the stream. At the end of the stream, the algorithm stores some information regarding Q. The space complexity of an algorithm in this model is defined as the total number of bits used by the algorithm during the stream.

[4] At any time during the stream, for any point $p \in [\Delta]^d$, the number of deletions of p so far is always no more than the number of insertions of p.

The goal of an algorithm in this model is to store some information which can be used for a certain computation task, while using as small space as possible. Although optimizing the running time is not required in this model, the algorithm in the current paper is actually efficient for each update.

In this paper we suppose that any two points in Q have different locations[5], i.e., Q is not a multiset. Our algorithm can be easily extended to allow multiple copies of a point by blowing up the total space by an $O(\log M)$ factor, where M is an upper bound on the number of copies.

k-means clustering. Now we introduce the *k-means clustering problem* and the notion of *coreset*.

Definition 27.2.2 (k-means clustering)**.** Given a point set $Q \subseteq [\Delta]^d$ and a parameter $k \in \mathbb{N}_+$ for the target number of centers, the goal of k-means clustering is to find a set of k points $Z \subseteq \mathbb{R}^d$ such that the objective function, $\mathrm{cost}(Q, Z) := \sum_{q \in Q} \mathrm{dist}^2(q, Z)$, is minimized. Each point in Z is called a *center*. OPT is defined to be the optimal cost of the k-means clustering problem.

However, solving the k-means problem exactly is NP-hard [ADHP09]. Oftentimes, we only need a good approximation. For the purpose of finding an approximate solution, an important concept is *coreset*, which is a small subset of (weighted) points whose k-means solution is a good approximate solution for the entire dataset. The formal definition is the following:

[5] At the end of the stream, for any point $p \in [\Delta]^d$, the number of insertions of p is at most one more than the number of deletions of p.

Definition 27.2.3 (Coreset for k-means)**.** Given $Q \subseteq [\Delta]^d$, $k \in \mathbb{N}_+$ and $\epsilon > 0$, a set of point-weight pairs $S = \{(s_1, w_1), (s_2, w_2), \ldots, (s_m, w_m)\} \subset [\Delta]^d \times \mathbb{R}_{>0}$ is an *ϵ-coreset* for Q, where w_i is the weight of s_i, if S satisfies

$$\forall Z \subset \mathbb{R}^d, |Z| = k : \left| \operatorname{cost}(S, Z) - \operatorname{cost}(Q, Z) \right| \leq \epsilon \cdot \operatorname{cost}(Q, Z),$$

where $\operatorname{cost}(S, Z) := \sum_{i=1}^m w_i \operatorname{dist}^2(s_i, Z)$. The size of the coreset is $|S|$.

The main problem studied in this paper is how to construct a small coreset for k-means over a dynamic data stream. The formal description is the following.

Definition 27.2.4 (Coreset for k-means over a dynamic stream)**.** Given a point set $Q \subseteq [\Delta]^d$ described by a dynamic stream of operations (Definition 27.2.1), a parameter $k \in \mathbb{N}_+$ for the target number of centers, and an error parameter $\epsilon \in (0, 0.5)$. The goal is to design an algorithm in the dynamic streaming model which can with probability at least 0.9 output a small size k-means ϵ-coreset (Definition 27.2.3) for Q using as small space as possible.

Sensitivity sampling based coreset construction. Let us briefly review the coreset construction framework proposed by [FL11, BFL16]. Given $Q \subseteq [\Delta]^d$ and $k \in \mathbb{N}_+$, the *sensitivity* of a point $p \in Q$ is defined as:

$$s(p) = \max_{Z \in \mathbb{R}^d, |Z| = k} \frac{\operatorname{dist}^2(p, Z)}{\sum_{q \in Q} \operatorname{dist}^2(q, Z)}.$$

The following theorem gives guarantee of a sensitivity sampling based coreset construction.

Theorem 27.2.1 ([FL11, BFL16])**.** *Given a set of points $Q \subseteq [\Delta]^d$ and a parameter k, let $s(p)$ denote the sensitivity of each point $p \in Q$. For each $p \in Q$, let $s'(p)$ be an upper*

bound on the sensitivity of p, i.e., $s'(p) \geq s(p)$, and let $t' = \sum_{p \in Q} s'(p)$. Consider a multiset S of m i.i.d. samples from Q, where each sample chooses $p \in Q$ with probability $s'(p)/t'$. For each sampled point p, a weight $w(p) \in (1 \pm \epsilon/2) \cdot t'/(ms'(p))$ is associated with p. If $m \geq \Omega(t'\epsilon^{-2}(\log |Q| \log t' + \log(1/\delta)))$, then with probability at least $1 - \delta$, $\{(p, w(p)) \mid p \in S\}$ is an ϵ-coreset (Definition 27.2.3) for Q.

According to the above theorem, if we can find a good sensitivity upper bound $s'(p)$ for each point p, then we are able to construct a coreset with size nearly linear in $t' = \sum_p s'(p)$. In section 27.3, we give an offline algorithm which can estimate a good sensitivity upper bound for each point, which readily implies an efficient offline coreset construction algorithm. In Section 27.6, we show how to implement this sensitivity sampling procedure over a dynamic stream. Notice that [BFL16] gave a sensitivity sampling framework that works for clustering with general loss functions, and our method can be extended to those problems as well.

27.3 An Offline Sensitivity Sampling Procedure

In this section, we consider the *offline* setting in which all the data points are given. In this setting, we design a coreset construction algorithm based on sensitivity sampling. In Section 27.6, we will show how to implement this algorithm in the dynamic streaming setting.

27.3.1 Randomly Shifted Grids

We consider data points from $[\Delta]^d$ and assume without loss of generality that $\Delta = 2^L$ for some positive integer L. The space $[\Delta]^d$ is partitioned by a hierarchical grid structure as follows. The first level (level 0) of the grid contains *cells* with side-length Δ such that all the data points are contained in a single cell. For each higher level, we refine the grid by splitting each cell into 2^d equal sized sub-cells. In the finest level, i.e., the L-th level, each cell contains a single point. We further randomly shift the boundary of the grids to achieve certain properties, which we will show later. Formally, our grid structure is defined as the following.

Definition 27.3.1 (Grids and cells)**.** Let $g_0 = \Delta$. Choose a vector v uniformly at random from $[0, \Delta]^d$. Partition the space $\mathbb{R}^d$ into a regular Cartesian grid G_0 with side-length g_0 and translate G_0 such that a vertex of this grid falls on v. The grid G_0 can be regarded as an infinite set of disjoint *cells*, where each cell $C \in G_0$ can be expressed as

$$[v_1 + n_1 g_0,\ v_1 + (n_1 + 1)g_0) \times \cdots \times [v_d + n_d g_0,\ v_d + (n_d + 1)g_0) \subset \mathbb{R}^d$$

for some $(n_1, n_2, \ldots, n_d) \in \mathbb{Z}^d$. (Note that each cell is a Cartesian product of intervals.)

For $i \geq 1$, we define the regular grid G_i as the grid with side-length $g_i = g_0/2^i$ aligned such that each cell in G_{i-1} contains 2^d cells in G_i. The finest grid is G_L where $L = \log_2 \Delta$. A cell of G_L has side-length 1 and thus contains at most one data point.

For convenience, we also define G_{-1} to be the regular grid with side-length $g_{-1} = 2\Delta$, and each cell in G_{-1} is a union of 2^d cells in G_0. Since the data points are in $[\Delta]^d$, there must be a single cell in G_{-1} which contains all the data points. Consider two cells $C \in G_i$ and $C' \in G_j$ for some $i, j \in \{-1, 0, 1, \ldots, L\}$. If $C' \subset C$, then C is an *ancestor* of C'. Furthermore, if $i = j - 1$, then C is the *parent* of C' and C' is a *child* of C. Thus every cell which is not from G_L has exactly 2^d children cells. For a point p (or a set P of points), $c_i(p)$ (or $c_i(P)$) denotes the cell C in grid G_i which contains p (or P). If i is clear from the context, we will just use $c(p)$ (or $c(P)$) for short.

27.3.2 Sensitivity Estimation and Coreset Construction

In Algorithm 27.1 we describe how to assign a sensitivity upper bound for every point. It needs an estimate o of the optimal k-means cost OPT. We will show how to enumerate the guesses o later. According to Theorem 27.2.1, it directly gives an offline coreset construction algorithm.

We also give an alternative sampling procedure in Algorithm 27.2 which is useful for the dynamic streaming model.

Theorem 27.3.1. *Suppose that for any $i \in \{0, 1, \ldots, L\}$ and for any cell $C \in G_i$ with $C \cap Q \neq \emptyset$, the estimated value z in line 27.1 of Algorithm 27.1 satisfies either $z \in |C \cap Q| \pm 0.1T_i(o)$ or $z \in (1 \pm 0.01) \cdot |C \cap Q|$, and for any Q_i, the estimated value $\widehat{q_i}$ in line 27.2*

Algorithm 27.1 Sensitivity Estimation

predetermined: a guess $o \in [1, \Delta^d \cdot d\Delta]$ of the optimal k-means cost OPT
input: a point set $Q \subseteq [\Delta]^d$, a parameter $k \in \mathbb{N}_+$
Impose randomly shifted grids $G_{-1}, G_0, G_1, \ldots, G_L$ (Definition 27.3.1).
Let $C \in G_{-1}$ be the cell which contains Q, i.e., $C = c(Q)$. Mark C as *heavy*.
for $i := 0 \to L - 1$ **do**
    Set the threshold value $T_i(o) = (d/g_i)^2 \cdot o/k \cdot 1/100$.
    for $C \in G_i$ with $C \cap Q \neq \emptyset$ **do**
        Let z be an estimated value of $|C \cap Q|$ up to some precision.
        If $z \geq T_i(o)$, mark C as heavy.
        Otherwise, if all the ancestors of C are marked as heavy, mark C as *crucial*.
    end for
end for
For $C \in G_L$, if all the ancestors of C are marked as heavy, mark C as crucial.
Initialize $Q_0 = Q_1 = \cdots = Q_L = \emptyset$.
For $p \in Q$, if $c_i(p)$ is marked as crucial, add p into set Q_i and set $s'(p) = 10d^3/T_i(o)$.
output: $Q_0, Q_1, \ldots, Q_L$ and $s'(\cdot)$

of Algorithm 27.2 satisfies either $\widehat{q_i} \in |Q_i| \pm 0.1\epsilon\gamma T_i(o)$ *or* $\widehat{q_i} \in (1 \pm 0.01\epsilon) \cdot |Q_i|$. *Suppose* $o \in (0, \mathrm{OPT}]$. *Then the set* S *output by Algorithm 27.2 is an* ϵ*-coreset (Definition 27.2.3) for* Q. *Furthermore, with probability at least* 0.93, $|S|$ *is at most*

$$O(k\epsilon^{-2}d^4L^2 \log(kdL) \cdot (\mathrm{OPT}/o + 1)).$$

27.3.3 Analysis

Now we give the proof of Theorem 27.3.1. All the missing proofs in this section are given in Section 27.5. Let us first state some simple facts.

Fact 27.3.2. *The point sets* $Q_0, Q_1, \ldots, Q_L$ *obtained by Algorithm 27.1 form a partition of* Q, *i.e., for all* $p \in Q$, *there is exactly one* $i \in \{0, 1, \ldots, L\}$ *such that* $p \in Q_i$.

Algorithm 27.2 Sensitivity Sampling Based Coreset Construction

predetermined: a guess o of the optimal k-means cost OPT, an error parameter $\epsilon \in (0, 0.5)$
input: a point set $Q \subset [\Delta]^d$, a parameter $k \in \mathbb{N}_+$
Let $Q_0, Q_1, \ldots, Q_L$ and $s'(\cdot)$ be the output of Algorithm 27.1.
Let $\widehat{q}_0, \widehat{q}_1, \ldots, \widehat{q}_L$ be the estimated values of $|Q_0|, |Q_1|, \ldots, |Q_L|$ respectively.
For $i \in \{0, 1, \ldots, L\}$, set $T_i(o) = (d/g_i)^2 \cdot o/k \cdot 1/100$ (same as in Algorithm 27.1).
Set $\gamma = \epsilon/(40^2 L d^3)$.
Let $I = \{i \mid 0 \le i \le L, \widehat{q}_i \ge \gamma T_i(o)\}$.
Let $Q^I = \bigcup_{i \in I} Q_i$. ▷ Only consider the levels with sufficient number of points.
Set $t' = \sum_{i \in I} \widehat{q}_i \cdot 10d^3/T_i(o)$. ▷ Total estimated sensitivities.
Set $m = \Theta(t' \epsilon^{-2} L d \log t')$ and initialize $S = \emptyset$. ▷ m is the total number of samples.
for $j = 1 \to m$ **do**
    Choose a random level $i \in I$ with probability $(\widehat{q}_i \cdot 10d^3/T_i(o))/t'$.
    Uniformly sample a point p from Q_i.
    Add $(p, t'/(ms'(p)))$ to set S.
end for
output: the set S

Fact 27.3.3. *For $C \in G_i$, if C is marked as heavy, then $|C \cap Q| \ge 0.9T_i(o)$; otherwise $|C \cap Q| \le 1.1T_i(o)$. Similarly, if $i \in I$, then $|Q_i| \ge 0.9\gamma T_i(o)$; otherwise $|Q_i| \le 1.1\gamma T_i(o)$.*

Fact 27.3.4. *For Q_i output by Algorithm 27.1, every point $p \in Q_i$ is assigned the same sensitivity upper bound $s'(p) = 10d^3/T_i(o)$.*

In line 27.2 of Algorithm 27.2, we set I to be the set of levels such that there are sufficient number of points in the crucial cells in those levels. The following lemma shows that the point set Q^I (line 27.2 of Algorithm 27.2) is a good representative of the point set Q, i.e., for any set of k centers Z, the k-means cost $\mathrm{cost}(Q, Z)$ is close to the $\mathrm{cost}(Q^I, Z)$.

Lemma 27.3.5. *Let Q^I and ϵ be the same as in Algorithm 27.2. If $o \in (0, \mathrm{OPT}]$, then for*

any $Z \subseteq \mathbb{R}^d$ with $|Z| = k$, we have:

$$\operatorname{cost}(Q^I, Z) \leq \operatorname{cost}(Q, Z) \leq (1 + \epsilon/10) \operatorname{cost}(Q^I, Z).$$

Next, instead of showing $s'(p)$ (output by Algorithm 27.1) is a sensitivity upper bound with respect ot Q, we show that $s'(p)$ is also an sensitivity upper bound with respect to Q^I. This is even stronger since Q^I is a subset of Q and we have:

$$\forall Z \subseteq \mathbb{R}^d : |Z| = k, \ \frac{\operatorname{dist}^2(p, Z)}{\sum_{q \in Q} \operatorname{dist}^2(q, Z)} \leq \frac{\operatorname{dist}^2(p, Z)}{\sum_{q \in Q^I} \operatorname{dist}^2(q, Z)}.$$

Lemma 27.3.6. *Let Q^I be the same as in Algorithm 27.2. If $o \in (0, \mathrm{OPT}]$, then for all $i \in \{0, 1, 2, \ldots, L\}$ and $p \in Q_i$, we have:*

$$\max_{Z \subseteq \mathbb{R}^d : |Z| = k} \frac{\operatorname{dist}^2(p, Z)}{\sum_{q \in Q^I} \operatorname{dist}^2(q, Z)} \leq 10 \frac{d^3}{T_i(o)} = s'(p).$$

Now, we explain the reason of imposing randomly shifted grids. We fix an optimal set $Z^* = \{z_1^*, z_2^*, \ldots, z_k^*\} \subset \mathbb{R}^d$ of k centers for the point set Q, i.e., $\operatorname{cost}(Q, Z^*) = \mathrm{OPT}$. We call a cell $C \in G_i$ a *center cell* if it is close to a center in Z^*, namely $\operatorname{dist}(C, Z^*) \leq g_i/(2d)$. We claim that there will not be too many center cells since we randomly shift the grids. In other words, each center of Z^* is far from the boundary of every gird.

Lemma 27.3.7. *With probability at least 0.94, the total number of center cells is at most $100kL$.*

This lemma is similar to Lemma 2.2 in [BFL+17]. For completeness, we also provide a proof in Section 27.5.

Consider the total estimated sensitivities, i.e., the sum of the sensitivity upper bounds over all the points. Due to Theorem 27.2.1, this sum determines the size of the coreset. We show that if the estimate o of the optimal k-means cost is close to OPT, then the total estimated sensitivities can not be too large.

Lemma 27.3.8. *Suppose the number of center cells is at most* $100kL$. *Let* $Q_0, Q_1, \ldots, Q_L, s'(\cdot)$ *be the output of Algorithm 27.1. Then the total estimated sensitivities satisfies*

$$\sum_{p\in Q} s'(p) \le 4000kLd^3 \cdot (\mathrm{OPT}/o + 1).$$

Since Q^I is a subset of Q, according to the above lemma, we also have $\sum_{p\in Q^I} s'(p) \le 4000d^3Lk \cdot (\mathrm{OPT}/o + 1)$. Now, we are ready to prove Theorem 27.3.1.

Proof of Theorem 27.3.1. By Lemma 27.3.7, with probability at least 0.94, the number of center cells is at most $100kL$. In the following, we condition on this event.

Algorithm 27.2 draws m i.i.d. samples. For each sample, a point $p \in Q_i \subseteq Q^I$ is chosen with probability

$$\frac{\widehat{q}_i/T_i(o)}{\sum_{j\in I}\widehat{q}_j/T_j(o)} \cdot \frac{1}{|Q_i|} = \frac{\frac{\widehat{q}_i}{|Q_i|}\cdot 20\frac{d^3}{T_i(o)}}{\sum_{j\in I}\sum_{p'\in Q_j}\frac{\widehat{q}_j}{|Q_j|}\cdot 20\frac{d^3}{T_j(o)}}.$$

Each sample p is given a weight

$$\frac{t'}{ms'(p)} = \frac{1}{m}\cdot\frac{\sum_{j\in I}\sum_{p'\in Q_j}\frac{\widehat{q}_j}{|Q_j|}\cdot 20\frac{d^3}{T_j(o)}}{\frac{\widehat{q}_i}{|Q_i|}\cdot 20\frac{d^3}{T_i(o)}}\cdot\frac{\widehat{q}_i}{|Q_i|} \in (1\pm\epsilon/4)\cdot\frac{1}{m}\cdot\frac{\sum_{j\in I}\sum_{p'\in Q_j}\frac{\widehat{q}_j}{|Q_j|}\cdot 20\frac{d^3}{T_j(o)}}{\frac{\widehat{q}_i}{|Q_i|}\cdot 20\frac{d^3}{T_i(o)}}.$$

Let $s''(p) = \frac{\widehat{q}_i}{|Q_i|} \cdot 20\frac{d^3}{T_i(o)}$. Since $\widehat{q}_i/|Q_i| \geq 1/2$, we know that $s''(p)$ is still a sensitivity upper bound of p with respect to Q^I by Lemma 27.3.6. According to Algorithm 27.2, we have $t' = \frac{1}{2}\sum_{p\in Q^I} s''(p)$. Therefore, if we set m to be a sufficiently large $\Omega(t'\epsilon^{-2}Ld\log t') = \Omega(t'\epsilon^{-2}(\log(\Delta^d)\log t' + \log(1/0.01)))$, then according to Theorem 27.2.1, S output by Algorithm 27.2 is an $\epsilon/2$-coreset for Q^I with probability at least 0.99. By Lemma 27.3.5, if S is an $\epsilon/2$-coreset for Q^I, then S is also an ϵ-coreset for Q. Thus, the correctness is proved, and the overall success probability is at least 0.93 obtained by a simple union bound. Now let us analyze the size of the coreset S. Since $\forall j \in I, \widehat{q}_j/|Q_j| \leq 2$, we have $\sum_{j\in I}\sum_{p'\in Q_j} s''(p') \leq 2t' \leq 4 \cdot 4000d^3Lk \cdot (\mathrm{OPT}/o + 1)$ by Lemma 27.3.8. Thus, the size of S is $m = O(k\epsilon^{-2}d^4L^2\log(kdL) \cdot (\mathrm{OPT}/o + 1))$. □

27.4 Conclusion

This paper gives the first k-means coreset construction in the dynamic streaming model using space polynomial in the dimension d and nearly optimal (linear) in k. The algorithm is based on sensitivity sampling, which we believe is a powerful tool and can have broader applications.

27.5 Missing Details in Section 27.3

Proof of Fact 27.3.2. Consider an arbitrary point $p \in Q$. Let $C_{-1}, C_0, \ldots, C_L$ be the cells which contain p, where $\forall i \in \{-1, 0, 1, \ldots, L\}$, the cell C_i is from the grid G_i. According to Algorithm 27.1, C_{-1} is marked as heavy and C_L cannot be marked as heavy. Let l be the largest integer such that all the cells $C_{-1}, C_0, \ldots, C_{l-1}$ are marked as heavy. Then the cell C_l must be marked as crucial, and all the cells $C_{l+1}, C_{l+2}, \ldots, C_L$ can not be crucial. Thus, we have $p \in Q_l$ and $\forall i \in \{0, 1, \ldots, L\} \setminus \{l\}$, $p \notin Q_i$. □

Facts 27.3.3 and 27.3.4 are obvious from the algorithms, so we omit the proofs.

The following claim is useful in the proofs.

Claim 27.5.1. *Let Q^I and γ be the same as mentioned in Algorithm 27.2. For $i \in \{0, 1, \ldots, L\}$ and any heavy cell $C \in G_{i-1}$, if all the ancestors of C are marked as heavy, then we have $|C \cap Q^I| \geq (1 - 5(L - i)\gamma) \cdot |C \cap Q|$.*

Proof. The proof is by induction. When $i = L$, consider a heavy cell $C \in G_{L-1}$ whose ancestors are also heavy. If there is no such cell C, then the claim holds directly for $i = L$. Otherwise, according to the construction of $Q_0, Q_1, \ldots, Q_L$, $\forall j \in \{0, 1, \ldots, L-1\}$, we have $Q_j \cap C = \emptyset$ and $(Q \cap C) \subseteq Q_L$. Since C is marked as heavy, we know that $|Q_L \cap C| = |Q \cap C| \geq 0.9T_{L-1}(o) \geq 0.9T_L(o)/4$. It implies that $\widehat{q}_L \geq \min(|Q_L| - 0.1\epsilon\gamma T_L(o), (1 - 0.01\epsilon)|Q_L|) \geq \min(|Q \cap C| - 0.1\epsilon\gamma T_L(o), (1 - 0.01\epsilon)|Q \cap C|) \geq \gamma T_L(o)$. Thus, we have $Q_L \subseteq Q^I$ which implies that $|C \cap Q^I| = |C \cap Q_L| = |C \cap Q|$.

Now assume the claim is true for $i + 1, i + 2, \ldots, L$. Consider a heavy cell $C \in G_{i-1}$ whose ancestors are also marked as heavy. If there is no such cell C, the claim holds directly

for i. Now consider the case when C exists. If level $i \in I$, i.e., $Q_i \subseteq Q^I$, we have

$$\begin{aligned}
|C \cap Q^I| &= \sum_{C' \in G_i : C' \text{ is a heavy child of } C} |C' \cap Q^I| + \sum_{C' \in G_i : C' \text{ is a crucial child of } C} |C' \cap Q^I| \\
&= \sum_{C' \in G_i : C' \text{ is a heavy child of } C} |C' \cap Q^I| + |C \cap Q_i| \\
&\geq (1 - 5(L - i - 1)\gamma) \sum_{C' \in G_i : C' \text{ is a heavy child of } C} |C' \cap Q| + |C \cap Q_i| \\
&\geq (1 - 5(L - i - 1)\gamma)|C \cap Q| \\
&\geq (1 - 5(L - i)\gamma)|C \cap Q|.
\end{aligned}$$

If level $i \notin I$, i.e., $Q_i \not\subseteq Q^I$, we have

$$\begin{aligned}
\sum_{C' \in G_i : C' \text{ is a heavy child of } C} |C' \cap Q| &\geq |C \cap Q| - |Q_i| \\
&\geq |C \cap Q| - 1.1\gamma T_i(o) \\
&\geq (1 - 5\gamma)|C \cap Q|.
\end{aligned}$$

Thus,

$$\begin{aligned}
|C \cap Q^I| &\geq \sum_{C' \in G_i : C' \text{ is a heavy child of } C} |C' \cap Q^I| \\
&\geq (1 - 5(L - i - 1)\gamma) \cdot \sum_{C' \in G_i : C' \text{ is a heavy child of } C} |C' \cap Q| \\
&\geq (1 - 5(L - i - 1)\gamma)(1 - 5\gamma)|C \cap Q| \\
&\geq (1 - 5(L - i)\gamma)|C \cap Q|.
\end{aligned}$$

□

Proof of Lemma 27.3.5. Since Q^I is a subset of Q, $\text{cost}(Q^I, Z) \leq \text{cost}(Q, Z)$ is trivial. In the following, we are trying to prove $\text{cost}(Q, Z) \leq (1 + \epsilon/10)\,\text{cost}(Q^I, Z)$.

We consider an level $i \notin I$, i.e., $Q_i \not\subseteq Q^I$. For a point $p \in Q_i$, all the ancestors of $c_i(p)$ must be heavy. By averaging argument, there must exist a point $q \in c_{i-1}(p) \cap Q^I$ such that

$$\begin{aligned}
\operatorname{dist}^2(p, Z) &\leq 2\operatorname{dist}^2(p, q) + 2\operatorname{dist}^2(q, Z) \\
&\leq 2dg_{i-1}^2 + 2\operatorname{dist}^2(q, Z) \\
&\leq 2dg_{i-1}^2 + 2\frac{1}{|c_{i-1}(p) \cap Q^I|} \sum_{q \in c_{i-1}(p) \cap Q^I} \operatorname{dist}^2(q, Z) \qquad (27.1)
\end{aligned}$$

where the first step follows from triangle inequality, the second step follows from definition of the grids, the last step follows from an averaging argument.

According to Claim 27.5.1, we have

$$|c_{i-1}(p) \cap Q^I| \geq \frac{1}{2} T_{i-1}(o).$$

Let $Q^N = Q \setminus Q^I$. We can lower bound $\text{cost}(Q, Z)$ in the following sense,

$$\begin{aligned}
\text{cost}(Q, Z) &= \text{cost}(Q^I, Z) + \text{cost}(Q^N, Z) \\
&= \text{cost}(Q^I, Z) + \sum_{i \notin I} \sum_{p \in Q_i} \text{dist}^2(p, z) \\
&\leq \text{cost}(Q^I, Z) + 2 \sum_{i \notin I} \sum_{p \in Q_i} \left(dg_{i-1}^2 + \frac{1}{|c_{i-1}(p) \cap Q^I|} \sum_{q \in c_{i-1}(p) \cap Q^I} \text{dist}^2(q, Z) \right) \\
&\leq \text{cost}(Q^I, Z) + 2 \sum_{i \notin I} \sum_{p \in Q_i} \left(dg_{i-1}^2 + \frac{2}{T_{i-1}(o)} \sum_{q \in c_{i-1}(p) \cap Q^I} \text{dist}^2(q, Z) \right) \\
&\leq \text{cost}(Q^I, Z) + 2 \sum_{i \notin I} \sum_{p \in Q_i} \left(dg_{i-1}^2 + \frac{2}{T_{i-1}(o)} \sum_{q \in Q^I} \text{dist}^2(q, Z) \right) \\
&\leq \text{cost}(Q^I, Z) + 2 \sum_{i \notin I} 1.1 \gamma T_i(o) \cdot \left(dg_{i-1}^2 + \frac{2}{T_{i-1}(o)} \sum_{q \in Q^I} \text{dist}^2(q, Z) \right) \\
&\leq \text{cost}(Q^I, Z) + 5L\gamma T_i(o) \cdot \left(dg_{i-1}^2 + \frac{2}{T_{i-1}(o)} \sum_{q \in Q^I} \text{dist}^2(q, Z) \right) \\
&= \text{cost}(Q^I, Z) + 5L\gamma T_i(o) \cdot \left(dg_{i-1}^2 + \frac{2}{T_{i-1}(o)} \text{cost}(Q^I, Z) \right) \\
&\leq \text{cost}(Q^I, Z) + 5L\gamma (d^3 o/(25k) + 8 \, \text{cost}(Q^I, Z)) \\
&\leq \text{cost}(Q^I, Z) + 5L\gamma (d^3 \, \text{cost}(Q, Z)/(25k) + 8 \, \text{cost}(Q^I, Z)).
\end{aligned}$$

where the second step follows from the definition of the cost, the third step follows from Eq. (27.1), the fourth step follows from $|c_{i-1}(p) \cap Q^I| \geq T_{i-1}(o)/2$, the fifth step follows from $(c_{i-1}(p) \cap Q^I) \subset Q^I$, the sixth step follows from $|Q_i| \leq 1.1\gamma T_i(o)$, the seventh step follows from $L + 1 - |I| \leq L + 1 \leq 2L$ and $2 \cdot 2 \cdot 1.1 \leq 5$, the ninth step follows from $T_i(o) = 4T_{i-1}(o)$ and $T_i(o) = (d/g_i)^2 \cdot o/k \cdot 1/100$, and the last step follows from $o \leq \text{OPT} \leq \text{cost}(Q, Z)$.

It implies that

$$\begin{aligned}\frac{\text{cost}(Q,Z)}{\text{cost}(Q^I,Z)} &\leq \frac{1+40L\gamma}{1-5L\gamma d^3/(25k)}\\ &\leq \frac{1+\epsilon/40}{1-\epsilon/40}\\ &\leq 1+\epsilon/10,\end{aligned}$$

where the second step follows from $\gamma \leq \epsilon/(40^2 L d^3)$, and the last step follows from $\epsilon < 1$. □

Proof of Lemma 27.3.6. Let $Z \subseteq \mathbb{R}^d$ be an arbitrary set of k centers. Fix a point $p \in Q$. Suppose p is in Q_i, i.e., p is in a crucial cell of G_i. Let $C = c_{i-1}(p)$, i.e., C is the parent cell of the crucial cell that contains p. By Algorithm 27.1, C and all of its ancestors must be heavy. By Claim 27.5.1, $C \cap Q^I$ cannot be empty. Thus, by an averaging argument, there is a point $p' \in C$ such that

$$\text{dist}^2(p', Z) \leq \frac{1}{|C \cap Q^I|} \sum_{q \in C \cap Q^I} \text{dist}^2(q, Z). \tag{27.2}$$

We have

$$\begin{aligned}
\frac{\operatorname{dist}^2(p,Z)}{\sum_{q\in Q^I}\operatorname{dist}^2(q,Z)} &\le 2\frac{\operatorname{dist}^2(p',Z)}{\sum_{q\in Q^I}\operatorname{dist}^2(q,Z)} + 2\frac{\operatorname{dist}^2(p,p')}{\sum_{q\in Q^I}\operatorname{dist}^2(q,Z)} \\
&\le 2\frac{\sum_{q\in C\cap Q^I}\operatorname{dist}^2(q,Z)}{|C\cap Q^I|\sum_{q\in Q^I}\operatorname{dist}^2(q,Z)} + 2\frac{dg_{i-1}^2}{\sum_{q\in Q^I}\operatorname{dist}^2(q,Z)} \\
&\le 2\frac{\sum_{q\in Q^I}\operatorname{dist}^2(q,Z)}{|C\cap Q^I|\sum_{q\in Q^I}\operatorname{dist}^2(q,Z)} + 2\frac{dg_{i-1}^2}{\sum_{q\in Q^I}\operatorname{dist}^2(q,Z)} \\
&= 2\frac{1}{|C\cap Q^I|} + 2\frac{dg_{i-1}^2}{\sum_{q\in Q^I}\operatorname{dist}^2(q,Z)} \\
&\le 2\frac{1}{|C\cap Q^I|} + 4\frac{dg_{i-1}^2}{\mathrm{OPT}} \\
&\le 2\frac{1}{|C\cap Q^I|} + 16\frac{dg_i^2}{\mathrm{OPT}} \\
&\le 2\frac{1}{|C\cap Q^I|} + \frac{d^3o}{T_i(o)k\,\mathrm{OPT}} \\
&\le 9\frac{1}{T_i(o)} + \frac{d^3o}{T_i(o)k\,\mathrm{OPT}} \\
&\le 9\frac{1}{T_i(o)} + \frac{d^3}{T_i(o)} \\
&\le 10\frac{d^3}{T_i(o)}
\end{aligned}$$

where the first step follows from triangle inequality, the second step follows from Eq. (27.2) and $p' \in c_{i-1}(p)$, the fifth step follows from $\sum_{q\in Q^I}\operatorname{dist}^2(q,Z) \ge (1-\epsilon)\operatorname{cost}(Q,Z) \ge \mathrm{OPT}/2$ (Lemma 27.3.5), the sixth step follows from $g_{i-1}^2 \le 4g_i^2$, the seventh step follows from $T_i(o) = \frac{d^2}{g_i^2}\frac{o}{100k}$, the eighth step follows from $T_i(o) = 4T_{i-1}(o) \le 4.5|C\cap Q^I|$ (Claim 27.5.1 and $|C\cap Q| \ge 0.9T_{i-1}(o)$), the ninth step follows from $1/k \le 1, o \le \mathrm{OPT}$. □

Proof of Lemma 27.3.7. Fix an $i \in \{0,1,\ldots,L\}$ and consider the grid G_i. For each optimal center z_j^*, we use $X_{j,\alpha}$ to denote the indicator random variable for the event that the distance

from z_j^* to the boundary in dimension α of the grid G_i is at most $g_i/(2d)$. Since in each dimension, if the center is close to a boundary, it contributes a factor at most 2 to the total number of center cells. It follows that the number of cells that have distance at most $g_i/(2d)$ to z_j^* is at most

$$N = 2^{\sum_{\alpha=1}^{d} X_{j,\alpha}}.$$

We denote $Y_{j,\alpha}$ to be $2^{X_{j,\alpha}}$, then

$$\mathbb{E}[N] = \mathbb{E}\left[\prod_{\alpha=1}^{d} Y_{j,\alpha}\right] = \prod_{\alpha=1}^{d} \mathbb{E}[Y_{j,\alpha}].$$

By using $\Pr[X_{j,\alpha} = 1] \leq (2g_i/(2d))/g_i = 1/d$, we obtain

$$\mathbb{E}[Y_{j,\alpha}] \leq \mathbb{E}[1 + X_{j,\alpha}] = 1 + \mathbb{E}[X_{j,\alpha}] \leq 1 + 1/d.$$

Thus $\mathbb{E}[N] = \prod_{\alpha=1}^{d} \mathbb{E}[Y_{j,\alpha}] \leq (1 + 1/d)^d \leq e$. The expected number of center cells in a single grid is at most $(1 + 1/d)^d k \leq ek \leq 3k$. By linearity of expectation, the expected number of center cells in all grids is at most $ek(L + 1) \leq 6kL$. By Markov's inequality, the probability that we have more than $100kL$ center cells in all grids is at most 0.06. □

Proof of Lemma 27.3.8. We have

$$\begin{aligned}
\sum_{p\in Q} s'(p) &= \sum_{i=0}^{L} \sum_{p\in Q_i} 10\frac{d^3}{T_i(o)} \\
&= 10d^3 \sum_{i=0}^{L} \frac{1}{T_i(o)} \left(\sum_{\text{center cell } C\in G_i} |C\cap Q_i| + \sum_{\text{non-center cell } C\in G_i} |C\cap Q_i| \right) \\
&\le 10d^3 \sum_{i=0}^{L} \frac{1}{T_i(o)} \left(\sum_{\text{center cell } C\in G_i} 1.1T_i(o) + \frac{\mathrm{OPT}}{g_i^2/(2d)^2} \right) \\
&\le 11d^3 \cdot (\#\text{ of center cells}) + 4000d^3Lk \cdot \frac{\mathrm{OPT}}{o} \\
&\le 1100d^3Lk + 4000d^3Lk \cdot \frac{\mathrm{OPT}}{o} \\
&\le 4000d^3Lk \cdot \left(\frac{\mathrm{OPT}}{o} + 1 \right),
\end{aligned}$$

where the first step follows from the definition of $s'(p)$, the third step follows from

1. if $C \in G_i$ and $C \cap Q_i \neq \emptyset$, then $|C \cap Q_i| = |C \cap Q| \le 1.1T_i(o)$;
2. if p is in a non-center cell $C \in G_i$, then $\mathrm{dist}^2(p, Z^*) \ge g_i^2/(2d)^2$,

the forth step follows from $g_i^2/d^2 = o/(100kT_i(o))$, the fifth step follows from that the total number of center cells is bounded by $100kL$. □

27.6 Coreset Construction over a Dynamic Stream

In this section, we show how to implement Algorithms 27.1 and 27.2 in the dynamic streaming setting.

First, we introduce a dynamic storage structure that allows us to insert and delete points or cells. We then use this data structure combined with hash functions to estimate the number of points falling into each cell. Lastly, we combine them with the sensitivity sampling procedure to obtain our final algorithm.

Algorithm 27.3 Point-cell storing procedure

1: STORING$(G_i, \alpha, \beta, \delta)$:
2: **Input:** $\{((p_1, l_1), \pm), ((p_2, l_2), \pm), \ldots\}$ ▷ $l_t \in [\widehat{m}]$. Only Algorithm 27.5 uses the case for $\widehat{m} > 1$.
3: Run DISTINCT$(\alpha, \delta/4)$ on $\{(c_i(p_1), \pm), (c_i(p_2), \pm), \ldots\}$ in parallel.
4: Set $r = \lceil \log(4\alpha/\delta) \rceil$ and $h_1, h_2, \ldots, h_r$, $\forall j \in [r]$, $h_j : G_i \to [2\alpha]$. ▷ h_j is pairwise independent.
5: Run $r \cdot 2\alpha$ copies of DISTINCT$(\beta, \delta/(2\alpha))$ in parallel.
6: ▷ Each copy is indexed by a pair $(j, b) \in [r] \times [2\alpha]$. The (j, b)-th copy is run on the sub-stream $\{((p'_1, l'_1), \pm), ((p'_2, l'_2), \pm), \ldots\}$, where each $((p'_t, l'_t), \pm)$ satisfies $h_j(c_i(p'_t)) = b$.
7: If line 27.3 returns **FAIL**, output **FAIL**; otherwise, let $\mathcal{C}, f : \mathcal{C} \to \mathbb{N}_+$ be the output of line 27.3.
8: ▷ $\mathcal{C} \subset G_i$ contains all the cells found, and $f(C)$ denotes the number of points in C.
9: Initialize $S \leftarrow \emptyset$.
10: **for** $C \in \mathcal{C}$ with $f(C) \le \beta$ **do**
11: Find $j \in [r]$ s.t. $\forall C' \in \mathcal{C}, h_j(C) \neq h_j(C')$ and the $(j, h_j(C))$-th copy in line 27.3 does not **FAIL**.
12: If such j does not exist, output **FAIL**; otherwise $S \leftarrow S \cup S_{j,h_j(C)}$.
13: ▷ Here $S_{j,h_j(C)}$ is the set of distinct points found by the $(j, h_j(C))$-th copy in line 27.3.
14: **end for**
15: **Output:** $\mathcal{C} \subset G_i, f : \mathcal{C} \to \mathbb{N}_+, S = \{(\widetilde{p}_1, \widetilde{l}_1), (\widetilde{p}_2, \widetilde{l}_2), \ldots\}$

27.6.1 The Dynamic Point-Cell Storing Data Structure

We introduce an algorithm that maintains a set of points and cells in a dynamic data stream. Before that, let us recall [Gan05]'s result for finding distinct elements, which we use as a subroutine in our algorithm.

Lemma 27.6.1 (Distinct elements [Gan05])**.** *Given parameters $M \geq 1, N \geq 1, s \geq 1, \delta \in (0, 1/2)$, there is an algorithm* DISTINCT(s, δ) *that requires $O(s(\log M + \log N)\log(s/\delta))$ bits to process a stream of insertion/deletion of data items. For each operation $(i, \pm)$ ($i \in [N]$), the algorithm takes $O(\log(s/\delta))$ time. M is an upper bound of the total frequency of all items during the stream. At the end of the stream, if the number of distinct elements is at most s, with probability at least $1 - \delta$ it returns all the distinct elements and their frequencies. It returns* ***FAIL*** *otherwise.*

We use DISTINCT as our sub-routine. We set the parameter M and N to be sufficiently large in our case, i.e., $M = N = \Delta^{2d}$. In Algorithm 27.3, we describe a method which can with probability at least $1-\delta$ output all the non-empty cells in grid G_i when the total number of non-empty cells is not too large (at most α). Furthermore, if the number of points in a particular cell is not too large (at most β), the algorithm can output all the points in that cell. Notice that Algorithm 27.3 is only a subroutine of our final algorithm and will only work on some sub-stream of the entire data stream.

The following lemma shows the guarantee of Algorithm 27.3.

Lemma 27.6.2. *Given parameters $i \in [L], \alpha, \beta \in \mathbb{N}_+, \delta \in (0, 0.5)$,* STORING$(G_i, \alpha, \beta, \delta)$ *(Algorithm 27.3) uses $O(\alpha\beta dL \cdot \log^2(\alpha\beta/\delta))$ bits to process a stream $\{((p_1, l_1), \pm), ((p_2, l_2), \pm), \ldots\}$ of insertion/deletion operations of data points. At the end of the stream, if the number of*

*non-empty cells in G_i is at most α, then with probability at least $1-\delta$ it returns the set $\mathcal{C}$ of all the non-empty cells, the number of points $f(C)$ in each cell $C \in \mathcal{C}$, and the set S of points in all the non-empty cells that contain at most β points. It returns **FAIL** otherwise.*

Proof. If the number of non-empty cells of G_i at the end of the stream is more than α, then according to line 27.3 of Algorithm 27.3 and Lemma 27.6.1, Algorithm 27.3 must output **FAIL**.

Now consider the case when the total number of non-empty cells is at most α. According to Lemma 27.6.1, with probability at least $1-\delta/4$, line 27.3 of Algorithm 27.3 will return the set $\mathcal{C}$ of all the non-empty cells of G_i and the number of points $f(C)$ for each cell $C \in \mathcal{C}$. For each $C \in \mathcal{C}$ with $|C| \leq \beta$, since $|\mathcal{C}| \leq \alpha$, the probability that $\exists j \in [r]$ such that $\forall C' \in \mathcal{C}, h_j(C') \neq h_j(C)$ is at least $1 - 1/2^r \geq 1 - \delta/(4\alpha)$ and furthermore the probability that the $(j, h_j(C))$-th copy of $\textsc{Distinct}(\beta, \delta/(2\alpha))$ in line 27.3 of Algorithm 27.3 will output all the points in C is at least $1-\delta/(2\alpha)$. By taking union bound, the overall probability that Algorithm 27.3 does not output **FAIL** is at most $1 - \delta/4 - (\delta/(2\alpha) + \delta/(4\alpha)) \cdot \alpha = 1 - \delta$.

According to Lemma 27.6.1, the space needed by line 27.3 of Algorithm 27.3 is $O(\alpha dL \cdot \log(\alpha/\delta))$ bits and the space needed of each copy in line 27.3 of Algorithm 27.3 is $O(\beta dL \cdot \log(\alpha\beta/\delta))$ bits. Thus, the total space needed is at most $O(\alpha\beta dL \cdot \log^2(\alpha\beta/\delta))$. □

27.6.2 Estimating the Number of Points in Each Cell

We use Algorithm 27.3 as a subroutine and design a dynamic streaming algorithm (Algorithm 27.4) that can estimate the number of points in each cell up to some precision. Furthermore, it also estimates the number of points $|Q_i|$ in crucial cells of each level i.

Algorithm 27.4 Estimating the number of points in each cell and in each level

PointsEstimation(o, ϵ, δ):
Input: a point set $Q \subseteq [\Delta]^d$ described by a stream $\{(p_1, \pm), (p_2, \pm), \ldots\}$
for $i \in \{0, 1, \ldots, L\}$, in parallel, **do**
  $T_i(o) \leftarrow (d/g_i)^2 \cdot o/(100k)$, $\alpha \leftarrow 10^{11} kLd \log(1/\delta)$, $\alpha' \leftarrow 10^{16}\epsilon^{-3}kL^2d^4$.
  ▷ $T_i(o)$: threshold for heaviness (Algortihm 27.1); α, α': parameters for Storing.
  Let $h_i : [\Delta]^d \to \{0, 1\}$ be a λ-wise independent hash function.
    ▷ $\lambda = 10\lceil (dL + \log(1/\delta) + 1)\rceil$; $\forall p \in [\Delta]^d, h_i(p) = 1$ w.p. $\min(4 \cdot 10^4 \lambda / T_i(o), 1)$.
  Run Storing$(G_i, \alpha, 1, 0.1\delta/L)$ on a sub-stream $\{((p'_1, 1), \pm), ((p'_2, 1), \pm), \ldots\}$ in parallel.
    ▷ Storing is defined in Algorithm 27.3. Here p'_j satisfies $h_i(p'_j) = 1$.
  If Storing returns **FAIL**, output **FAIL**.
  Let $\gamma \leftarrow \epsilon/(40^2 Ld^3)$. ▷ Threshold for discarding levels
  Let $h'_i : [\Delta]^d \to \{0, 1\}$ be a λ-wise independent hash function.
    ▷ $\forall p \in [\Delta]^d, h'_i(p) = 1$ w.p. $\min(4 \cdot 10^4 \epsilon^{-2}\gamma^{-1}\lambda / T_i(o), 1)$.
  Run Storing$(G_i, \alpha', 1, 0.1\delta/L)$ on sub-stream $\{((p''_1, 1), \pm), ((p''_2, 1), \pm), \ldots\}$ in parallel.
    ▷ Storing is defined in Algorithm 27.3. Here p''_j satisfies $h'_i(p''_j) = 1$.
  If Storing returns **FAIL**, output **FAIL**.
  Let $\mathcal{C}_i, f_i, S_i \leftarrow$ Storing$(G_i, \alpha, 1, 0.1\delta/L)$ in line 27.4. Let $\widehat{f}(C) = f_i(C) \cdot \min\{T_i(o)/(4 \cdot 10^4\lambda), 1\}$.
    ▷ Use $\widehat{f}(C)$ as an estimator for $|C \cap Q|$ and follow Algorithm 27.1 to determine whether C is marked as heavy, crucial or nothing. (And conceptually compute $Q_0, \ldots, Q_L$ for analysis.)
  Let $\mathcal{C}'_i, f'_i, S'_i \leftarrow$ Storing$(G_i, \alpha', 1, 0.1\delta/L)$ in line 27.4.
  Let $\widehat{q}_i = \min\left\{\epsilon^2\gamma T_i(o)/(4 \cdot 10^4\lambda) \cdot \sum_{C \in \mathcal{C}'_i : C \text{ is crucial}} f'_i(C), 1\right\}$.
end for
Output: $\widehat{q}_0, \widehat{q}_1, \ldots, \widehat{q}_L$ and $\widehat{f} : \bigcup_{i=0}^{L} G_i \to \mathbb{R}_+$

Now let us analyze Algorithm 27.4. We need the following high concentration bound in our analysis.

Theorem 27.6.3 ([BR94]). *Let λ be an even integer, and let X be the sum of n λ-wise*

independent random variables taking values in $[0,1]$. *Let* $\mu = \mathbb{E}[X]$ *and* $a > 0$. *Then we have*

$$\Pr\left[|X-\mu| > a\right] \leq 8 \cdot \left(\frac{\lambda\mu + \lambda^2}{a^2}\right)^{\lambda/2}.$$

Lemma 27.6.4 (Samples from each cell)**.** *In* PointsEstimation(o, ϵ, δ) *(Algorithm 27.4), with probability at least* $1 - \delta/10$, $\forall i \in \{0, 1, \ldots, L\}$ *with* $T_i(o) \geq 4 \cdot 10^4\lambda$, $\forall C \in G_i$, *we have either*

$$\sum_{p \in C \cap Q} h_i(p) \in |C \cap Q| \cdot \frac{4 \cdot 10^4\lambda}{T_i(o)} \pm 4 \cdot 10^3\lambda$$

or

$$\sum_{p \in C \cap Q} h_i(p) \in |C \cap Q| \cdot \frac{4 \cdot 10^4\lambda}{T_i(o)} \cdot (1 \pm 0.01).$$

Proof. Consider a cell $C \in G_i$. If $|C \cap Q| \leq T_i(o)$, then $\mu = \mathbb{E}\left[\sum_{p \in C \cap Q} h_i(p)\right] = 4 \cdot 10^4\lambda |C \cap Q|/T_i(o) \leq 4 \cdot 10^4\lambda$. According to Theorem 27.6.3, we have

$$\Pr\left[\left|\sum_{p \in C \cap Q} h_i(p) - \mu\right| > 4 \cdot 10^3\lambda\right] \leq 8 \cdot \left(\frac{4 \cdot 10^4\lambda^2 + \lambda^2}{(4 \cdot 10^3\lambda)^2}\right)^{\lambda/2} \leq 8 \cdot (1/2)^{\lambda/2} \leq (\delta/\Delta^d)^5.$$

If $|C \cap Q| > T_i(o)$, then $\mu = \mathbb{E}\left[\sum_{p \in C \cap Q} h_i(p)\right] = 4 \cdot 10^4\lambda |C \cap Q|/T_i(o) > 4 \cdot 10^4\lambda$. According to Theorem 27.6.3, we have

$$\Pr\left[\left|\sum_{p \in C \cap Q} h_i(p) - \mu\right| > 0.01\mu\right] \leq 8 \cdot \left(\frac{\lambda\mu + \lambda^2}{(0.01\mu)^2}\right)^{\lambda/2} \leq 8 \cdot (1/2)^{\lambda/2} \leq (\delta/\Delta^d)^5.$$

By taking union bound over all $i \in \{0, 1, \ldots, L\}$ and all the cells in G_i, the claim is proved. □

Lemma 27.6.5 (Estimating the number of points in each cell)**.** *If* PointsEstimation(o, ϵ, δ) *(Algorithm 27.4) does not output* ***FAIL****, then with probability at least* $1 - \delta/10$, $\forall i \in \{0, 1, \ldots, L\}, C \in G_i$, *either* $\widehat{f}(C) \in |C \cap Q| \pm 0.1T_i(o)$ *or* $\widehat{f}(C) \in (1 \pm 0.01)|C \cap Q|$.

Proof. Suppose PointsEstimation(o, ϵ, δ) does not output **FAIL**. According to Lemma 27.6.2, $\forall i \in \{0, 1, \ldots, L\}$ and $\forall C \in G_i$, $f_i(C) = \sum_{p \in C \cap Q} h_i(p)$. If $T_i(o) \le 4 \cdot 10^4 \lambda$, then $\widehat{f}(C) = f_i(C) = \sum_{p \in C \cap Q} h_i(p) = |C \cap Q|$.

Due to Lemma 27.6.4, with probability at least $1 - \delta/10$, $\forall i \in \{0, 1, \ldots, L\}$ with $T_i(o) > 4 \cdot 10^4 \lambda$ and $\forall C \in G_i$, either $f_i(C) \in |C \cap Q| \cdot \frac{4 \cdot 10^4 \lambda}{T_i(o)} \pm 4 \cdot 10^3 \lambda$ or $f_i(C) \in |C \cap Q| \cdot \frac{4 \cdot 10^4 \lambda}{T_i(o)} \cdot (1 \pm 0.01)$. Thus, either $\widehat{f}(C) \in |C \cap Q| \pm 0.1 T_i(o)$ or $\widehat{f}(C) \in (1 \pm 0.01)|C \cap Q|$. □

Lemma 27.6.6 (Samples from each Q_i)**.** *In* PointsEstimation(o, ϵ, δ) *(Algorithm 27.4), with probability at least* $1 - \delta/10$, $\forall i \in \{0, 1, \ldots, L\}$ *with* $T_i(o) \ge 4 \cdot 10^4 \epsilon^{-2} \gamma^{-1} \lambda$, $\forall C \in G_i$, *either*

$$\sum_{p \in Q_i} h_i'(p) \in |Q_i| \cdot \frac{4 \cdot 10^4 \epsilon^{-2} \gamma^{-1} \lambda}{T_i(o)} \pm 4 \cdot 10^3 \epsilon^{-1} \lambda$$

or

$$\sum_{p \in Q_i} h_i'(p) \in |Q_i| \cdot \frac{4 \cdot 10^4 \epsilon^{-2} \gamma^{-1} \lambda}{T_i(o)} \cdot (1 \pm 0.01\epsilon).$$

Proof. If $|Q_i| \le \gamma T_i(o)$, then $\mu = \mathbb{E}\left[\sum_{p \in Q_i} h_i'(p)\right] = 4 \cdot 10^4 \epsilon^{-2} \gamma^{-1} \lambda |Q_i| / T_i(o) \le 4 \cdot 10^4 \epsilon^{-2} \lambda$. According to Theorem 27.6.3, we have

$$\Pr\left[\left|\sum_{p \in Q_i} h_i'(p) - \mu\right| > 4 \cdot 10^3 \epsilon^{-1} \lambda\right] \le 8 \cdot \left(\frac{4 \cdot 10^4 \epsilon^{-2} \lambda^2 + \lambda^2}{(4 \cdot 10^3 \epsilon^{-1} \lambda)^2}\right)^{\lambda/2} \le 8 \cdot (1/2)^{\lambda/2} \le (\delta/\Delta^d)^5.$$

If $|Q_i| > \gamma T_i(o)$, then $\mu = \mathbb{E}\left[\sum_{p \in Q_i} h_i'(p)\right] = 4 \cdot 10^4 \epsilon^{-2} \gamma^{-1} \lambda |Q_i| / T_i(o) > 4 \cdot 10^4 \epsilon^{-2} \lambda$. According to Theorem 27.6.3, we have

$$\Pr\left[\left|\sum_{p \in Q_i} h_i'(p) - \mu\right| > 0.01\epsilon\mu\right] \le 8 \cdot \left(\frac{\lambda\mu + \lambda^2}{(0.01\epsilon\mu)^2}\right)^{\lambda/2} \le 8 \cdot (1/2)^{\lambda/2} \le (\delta/\Delta^d)^5.$$

By taking union bound over all $i \in \{0, 1, \ldots, L\}$, the claim is proved. □

Lemma 27.6.7 ($\widehat{q}_i$ can estimate $|Q_i|$ well)**.** *If* PointsEsitmation(o, ϵ, δ) *(Algorithm 27.4) does not output* ***FAIL****, then with probability at least* $1 - \delta/10$*,* $\forall i \in \{0, 1, \ldots, L\}$*, either* $\widehat{q}_i \in |Q_i| \pm 0.1\epsilon\gamma T_i(o)$ *or* $\widehat{q}_i \in (1 \pm 0.01\epsilon)|Q_i|$*.*

Proof. Suppose PointsEstimation(o, ϵ, δ) does not output **FAIL**. According to Lemma 27.6.2, $\forall i \in \{0, 1, \ldots, L\}$, $f_i'(C) = \sum_{p \in Q_i} h_i'(p)$. If $T_i(o) \le 4 \cdot 10^4 \epsilon^{-2}\gamma^{-1}\lambda$, then $\widehat{q}_i = \sum_{C \in G_i : C \text{ is crucial}} f_i'(C) = \sum_{p \in Q_i} h_i'(p) = |Q_i|$.

Due to Lemma 27.6.6, with probability at least $1 - \delta/10$, $\forall i \in \{0, 1, \ldots, L\}$ with $T_i(o) > 4 \cdot 10^4 \epsilon^{-2}\gamma^{-1}\lambda$, either

$$\sum_{C \in G_i : C \text{ is crucial}} f_i'(C) \in |Q_i| \cdot \frac{4 \cdot 10^4 \epsilon^{-2}\gamma^{-1}\lambda}{T_i(o)} \pm 4 \cdot 10^3 \epsilon^{-1}\lambda$$

or

$$\sum_{C \in G_i : C \text{ is crucial}} f_i'(C) \in |Q_i| \cdot \frac{4 \cdot 10^4 \epsilon^{-2}\gamma^{-1}\lambda}{T_i(o)} \cdot (1 \pm 0.01\epsilon).$$

Thus, either $\widehat{q}_i \in |Q_i| \pm 0.1\epsilon\gamma T_i(o)$ or $\widehat{q}_i \in (1 \pm 0.01\epsilon)|Q_i|$. □

Lemma 27.6.8 (Number of points sampled from non-center cells)**.** *In* PointsEsitmation(o, ϵ, δ) *(Algorithm 27.4), with probability at least* $1 - \delta/10$*,* $\forall i \in \{0, 1, \ldots, L\}$*, we have*

$$\sum_{\text{non-center cell } C \in G_i} \sum_{p \in C \cap Q} h_i(p) \le 4 \cdot 10^3 \lambda + 1.01 \cdot \frac{4 \cdot 10^4 \lambda}{T_i(o)} \sum_{\text{non-center cell } C \in G_i} |C \cap Q|$$

and

$$\sum_{\text{non-center cell } C \in G_i} \sum_{p \in C \cap Q} h_i'(p) \le 4 \cdot 10^3 \epsilon^{-1}\lambda + 1.01 \cdot \frac{4 \cdot 10^4 \epsilon^{-2}\gamma^{-1}\lambda}{T_i(o)} \sum_{\text{non-center cell } C \in G_i} |C \cap Q|.$$

Proof. The proof is exactly the same as the proofs of Lemmas 27.6.4 and 27.6.6. □

Lemma 27.6.9. $\forall i \in \{0, 1, \ldots, L\}$,

$$\sum_{\text{non-center cell } C \in G_i} \frac{|C \cap Q|}{T_i(o)} \leq 400k \cdot (\mathrm{OPT}/o).$$

Proof.

$$\begin{aligned}&\sum_{\text{non-center cell } C \in G_i} |C \cap Q| \\ \leq &\frac{\mathrm{OPT}}{(g_i/(2d))^2} = 400kT_i(o) \cdot \frac{\mathrm{OPT}}{o}.\end{aligned}$$

□

Lemma 27.6.10 (The success probability)**.** *Condition on the number of center cells of all the grids is at most* $100kL$*. If* $o \in (\mathrm{OPT}/16, \mathrm{OPT}]$*, then* PointsEstimation(o, ϵ, δ) *(Algorithm 27.4) does not output* ***FAIL*** *with probability at least* $1 - 3\delta/10$*.*

Proof. Let $o \geq \mathrm{OPT}/16$, according to Lemma 27.6.9 and Lemma 27.6.8, with probability at least $1 - \delta/10$, $\forall i \in \{0, 1, \ldots, L\}$, we have

$$\sum_{\text{non-center cell } C \in G_i} \sum_{p \in C \cap Q} h_i(p) \leq 4 \cdot 10^3 \lambda + 1.01 \cdot 4 \cdot 10^4 \lambda \cdot 6400k \leq 10^{11} kdL \log(1/\delta)$$

and

$$\sum_{\text{non-center cell } C \in G_i} \sum_{p \in C \cap Q} h_i'(p) \leq 4 \cdot 10^3 \epsilon^{-1} \lambda + 1.01 \cdot 4 \cdot 10^4 \epsilon^{-2} \gamma^{-1} \lambda \cdot 6400k \leq 10^{15} \cdot \epsilon^{-3} kL^2 d^4.$$

Since the number of center cells is at most $100kL$, the total number of cells which contains some p with $h_i(p) = 1$ is at most $10^{12} kdL \log(1/\delta) \leq \alpha$, and the total number of cells which contains some p with $h_i'(p) = 1$ is at most $10^{16} \epsilon^{-3} kL^2 d^4 \leq \alpha'$. According to Lemma 27.6.2, with probability at least $1 - 2\delta/10$, none the call of Storing will return **FAIL**. Thus the overall probability that Algorithm 27.4 does not output **FAIL** is at last $1 - 3\delta/10$. □

Lemma 27.6.11 (Space of Algorithm 27.4)**.** PointsEstimation(o, ϵ, δ) *(Algorithm 27.4) uses space at most* $O(k\epsilon^{-3}L^4d^5 \cdot \log^2(kLd/(\epsilon\delta)))$ *bits.*

Proof. The total space used is dominated by the space needed to run $L+1$ copies of Storing$(G_i, \alpha', 1, 0.1\delta/L)$ in line 27.4 of Algorithm 27.4. According to Lemma 27.6.2, the total space needed is $O(L \cdot \alpha' dL \log^2(L\alpha'/\delta)) = O(k\epsilon^{-3}L^4d^5 \cdot \log^2(kLd/(\epsilon\delta)))$ bits. □

27.6.3 Sensitivity Sampling over a Dynamic Stream

Since using Algorithm 27.4 we can estimate the number of points in each cell and the size of each Q_i, the only remaining thing for simulating Algorithm 27.2 is to draw samples based on their sensitivity upper bounds. In Algorithm 27.5, we show how to achieve this in a dynamic stream.

Now we analyze Algorithm 27.5.

Fact 27.6.12. *If* Sampling(o, ϵ, δ) *(Algorithm 27.5) does not output* ***FAIL****, then line 27.5 can be implemented, and* p *is a uniform sample drawn from* Q_i*.*

Proof. Although Q_i cannot be stored explicitly, $\forall p \in Q$, we are able to determine whether $p \in Q_i$ since we can use $\widehat{f}$ to find all the crucial cells and check whether p is in a crucial cell of G_i.

Suppose Sampling(o, ϵ, δ) does not output **FAIL**. According to Lemma 27.6.2 and the condition in line 27.5, $\forall j \in [\widehat{m}]$, we have $\{(p, j) \mid p \in Q_i, h_{i,j}(p) = 1\} \subseteq S_i$. Since $\forall x, y \in Q_i$, $\Pr[h_{i,j}(x) = 1] = \Pr[h_{i,j}(y) = 1]$, then the sample p in line 27.5 is drawn uniformly from Q_i. □

Algorithm 27.5 Sensitivity sampling over a dynamic stream

SAMPLING(o, ϵ, δ):
Input: a point set $Q \subseteq [\Delta]^d$ described by a stream $\{(p_1, \pm), (p_2, \pm), \ldots\}$
Run POINTSESTIMATION$(o, \epsilon, \delta/2)$ in parallel on the input stream. If it returns **FAIL**, output **FAIL**.
$\forall i \in \{0, 1, \ldots, L\}$, $T_i(o) \leftarrow (d/g_i)^2 \cdot o/k \cdot 1/100$. ▷ Threshold for heaviness (Algorithm 27.1).
$\widehat{m} \leftarrow \Theta\left(k\epsilon^{-3}L^4d^7 \log\left(\frac{dLk}{\delta}\right) \cdot \frac{1}{\delta}\right)$. ▷ $\widehat{m}$ hash functions needed for m independent samples.
$\lambda \leftarrow 10\lceil(dL + \log(1/\delta) + 1)\rceil$. ▷ λ is the independence parameter.
$\forall i \in \{0, 1, \ldots, L\}$, choose $h_{i,1}, h_{i,2}, \ldots, h_{i,\widehat{m}} : [\Delta]^d \to \{0, 1\}$.
▷ $\forall j \in [\widehat{m}]$, $h_{i,j}$ is λ-wise independent, $\forall p \in [\Delta]^d$, $h_{i,j}(p) = 1$ w.p. $\min\left\{1/(10^4 kLT_i(o)), 1\right\}$.
$\alpha \leftarrow \Theta(k\epsilon^{-3}L^3d^7 \log(dLk/\delta)\delta^{-1})$, $\beta \leftarrow \Theta(\epsilon^{-3}L^3d^7 \log(dLk/\delta)\delta^{-1})$. ▷ α, β: for STORING.
For $i \in \{0, 1, \ldots, L\}$, run STORING$(G_i, \alpha, \beta, 0.1\delta/L)$ (Algorithm 27.3) in parallel.
▷ Each instance is run on a new stream obtained by splitting each operation $(p_t, \pm)$ from the original input stream into a set of new operations $\{((p_t, j), \pm) \mid j \in [\widehat{m}], h_{i,j}(p_t) = 1\}$.
If any STORING returns **FAIL**, output **FAIL**.

Output: the set S

Lemma 27.6.13 (Correctness of Algorithm 27.5)**.** *Suppose $o \in (0, \mathrm{OPT}]$. If* SAMPLING(o, ϵ, δ) *(Algorithm 27.5) does not output **FAIL**, then with probability at least $1 - \delta/5$, the output S by* SAMPLING(o, ϵ, δ) *is an ϵ-coreset for Q. Furthermore, the size $|S|$ is at most $O(k\epsilon^{-2}L^2d^4 \log(kLd) \cdot (\mathrm{OPT}/o + 1))$.*

Proof. Due to Lemma 27.6.5 and Lemma 27.6.7, with probability at least $1-\delta/10$, $\forall C \in \bigcup_{i=0}^{L} G_i$, either $\widehat{f}(C) \in |C \cap Q| \pm 0.1T_i(o)$ or $\widehat{f}(C) \in (1 \pm 0.01)|C \cap Q|$ and $\forall i \in \{0, 1, \ldots, L\}$, either $\widehat{q}_i \in |Q_i| \pm 0.1\epsilon\gamma T_i(o)$ or $\widehat{q}_i \in (1 \pm 0.01\epsilon)|Q_i|$, where $Q_0, Q_1, \ldots, Q_L$ are defined by using the estimation $\widehat{f}(\cdot)$ (Algorithm 27.1 or Algorithm 27.4). According to Fact 27.6.12, the sampling procedure can be implemented. Then by Theorem[6] 27.3.1, with probability at least $1-\delta/10$, the output set S is an ϵ-coreset for Q. By taking union bound, with probability $1-\delta/5$, the set S is an ϵ-coreset for Q. □

Now let us consider the success probability of Algorithm 27.5. Since we know the success probability of PointsEstimation$(o, \epsilon, \delta/2)$ in line 27.5 of Algortihm 27.5 and the success probability of Storing$(G_i, \alpha, \beta, 0.1\delta/L)$ in line 27.5, we only need to analyze the success probability in line 27.5 of Algorithm 27.5. To make line 27.5 succeed, we need to find enough samples from Q_i, i.e., we hope that $\sum_{j=1}^{\widehat{m}} \mathbf{1}(|\{p \in Q_i \mid h_{i,j}(p) = 1\}| > 0)$ is large. In the following analysis, we will show that $\sum_{j=1}^{\widehat{m}} \mathbf{1}(|\{p \in Q_i \mid h_{i,j}(p) = 1\}| > 0)$ is large. First, we show that the number of samples drawn from level i is bounded.

Lemma 27.6.14 (Number of samples from each level)**.** *Let I be the set computed in* Sampling(o, ϵ, δ) *(Algortihm 27.5). With probability at least $1-\delta/10$, $\forall i \in I$, the number of times that i is chosen in line 27.5 of Algorithm 27.5 is at most*

$$O\left(\epsilon^{-2} L d^4 \log(t'/\delta) \cdot \frac{L}{\delta} \cdot \frac{\widehat{q}_i}{T_i(o)}\right).$$

Proof. For $i \in I$, the expected number of times that i is chosen is $O(m \cdot \widehat{q}_i \cdot d^3/T_i(o)/t')$. By Markov's inequality, with probability at least $1-\delta/(20L)$, the number of times that i

[6]The proof is slightly different since Theorem 27.3.1 only claims a constant success probability. See Section 27.3.3 for the detailed proof of Theorem 27.3.1.

is chosen in line 27.5 of Algorithm 27.5 is at most $O\left(\epsilon^{-2} L d^4 \log(t'/\delta) \cdot \frac{L}{\delta} \cdot \frac{\widehat{q}_i}{T_i(o)}\right)$. By taking union bound over all $i \in I$, we complete the proof. □

Lemma 27.6.15 (Bounding t')**.** *Consider $o \geq \mathrm{OPT}/16$. Condition on $\widehat{f} : \bigcup_{i=0}^{L} G_i \to \mathbb{R}_+$ (in Algorithm 27.5) is good (Lemma 27.6.4), $\widehat{q}_0, \widehat{q}_1, \ldots, \widehat{q}_L$ (in Algorithm 27.5) are good (Lemma 27.6.6), and the number of center cells is at most $100kL$, then we have $t' \leq 10^6 d^3 Lk$.*

Proof. We have

$$\begin{aligned}
t' &= \sum_{i \in I} \widehat{q}_i \cdot 10d^3/T_i(o) \\
&\leq \sum_{i \in I} |Q_i| \cdot 20d^3/T_i(o) \\
&\leq \sum_{i=0}^{L} |Q_i| \cdot 20d^3/T_i(o) \\
&\leq 2 \cdot 4000 d^3 Lk \cdot 20 \\
&\leq 10^6 d^3 Lk,
\end{aligned}$$

where the first inequality follows by $\forall i \in I, \widehat{q}_i \geq \gamma T_i(o)$ and either $\widehat{q}_i \in |Q_i| \pm 0.1\epsilon\gamma T_i(o)$ or $\widehat{q}_i \in (1 \pm 0.01\epsilon)|Q_i|$, the second inequality follows by $I \subseteq \{0, 1, \ldots, L\}$, the third inequality follows by Lemma 27.3.8 and $o \geq \mathrm{OPT}/16$. □

Lemma 27.6.16 (Number of crucial points in each level)**.** *Consider $o \geq \mathrm{OPT}/16$. Conditioning on $\widehat{f} : \bigcup_{i=0}^{L} G_i \to \mathbb{R}_+$ (in Algorithm 27.5) is good (Lemma 27.6.5) and the number of center cells is at most $100kL$, we have:*

$$\frac{|Q_i|}{T_i(o)} \leq 7000kL.$$

Proof. We have

$$\begin{aligned}\frac{|Q_i|}{T_i(o)} &= \sum_{\text{center crucial cell } C\in G_i} \frac{|C\cap Q|}{T_i(o)} + \sum_{\text{non-center crucial cell } C\in G_i} \frac{|C\cap Q|}{T_i(o)} \\ &\leq 110kL + 400k(\mathrm{OPT}\,/o) \\ &\leq 7000kL,\end{aligned}$$

where the first inequality follows by that the number of center cells is at most $100kL$, the number points in a crucial cell is at most $1.1T_i(o)$ and Lemma 27.6.9. □

Lemma 27.6.17 (The number of samples is large)**.** *Consider $o \geq \mathrm{OPT}\,/16$. Conditioning on $\widehat{f} : \bigcup_{i=0}^{L} G_i \to \mathbb{R}_+$ (in Algorithm 27.5) is good (Lemma 27.6.4), $\widehat{q}_0, \widehat{q}_1, \ldots, \widehat{q}_L$ (in Algorithm 27.5) are good (Lemma 27.6.6), and the number of center cells is at most $100kL$, with probability at least $1 - \delta/10$, $\forall i \in I$, we have:*

$$\sum_{j=1}^{\widehat{m}} \mathbf{1}(|\{p \in Q_i \mid h_{i,j}(p) = 1\}| > 0) \geq \Omega\left(\epsilon^{-2} Ld^4 \log\left(\frac{dLk}{\delta}\right) \cdot \frac{L}{\delta} \cdot \frac{\widehat{q}_i}{T_i(o)}\right).$$

Proof. Consider a fixed $i \in I$. $\forall j \in [\widehat{m}]$, by union bound, we have

$$\Pr_{h_{i,j}}[\exists p \in Q_i, h_{i,j}(p) = 1] \leq \frac{|Q_i|}{10^4 kLT_i(o)} < 1,$$

where the inequality follows by Lemma 27.6.16. Thus $\lceil 10^4 kLT_i(o)/|Q_i|\rceil \leq 2\cdot 10^4 kLT_i(o)/|Q_i|$. Let $b = 10 \cdot \lceil 10^4 kLT_i(o)/|Q_i|\rceil$. Let $r = \lfloor \widehat{m}/b \rfloor \geq \widehat{m} \cdot |Q_i|/(2 \cdot 10^5 kLT_i(o)) - 1$. Since $i \in I$, we have $|Q_i|/T_i(o) \geq \frac{1}{2}\gamma$. Since $\widehat{m} \geq 10^9 kL/\gamma$, we have $r \geq \widehat{m}/(4 \cdot 10^5 kL) \cdot |Q_i|/T_i(o)$. For $s \in [r]$, we can define a random variable Y_s,

$$Y_s = \sum_{j=(s-1)\cdot b+1}^{s\cdot b} \sum_{p\in Q_i} h_{i,j}(p).$$

We have $\mathbb{E}[Y_s] = b \cdot |Q_i|/(10^4 kLT_i(o))$. Thus, $E[Y_s] \in [10, 20]$. Since Y_s is a sum of several (at least) pairwise independent unit random variables, $\mathbb{V}[Y_s] \leq 20$. Thus, by Chebyshev's inequality, we have

$$\Pr\left[|Y_s - \mathbb{E}[Y_s]| \geq 9\right] \leq 20/81 \leq 0.25.$$

Define X_s be the random variable such that $X_s = \mathbf{1}(Y_s \geq 1)$. Then $\mathbb{E}\left[\sum_{s\in[r]} X_s\right] \geq 0.75r$. By Chernoff bound, we know that

$$\Pr\left[\sum_{s\in[r]} X_s \leq 0.5r\right] \leq 2^{-r/20} \leq 0.01\delta/L,$$

where the last inequality follows by $r \geq \widehat{m}/(4 \cdot 10^5 kL) \cdot \gamma/2 \geq 20\log(100L/\delta)$.

Since $\widehat{m}$ is sufficiently large, i.e.,

$$\widehat{m} \geq \Omega\left(k\epsilon^{-2}L^3d^4 \log\left(\frac{dLk}{\delta}\right) \cdot \frac{1}{\delta\gamma}\right) \geq \Omega\left(k\epsilon^{-3}L^4d^7 \log\left(\frac{dLk}{\delta}\right) \cdot \frac{1}{\delta}\right),$$

we have

$$r \geq \widehat{m}/(4 \cdot 10^5 kL) \cdot |Q_i|/T_i(o) \geq \Omega\left(\epsilon^{-2}Ld^4 \log\left(\frac{dLk}{\delta}\right) \cdot \frac{L}{\delta} \cdot \frac{\widehat{q}_i}{T_i(o)}\right),$$

where the last inequality follows by $\widehat{q}_i = \Theta(|Q_i|)$. Notice that

$$\Pr\left[\sum_{j=1}^{\widehat{m}} \mathbf{1}(|\{p \in Q_i \mid h_{i,j}(p) = 1\}| > 0) \geq 0.5r\right] \geq \Pr\left[\sum_{s\in[r]} X_s \geq 0.5r\right] \geq 1 - 0.01\delta/L.$$

Thus, with probability at least $1 - 0.01\delta/L$,

$$\sum_{j=1}^{\widehat{m}} \mathbf{1}(|\{p \in Q_i \mid h_{i,j}(p) = 1\}| > 0) \geq \Omega\left(\epsilon^{-2}Ld^4 \log\left(\frac{dLk}{\delta}\right) \cdot \frac{L}{\delta} \cdot \frac{\widehat{q}_i}{T_i(o)}\right).$$

By taking the union bound over $i \in I$, we complete the proof. □

Lemma 27.6.18 (Sampling stage succeeds)**.** *Consider $o \geq \mathrm{OPT}/16$. Conditioning on $\widehat{f} : \bigcup_{i=0}^{L} G_i \to \mathbb{R}_+$ (in Algorithm 27.5) is good (Lemma 27.6.4), $\widehat{q}_0, \widehat{q}_1, \ldots, \widehat{q}_L$ (in Algorithm 27.5) are good (Lemma 27.6.6), and the number of center cells is at most $100kL$, if* SAMPLING(o, ϵ, δ) *does not output* ***FAIL*** *before line 27.5 of Algorithm 27.5, then with probability at least $1 - \delta/5$, it will not output* ***FAIL****.*

Proof. According to Lemma 27.6.14 and Lemma 27.6.15, with probability at least $1 - \delta/10$, $\forall i \in I$, the sampling procedure will not request too many samples from level i. According to Lemma 27.6.17, with probability at least $1 - \delta/10$, the number of samples needed for each level $i \in I$ is enough. Thus, with probability at least $1 - \delta/5$, the algorithm will not output **FAIL**. □

Lemma 27.6.19 (Samples can fit into the space)**.** *Suppose $o \geq \mathrm{OPT}/16$. Conditioning on $\widehat{f} : \bigcup_{i=0}^{L} G_i \to \mathbb{R}_+$ (in Algorithm 27.5) is good (Lemma 27.6.4), if the total number of center cells is at most $100kL$, with probability at least $1 - \delta/5$,* SAMPLING(o, ϵ, δ) *(Algorithm 27.5) will not output* ***FAIL*** *in line 27.5 nor line 27.5.*

Proof. Consider $i \in \{0, 1, \ldots, L\}$ and a cell $C \in G_i$ which is marked as crucial by POINTSESTIMATION$(o, \epsilon, \delta/2)$.

$$\begin{aligned}\mathbb{E}\left[\sum_{j=1}^{\widehat{m}} \sum_{p \in C \cap Q} h_{i,j}(p)\right] &= \widehat{m} \cdot |C \cap Q|/(10^4 kLT_i(o)) \\ &\leq O(\epsilon^{-3} L^3 d^7 \log(dLk/\delta)\delta^{-1}).\end{aligned}$$

By Theorem 27.6.3,

$$\Pr\left[\sum_{j=1}^{\widehat{m}} \sum_{p \in C \cap Q} h_{i,j}(p) > \mathbb{E}\left[\sum_{j=1}^{\widehat{m}} \sum_{p \in C \cap Q} h_{i,j}(p)\right] + \epsilon^{-3} L^3 d^7 \log(dLk/\delta)\delta^{-1}\right] \leq (\delta/\Delta^d)^5.$$

Thus, by taking union bound, with probability at last $1-\delta/10$, $\forall i \in \{0,1,\ldots,L\}$, any cell $C \in G_i$ which is marked as crucial, the total number of points sampled in C is at most β. Thus, with probability at least $1-\delta/20$, SAMPLING(o,ϵ,δ) (Algorithm 27.5) will not output **FAIL** in line 27.5.

Consider $i \in \{0,1\ldots,L\}$. Let us analyze the number of cells in G_i which contain at least 1 sample points. The number of points which are not in the center cell is at most

$$\frac{\mathrm{OPT}}{(g_i/(2d))^2} \leq 400kT_i(o)\cdot \mathrm{OPT}/o \leq 6400kT_i(o).$$

Thus, the expected number of sampled points in non-center cell is at most $O(k\epsilon^{-3}L^3d^7\log(dLk/\delta)\cdot 1/\delta)$. Since the number of center cells is at most $100kL$, by Theorem 27.6.3, with probability at least $1-\delta/(100L)$, the number of cells in G_i which contain at least 1 sample points is $O(k\epsilon^{-3}L^3d^7\log(dLk/\delta)\cdot 1/\delta)$. By taking union bound over all $i \in \{0,1,\ldots,L\}$, with probability at least $1-\delta/20$, $\forall i \in \{0,1,\ldots,L\}$, the number of sampled cell in G_i is at most α.

Due to Lemma 27.6.2, with probability at least $1-\delta/10$, none of the STORING$(G_i,\alpha,\beta,0.1\delta/L)$ in line 27.5 of Algorithm 27.5 will output **FAIL**. By union bound over all the failure probabilities, we complete the proof. □

Lemma 27.6.20 (The overall success probability)**.** *Suppose* $o \geq \mathrm{OPT}/16$ *and the total number of center cells is at most* $100kL$*. With probability at least* $1-4\delta/5$*,* SAMPLING(o,ϵ,δ) *(Algorithm 27.5) will not output* ***FAIL****.*

Proof. Due to Lemma 27.6.10, POINTSESTIMATION$(o,\epsilon,\delta/2)$ in line 27.5 will not output **FAIL** with probability at least $1-3\delta/20$. By Lemma 27.6.5 and Lemma 27.6.6, with

probability at least $1-\delta/5$, $\forall i \in \{0,1,\ldots,L\}$, either $\widehat{q}_i \in |Q_i| \pm 0.1\epsilon\gamma T_i(o)$ or $\widehat{q}_i \in (1 \pm 0.01\epsilon)|Q_i|$, and $\forall C \in G_i$, either $\widehat{f}(C) \in |C \cap Q| \pm 0.1T_i(o)$ or $\widehat{f}(C) \in (1 \pm 0.01)|C \cap Q|$. Then by Lemma 27.6.19, with probability at least $1-\delta/5$, SAMPLING(o,ϵ,δ) will not output **FAIL** in line 27.5 nor line 27.5. Finally, according to Lemma 27.6.18, with probability at least $1-\delta/5$, the algorithm does not output **FAIL**. By taking union bound over all the bad events, with probability at least $1-3\delta/20-\delta/5-\delta/5-\delta/5 \geq 1-4\delta/5$, SAMPLING$(o,\epsilon,\delta)$ (Algorithm 27.5) will not output **FAIL**. □

Lemma 27.6.21 (Total space of Algorithm 27.5)**.** SAMPLING(o,ϵ,δ) *uses space at most* $O(k\epsilon^{-6}L^8d^{15}\delta^{-2}\cdot\log^4(kLd/(\epsilon\delta)))$ *bits.*

Proof. According to Lemma 27.6.11, POINTSESTIMATION$(o,\epsilon,\delta/2)$ in line 27.5 of Algorithm 27.5 takes the space $O(k\epsilon^{-3}L^4d^5\cdot\log(kLd/(\epsilon\delta)))$ bits. According to Lemma 27.6.2, line 27.5 takes the total space:

$$O(L\cdot\alpha\beta dL\cdot\log^2(\alpha\beta/\delta)) = O(k\epsilon^{-6}L^8d^{15}\delta^{-2}\cdot\log^4(kLd/(\epsilon\delta))).$$

□

27.6.4 The Final Algorithm

Finally, we use exponential search to enumerate the guesses o. In Algorithm 27.6, we show the details of how to run Algorithm 27.5 with different guesses in parallel. Our main theorem is the following.

Theorem 27.6.22. *Suppose a point set $Q \subseteq [\Delta]^d$ is given by a stream of insertion/deletion operations in the dynamic streaming model (Definition 27.2.1). Let $L = \log\Delta$. For given*

Algorithm 27.6 Coreset construction over a dynamic stream

1: DynamicCoreset(ϵ):
2: **input:** a point set $Q \subseteq [\Delta]^d$ described by a stream $\{(p_1, \pm), (p_2, \pm), \ldots\}$
3: Impose randomly shifted grids $G_{-1}, G_0, G_1, \ldots, G_L$ (Definition 27.3.1).
4: Run Distinct($10000k, 0.001$) (Lemma 27.6.1) over the input stream in parallel.
5: If line 27.6 does not output **FAIL**, we output the entire point set Q.
6: For each $u \in [2dL]$, let $o_u = 2^u \cdot 50k$ and run Sampling($o_u, \epsilon, 0.001/(dL)$) (Algorithm 27.5) over the input stream in parallel.
7: Set a threshold $h = \Theta(k\epsilon^{-2}L^2d^4 \log(kLd))$.
8: Find the smallest u^* such that Sampling($o_{u^*}, \epsilon, 0.001/(dL)$) in line 27.6 does not output **FAIL**, and the returned set S^* has size at most h, i.e., $|S^*| \leq h$.
9: If no such u^*, output **FAIL**. Otherwise, output S^* returned by Sampling($o_{u^*}, \epsilon, 0.001/(dL)$).

$\epsilon \in (0, 1/2)$, Algorithm 27.6 uses a single pass over the stream and on termination outputs a k-means ϵ-coreset S (Definition 27.2.3) for Q with probability at least 0.9. Furthermore, the size of the coreset is at most $O(k\epsilon^{-2}d^4L^2 \log(kdL))$. The total space used by the algorithm is $\widetilde{O}(k) \cdot \mathrm{poly}(dL/\epsilon)$ bits.

We divide the proof of Theorem 27.6.22 into the following two lemmas.

Lemma 27.6.23 (Correctness and success probability)**.** *With probability at least 0.9, DynamicCoreset(ϵ) (Algorithm 27.6) outputs an ϵ-coreset for Q and the size of the coreset is at most $O(k\epsilon^{-2}L^2d^4 \log(kLd))$.*

Proof. If $|Q| \leq 10000k$, then according to Lemma 27.6.1, with probability at least 0.999, the entire data set Q will be returned by line 27.6 in Algorithm 27.6.

Consider the case when $|Q| \geq 10000k$. According to Lemma 27.3.7, with probability at least 0.94, the total number of center cells is upper bounded by $100kL$. Now, we condition on this happens. Since $|Q| \geq 10000k$, we know that $\mathrm{OPT} \geq 1000k$. There exists $u \in [2dL]$ such that $o_u \in [\mathrm{OPT}/16, \mathrm{OPT}]$. According to Lemma 27.6.20, with probability

at least 0.999, SAMPLING$(o_u, \epsilon, 0.001/(dL))$ will not output **FAIL**. By Lemma 27.6.13, with probability at least 0.999, the set S returned by SAMPLING$(o_u, \epsilon, 0.001/(dL))$ is an ϵ-coreset and $|S| \leq O(k\epsilon^{-2}L^2d^4)$. Thus, with probability at least 0.998, DYNAMICCORESET(ϵ) (Algorithm 27.6) will not output **FAIL**. Consider another $u' < u$. If SAMPLING$(o_{u'}, \epsilon, 0.001/(dL))$ does not output **FAIL**, and the set S' returned has size at most h, then according to Lemma 27.6.13, with probability at least $1 - 0.001/(dL)$, S' is an ϵ-coreset for Q. By taking union bound over all the such u', then with probability at least 0.999, S^* returned by SAMPLING$(o_{u^*}, \epsilon, 0.001/(dL))$ is an ϵ-coreset for Q. By taking union bound over all the bad events, we complete the proof. □

Lemma 27.6.24 (Total space needed for Algortihm 27.6)**.** DYNAMICCORESET(ϵ) *(Algorithm 27.6) uses space at most* $O(k\epsilon^{-6}L^{11}d^{18}\log^4(kLd/\epsilon))$ *bits.*

Proof. DYNAMICCORESET(ϵ) (Algorithm 27.6) runs $\Theta(dL)$ copies of SAMPLING$(o_u, \epsilon, 0.001/(dL))$. By Lemma 27.6.21, the total space needed is

$$O(dL \cdot k\epsilon^{-6}L^8d^{15} \cdot (dL)^2 \cdot \log^4(kLd/\epsilon)) = O(k\epsilon^{-6}L^{11}d^{18}\log^4(kLd/\epsilon))$$

bits. □

Proof of Theorem 27.6.22. Lemma 27.6.23 shows the correctness and the success probability of the algorithm. Lemma 27.6.24 shows the total space needed by the algorithm. □

27.7 Why Do Previous Techniques Fail?

In this section, we describe some previous techniques in more detail and explain why they fail in our setting.

Uniform sampling method. [FIS05] is one of the early papers using sampling procedures to solve dynamic streaming geometric problems. They showed that it is possible to use point samples from a dynamic point set to solve several geometric problems, e.g., Euclidean Minimum Spanning Tree. However, they only showed how to implement *uniform* sampling by using counting distinct elements and subsampling procedure as subroutines. In our setting, we require different sampling probabilities for different points. Although the bottom-level uniform sampling scheme of ours is similar to theirs, our overall sampling method is more complicated.

Estimating the cost. [Ind04] used a critical observation to *estimate* the cost of k-median, that is: let Z be a set of centers and P be the point set, then $\text{cost}(Z,P) = \int_0^\infty |P - B(Z,r)|\mathrm{d}r$, where $B(Z,r)$ is the union of balls of radius r centered at all points in Z. Then this integration is approximated by a summation with logarithmic levels, i.e., $\int_0^\infty |P - B(Z,r)|\mathrm{d}r \approx \sum_{i=0}^{\infty} \left|P - B(Z,r^{(i+1)})\right| \cdot \left(r^{(i+1)} - r^{(i)}\right)$, where $r^{(i)} = O(\epsilon(1+\epsilon)^i)$. The critical part is to estimate $\left|P - B(Z,r^{(i)})\right|$. [Ind04] constructed a counting data structure based on grids with side length $O\left(r^{(i)}\right)$. Then every input point is snapped to a grid point. To obtain sufficiently accurate estimates for all $\left|P - B(Z,r^{(i)})\right|$, the data structure needs to query $|Z|/\epsilon^{O(d)}$ many grid points per Z. Such a data structure is implemented using pair-wise independent hash functions, and uses memory $|Z|/\epsilon^{O(d)}$. Notice that this method only

gives an *estimate* of the cost, and does not construct a coreset. In order to obtain a k-median solution, an exhaustive search is needed. Furthermore, this technique fails to extend to k-means which does not have an integration formula for the cost function.

Exponential size coreset. [FS05] constructed an ϵ-coreset of size $k\epsilon^{-O(d)}$ for k-means and k-median. They also used the same grid structure as we use. A cell is marked as "heavy" if the cell contains enough points such that moving all points in the cell to the center of this cell incurs too much error in the optimal cost of k-means/median. Since the side-lengths of cells decrease as level increases, the number of points required to have this effect becomes larger. Eventually, all cells are non-heavy after some level. As such we also have a tree of heavy cells. The coreset is constructed by looking at each heavy cell and assigning each point in its non-heavy children cells to its center. It turns out that if we want an ϵ-coreset, the threshold of non-heavy cells is exponential in d, i.e., each non-heavy cell in level i cannot contain more than $\widetilde{O}\left(\epsilon^{O(d)} \cdot \mathrm{OPT}/2^i\right)$ points. This small threshold gives rise to $\widetilde{O}\left(1/\epsilon^{O(d)}\right)$ many heavy cells.

Insertion-only streams. Many of the previous *insertion-only* streaming coreset construction algorithms (e.g., [FS12]) heavily depend on a "merge-reduce" technique, i.e. reading some points in the stream, constructing a coreset, reading another part, constructing a new coreset, and then merging the two coresets. This procedure is repeated until the stream ends. This technique works well in the insertion-only streaming model, but it fails immediately when deletions are allowed. Although [BFL16] gave a new framework other than merge-reduce, their algorithm relies on a non-deleting structure of data streams as well.

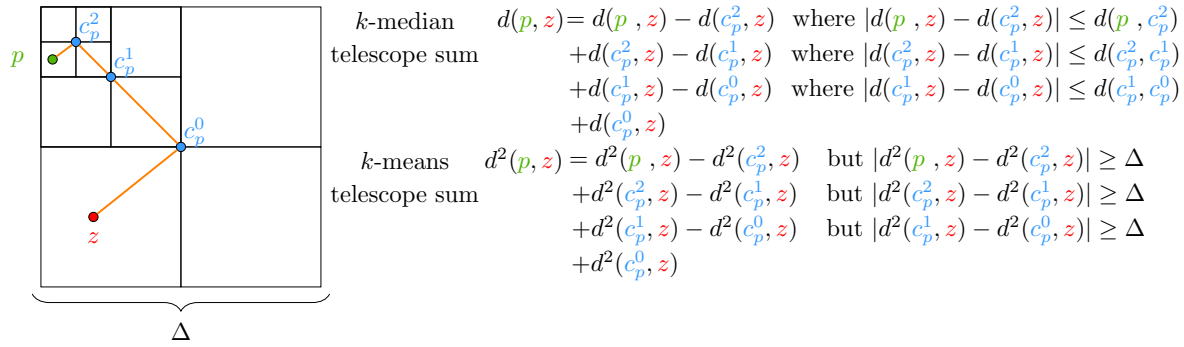

Figure 27.3: Telescope sum [BFL+17] fails for k-means. In the k-median problem, for a fixed set of centers Z, the total cost can be written as a telescope sum $\sum_{p\in P}(\mathrm{dist}(c_p^i, Z) - \mathrm{dist}(c_p^{i-1}, Z))$. For each piece, $|\mathrm{dist}(c_p^i, Z) - \mathrm{dist}(c_p^{i-1}, Z)|$ is always upper bounded by $\mathrm{dist}(c_p^{i-1}, c_p^i)$ which is independent from the choice of Z. However, in the k-means problem, the telescope sum of the total cost is $\sum_{p\in P}(\mathrm{dist}(c_p^i, Z)^2 - \mathrm{dist}(c_p^{i-1}, Z)^2)$. For each piece, the upper bound of $|\mathrm{dist}(c_p^i, Z)^2 - \mathrm{dist}(c_p^{i-1}, Z)^2|$ may depend on the location of Z, and it can be larger than Δ in the worst case.

Algorithm for k-median only. Although some k-median coreset construction techniques can be easily extended to k-means (see e.g. [FS12, BFL16]), those constructions can only be implemented in the insertion-only streaming model. [BFL+17] gave a k-median coreset construction in the dynamic streaming model, but their construction cannot be extended to k-means directly, as we explain now. Their k-median algorithm heavily relies on writing the cost of each point as a telescope sum. For example, we consider the 1-median problem. let z be a candidate center point and $p \in P$ be a point, then $\mathrm{dist}(p, z) = \mathrm{dist}(p, z) - \mathrm{dist}(c_p^{L-1}, z) + \mathrm{dist}(c_p^{L-1}, z) - \mathrm{dist}(c_p^{L-2}, z) + \cdots - \mathrm{dist}(c_p^0, z)$, where each c_p^i is the center of the cell in the i-th level containing p. Therefore, the total 1-median cost $\sum_{p\in P}\mathrm{dist}(p, z)$ of point set P on z can be split into L pieces, i.e., $\sum_{p\in P}(\mathrm{dist}(c_p^i, z) - \mathrm{dist}(c_p^{i-1}, z))$ for each $i \in [L]$. [BFL+17] estimated each of the L pieces by sampling points, i.e., let S^i be the samples in the i-th level, then the estimator of $\sum_{p\in P}(\mathrm{dist}(c_p^i, z) - \mathrm{dist}(c_p^{i-1}, z))$ is $\sum_{p\in S^i}(\mathrm{dist}(c_p^i, z) - \mathrm{dist}(c_p^{i-1}, z))/\zeta_p^i$ where ζ_p^i is the probability that point p is sampled. A crucial observation is that we have

$|\operatorname{dist}(c^i, z) - \operatorname{dist}(c^{i-1}, z)| \leq \Delta/2^i$ – the cell size in level i which is independent of the location of z. Using this nice upper bound on $|\operatorname{dist}(c^i, z) - \operatorname{dist}(c^{i-1}, z)|$, [BFL+17] applied Bernstein inequality to get high concentration of the estimator $\sum_{p \in S^i} (\operatorname{dist}(c_p^i, z) - \operatorname{dist}(c_p^{i-1}, z))/\zeta_p^i$ with only $\widetilde{O}(1/\epsilon^2)$ samples per level. However, this framework does not work for 1-means even though one can still write the telescope sum structure $\sum_p (\operatorname{dist}^2(c_p^i, z) - \operatorname{dist}^2(c_p^{i-1}, z))$ and can still setup an estimator $\sum_{p \in S^i} (\operatorname{dist}^2(c_p^i, z) - \operatorname{dist}^2(c_p^{i-1}, z))/\zeta_p^i$. But $|\operatorname{dist}^2(c_p^i, z) - \operatorname{dist}^2(c_p^{i-1}, z)|$ is not upper bounded by the cell size anymore. Instead, it depends on the location of z. For example, it can be as large as $|\operatorname{dist}^2(c_p^i, z) - \operatorname{dist}^2(c_p^{i-1}, z)| \geq \Delta$. See Figure 27.3. If we apply Bernstein inequality here, we will need too many samples to save any space.

Chapter 28

Convergence Result of one-hidden Layer Neural Network

We improve the over-parametrization size over the two beautiful results [Li and Liang' 2018] and [Du, Zhai, Poczos and Singh' 2019] in deep learning theory.

This part is based upon the following previous publication

- Zhao Song, Xin Yang

  Quadratic Suffices for Over-parametrization via Matrix Chernoff Bound.

  Manuscript 2019 [SY19]

28.1 Introduction

Over-parameterization theory for deep neural networks becomes extremely popular over the last few years. There is a long line (still growing very quickly) of work proving that (stochastic) gradient descent algorithm is able to find the global minimum if the network is wide enough [LL18, DZPS19, AZLS18, AZLS19, DLL+19, ZCZG18]. One fundamental question for over-parameterization is, how wide should the neural network be?

Formally speaking, the existing results show that as long as the width m is at least polynomial of number of input data n, then (S)GD-type algorithm can work in the following sense: first randomly pick a weight matrix to be the initialization point, update the weight matrix according to gradient direction over each iteration, and eventually find the global minimum. It is conjectured [Lee18] that $m = \Omega(n \operatorname{poly}(\log(n/\delta)))$ is the right answer, where δ is the failure probability. The randomness is from the random initialization and also algorithm itself, but not from data. There are other work relied on input data to be random [BG17, Tia17, ZSJ+17, Son17, LY17, ZSD17, DLT+18, GLM18, BJW19], however over-parameterization theory does not allow that assumption and it only needs to make very mild assumption on data, e.g. separable. The breakthrough result by Li and Liang [LL18] is the first one that is able to explain why the greedy algorithm works very well in practice for ReLU neural network from over-parameterization perspective. The state-of-the-art result for one-hidden-layer neural network with ReLU activation function is due to Du, Zhai, Poczos and Singh [DZPS19]. Their beautiful result proved that $m = \Omega(n^6 \operatorname{poly}(\log n, 1/\delta))$ is sufficient. We improve the result [DZPS19] from two perspectives : one is the dependence on failure probability, and the other is the dependence on the number of input data. More precisely, we show that $m = \Omega(n^4 \operatorname{poly}(\log(n/\delta)))$ is sufficient via a careful concentration analysis.

More interestingly, when the input data have certain property, we can improve the bound to $m = \Omega(n^2 \operatorname{poly}(\log(n/\delta)))$ via a more careful concentration analysis for random variables.

The study of concentration of sums of random variables dates back to Central Limit Theorems, the first modern concentration bounds were probably proposed by Bernstein [Ber24]. Chernoff bound is an extremely popular variant, which was introduced by Rubin and published by Chernoff [Che52]. Chernoff bound is a fundamental tool in Theoretical Computer Science and has been used in almost every randomized algorithm paper without even stating it. One common statement is the following: given a list of independent random variables $x_1, \cdots, x_m \in [0, 1]$ with mean μ, then

$$\Pr\left[\left|\frac{1}{m}\sum_{i=1}^{m} x_i - \mu\right| > \epsilon\right] \leq 2\exp(-\Omega(m\epsilon^2))$$

In many applications, we are not just dealing with scalar random variables. A natural generalization of the Chernoff bound appeared in the works of Rudelson [Rud99], Ahlswede-Winter [AW02], and Tropp [Tro12]. They proved that a similar concentration phenomenon is true even for matrix random variables. Given a list of independent complex Hermitian random matrices $X_1, \cdots, X_m \in \mathbb{C}^{n\times n}$ with mean μ and $\|X_i\| \leq 1$, $\forall i \in [m]$, then

$$\Pr\left[\left\|\frac{1}{m}\sum_{i=1}^{m} X_i - \mu\right\| > \epsilon\right] \leq 2n\exp(-\Omega(m\epsilon^2))$$

For a more detailed survey and recent progress on the topic Matrix Chernoff bound. We refer the readers to [Tro15, GLSS18, KS18].

In this work, we draw an interesting connection between deep learning theory and Matrix Chernoff bound : we can view the width of neural network as the number of independent random matrices.

28.1.1 Our Result

We start with the definition of Gram matrix, which can be found in [DZPS19].

Definition 28.1.1 (Data-dependent function H)**.** Given a collection of data $\{x_1, \cdots, x_n\} \subset \mathbb{R}^d$. For any vector $w \in \mathbb{R}^d$, we define symmetric matrix $H(w) \in \mathbb{R}^{n \times n}$ as follows

$$H(w)_{i,j} = x_i^\top x_j \mathbf{1}_{w^\top x_i \geq 0, w^\top x_j \geq 0}, \forall (i,j) \in [n] \times [n].$$

Then we define continuous Gram matrix $H^{\mathrm{cts}} \in \mathbb{R}^{n \times n}$ in the following sense

$$H^{\mathrm{cts}} = \mathop{\mathbb{E}}_{w \sim N(0,I)}[H(w)].$$

Similarly, we define discrete Gram matrix $H^{\mathrm{dis}} \in \mathbb{R}^{n \times n}$ in the following sense

$$H^{\mathrm{dis}} = \frac{1}{m} \sum_{r=1}^m H(w_r).$$

We use $N(0, I)$ to denote Gaussian distribution. We use $\mathbb{E}_w$ to denote $\mathbb{E}_{w \sim N(0,I)}$ and $\Pr_w$ to denote $\Pr_{w \sim N(0,I)}$. We introduce some mild data-dependent assumption. Without loss of generality, we can assume that $\|x_i\|_2 \leq 1$, $\forall i \in [n]$.

Assumption 28.1.1 (Data-dependent assumption)**.** *We made the following data-dependent assumption:*

1. *Let* $\lambda = \lambda_{\min}(\mathbb{E}_w[H(w)])$ *and* $\lambda \in (0, 1]$.
2. *Let* $\alpha \in [1, n]$ *and* $\gamma \in [0, 1)$ *be the parameter such that* [1]

$$\Pr_w \left[\left\| H(w) - \mathop{\mathbb{E}}_w[H] \right\| \leq \alpha \right] \geq 1 - \gamma.$$

[1] For simplicity, let us assume $\gamma = 0$.

3. Let $\beta \in [1, n^2]$ be the parameter such that

$$\left\| \mathop{\mathbb{E}}_{w} \left[\Big(H(w) - \mathop{\mathbb{E}}_{w}[H(w)] \Big) \Big(H(w) - \mathop{\mathbb{E}}_{w}[H(w)] \Big)^\top \right] \right\| \leq \beta.$$

4. Let $\theta \in [0, \sqrt{n}]$ be parameter such that

$$|x_i^\top x_j| \leq \theta / \sqrt{n}, \forall i \neq j.$$

The first assumption is from [DZPS19]. For more detailed discussion about that assumption, we refer the readers to [DZPS19]. The last assumption is similar to assumption in [AZLS18, AZLS19], where they assumed that for $i \neq j$, $\|x_i - x_j\|_2 \geq \theta'$. If we think of $\|x_i\|_2 = 1, \forall i \in [n]$, then we know that $(\theta')^2 \leq 2 - 2x_i^\top x_j$. It indicates $(\theta')^2 + 2\theta/\sqrt{n} \leq 2$. The second and the third assumption are motivated by Matrix Chernoff bound. The reason for introducing these Matrix Chernoff-type assumption is, the goal is to bound the spectral norm of the sums of random matrices in several parts of the proof. One way is to relax the spectral norm to the Frobenious norm, and bound each entry of the matrix, and finally union bound over all entries in the matrix. This could potentially lose a $\sqrt{n}$ factor compared to applying Matrix Chernoff bound. We feel these assumptions can indicate how the input data affect the over-parameterization size m in a more clear way.

We state our result for the concentration of sums of independent random matrices:

Proposition 28.1.2 (Informal of Theorem 28.5.1)**.** *Assume Part 1,2 and 3 of Assumption 28.1.1. If $m = \Omega((\lambda^{-2}\beta + \lambda^{-1}\alpha)\log(n/\delta))$, then*

$$\Pr_{w_1, \cdots, w_m \in N(0,I)}[\|H^{\mathrm{dis}} - H^{\mathrm{cts}}\|_2 \leq \lambda/4] \geq 1 - \delta.$$

Table 28.1: Summary of Convergence Result

Reference	m	λ	α	θ
[DZPS19]	$\lambda^{-4}n^6 \operatorname{poly}(\log n, 1/\delta)$	Yes	No	No
Theorem 28.1.3	$\lambda^{-4}n^4 \log^3(n/\delta)$	Yes	No	No
Theorem 28.1.4	$\lambda^{-4}n^3 \log^3(n/\delta) \cdot \alpha$	Yes	Yes	No
Theorem 28.1.5	$\lambda^{-4}n^2 \log^3(n/\delta) \cdot \alpha(\alpha + \theta^2)$	Yes	Yes	Yes

Proposition 28.1.2 is a direct improvement compared to Lemma 3.1 in [DZPS19], which requires $m = \Omega(\lambda^{-2}n^2 \log(n/\delta))$. Proposition 28.1.2 is better when input data points have some good properties, e.g., $\beta, \alpha = o(n^2)$. However the result in [DZPS19] always needs to pay n^2 factor, no matter what the input data points are.

We state our convergence result as follows:

Theorem 28.1.3 (Informal of Theorem 28.4.5)**.** *Assume Part 1 of Assumption 28.1.1. Let m denote the width of neural network, let n denote the number of input data points. If $m = \Omega(\lambda^{-4}n^4 \operatorname{poly}(\log(n/\delta)))$, then gradient descent is able to find the global minimum from a random initialization point with probability $1 - \delta$.*

Theorem 28.1.3 is a direct improvement compared to Theorem 4.1 in [DZPS19], which requires $m = \Omega(\lambda^{-4}n^6 \operatorname{poly}(\log n, 1/\delta))$.

If we also allow Part 2 of Assumption 28.1.1, we can slightly improve Theorem 28.1.3 from n^4 to n^3,

Theorem 28.1.4 (Informal of Theorem 28.5.5)**.** *Assume Part 1 and 2 of Assumption 28.1.1. If $m = \Omega(\lambda^{-4}n^3\alpha \operatorname{poly}(\log(n/\delta)))$, then gradient descent is able to find the global minimum from a random initialization point with probability $1 - \delta$.*

Except for m, Theorem 4.1 in [DZPS19] requires step size η to be $\Theta(\lambda/n^2)$. Theorem 28.1.4 only needs step size η to be $\Theta(\lambda/(\alpha n))$.

Further, if we also allow Part 4 of Assumption 28.1.1, we can slightly improve Theorem 28.1.3 from n^4 to n^2,

Theorem 28.1.5 (Informal of Theorem 28.6.4)**.** *Assume Part 1, 2 and 4 of Assumption 28.1.1. If $m = \Omega(\lambda^{-4} n^2 \alpha(\theta^2 + \alpha) \operatorname{poly}(\log(n/\delta)))$, the gradient descent is able to find the global minimum from a random initialization point with probability $1 - \delta$.*

28.1.2 Technical Overview

We follow the exact same optimization framework as Du, Zhai, Poczos and Singh [DZPS19]. We improve the bound on m by doing a careful concentration analysis for random variables without changing the high-level optimization framework.

We briefly summarize the optimization framework here: the minimal eigenvalue λ of H^{cts}, as introduced in [DZPS19], turns out to be closely related with the convergence rate. As time evolves, the weights w in the network may vary; however if w stay in a ball of radius R that only depends on the number of data n and λ, and particularly does not depend on the number of neurons m, then we are still able to lower bound the minimal eigenvalue of $H(w)$. On the other hand, we want to upper bound D, the actual move of w, with high probability. It turns out D is proportional to $\frac{1}{\sqrt{m}}$. We require $D < R$ in order to control the convergence rate. In this way we derive a lower bound of m.

In order to bound $\|H\|$, [DZPS19] relax it to Frobenius norm and then relax it to entry-wise L1 norm,

$$\|H\| \leq \|H\|_F \leq \|H\|_1.$$

Then they can bound each term of $H_{i,j}$ individually via Markov inequality.

One key observation is that $\|H\|_1$ is a quite loose bound for $\|H\|_F$, in the sense that $\|H\|_1 = \|H\|_F$ holds only if H contains at most 1 non-zero entry. This means we can work on the Frobenius norm directly, and we shall be able to obtain a tighter estimation. By definition of H, it can be written as a summation of m independent matrices $A_1, A_2, \cdots, A_m \in \mathbb{R}^{n \times n}$,

$$H = \frac{1}{m} \sum_{r=1}^{m} A_r$$

In order to bound $\|H\|_F$, for each i, j, we regard each H_{ij} as summation of m independent random variables, then apply Bernstein bound to obtain experiential tail bound on the concentration of H_{ij}. Finally, by taking a union bound over all the n^2 pairs we obtain a tighter bound for $\|H\|_F$.

We shall mention that $\|H\|_F$ is also a loose upper bound of $\|H\|$, i.e., $\|H\|_F = \|H\|$ only if H is a rank-1 matrix. Hence, if the condition number of H is small, which may happen as a property of the data, then we may benefit from bounding $\|H\|$ directly. We achieve this by apply matrix Chernoff bound, which states the spectral norm of summation of m independent matrices concentrates under certain conditions.

We shall stress that mutually independence plays a very important role in our argument. Throughout the whole paper we are dealing with summations of the form $\sum_{r=1}^{m} y_r$ where $\{y_m\}_{r=1}^{m}$ are independent random variables. Previous argument mainly applies Markov inequality, which pays a factor of $1/\delta$ around the mean for error probability δ. But we can obtain much tighter concentration bound by taking advantage of independence as in Bernstein inequality and Hoeffding inequality. This allows us to improve the dependency on δ from $1/\delta$ to $\log 1/\delta$.

We also make use of matrix spectral norm to deal with summation of the form $\|\sum_{i=1}^{n} a_i x_i\|_2$ where $\{a_i\}_{i=1}^{n}$ are scalars and $\{x_i\}_{i=1}^{n}$ are vectors. Naively applying triangle inequality leads to an upper bound proportional to $\|a\|_1$, which can be as large as $\sqrt{n}\|a\|_2$. Instead, we observe that the matrix formed by $\begin{pmatrix} x_1 & \cdots & x_n \end{pmatrix} := X$ has good singular value property, which allows us to obtain the bound $\|X\|_2 \cdot \|a\|_2$. Therefore, this bound does not rely on number of inputs explicitly.

Roadmap We provide some basic definitions and probability tools in Section 28.2. We define the optimization problem in Section 28.3. We present our quartic result in Section 28.4. We improve it to cubic and quadratic in Section 28.5 and Section 28.6.

28.2 Preliminaries

28.2.1 Notation

We use $[n]$ to denote $\{1, 2, \cdots, n\}$. We use ϕ to denote ReLU activation function, i.e., $\phi(x) = \max\{x, 0\}$. For an event $f(x)$, we define $\mathbf{1}_{f(x)}$ such that $\mathbf{1}_{f(x)} = 1$ if $f(x)$ holds and $\mathbf{1}_{f(x)} = 0$ otherwise. For a matrix A, we use $\|A\|$ to denote the spectral norm of A. We define $\|A\|_F = (\sum_i \sum_j A_{i,j}^2)^{1/2}$ and $\|A\|_1 = \sum_i \sum_j |A_{i,j}|$.

28.3 Problem Formulation

Our problem formulation is the same as [DZPS19]. We consider a two-layer ReLU activated neural network with m neurons in the hidden layer:

$$f(W, x, a) = \frac{1}{\sqrt{m}} \sum_{r=1}^{m} a_r \phi(w_r^\top x),$$

where $x \in \mathbb{R}^d$ is the input, $w_1, \cdots, w_m \in \mathbb{R}^d$ are weight vectors in the first layer, $a_1, \cdots, a_m \in \mathbb{R}$ are weights in the second layer. For simplicity, we only optimize W but not optimize a and W at the same time.

Recall that the ReLU function $\phi(x) = \max\{x, 0\}$. Therefore for $r \in [m]$, we have

$$\frac{f(W, x, a)}{\partial w_r} = \frac{1}{\sqrt{m}} a_r x \mathbf{1}_{w_r^\top x \geq 0}. \tag{28.1}$$

We apply the gradient descent to optimize the weight matrix W in the following standard way,

$$W(k+1) = W(k) - \eta \frac{\partial L(W(k))}{\partial W(k)}. \tag{28.2}$$

We define objective function L as follows

$$L(W) = \frac{1}{2} \sum_{i=1}^{n} (y_i - f(W, x_i, a))^2.$$

We can compute the gradient of L in terms of w_r

$$\frac{\partial L(W)}{\partial w_r} = \frac{1}{\sqrt{m}} \sum_{i=1}^{n} (f(W, x_i, a_r) - y_i) a_r x_i \mathbf{1}_{w_r^\top x_i \geq 0}. \tag{28.3}$$

We consider the ordinary differential equation defined by

$$\frac{\mathrm{d} w_r(t)}{\mathrm{d} t} = -\frac{\partial L(W)}{\partial w_r}. \tag{28.4}$$

At time t, let $u(t) = (u_1(t), \cdots, u_n(t)) \in \mathbb{R}^n$ be the prediction vector where each $u_i(t)$ is defined as

$$u_i(t) = f(W(t), a, x_i). \tag{28.5}$$

28.4 Quartic Suffices

28.4.1 Bounding the difference between continuous and discrete

Lemma 28.4.1 (Lemma 3.1 in [DZPS19]). *We define $H^{\mathrm{cts}}, H^{\mathrm{dis}} \in \mathbb{R}^{n\times n}$ as follows*

$$H^{\mathrm{cts}}_{i,j} = \mathop{\mathbb{E}}_{w\sim\mathcal{N}(0,I)}\left[x_i^\top x_j \mathbf{1}_{w^\top x_i\geq 0, w^\top x_j\geq 0}\right],$$
$$H^{\mathrm{dis}}_{i,j} = \frac{1}{m}\sum_{r=1}^m \left[x_i^\top x_j \mathbf{1}_{w_r^\top x_i\geq 0, w_r^\top x_j\geq 0}\right].$$

Let $\lambda = \lambda_{\min}(H^{\mathrm{cts}})$. If $m = \Omega(\lambda^{-2}n^2\log(n/\delta))$, we have

$$\|H^{\mathrm{dis}} - H^{\mathrm{cts}}\|_F \leq \frac{\lambda}{4}, \text{ and } \lambda_{\min}(H^{\mathrm{dis}}) \geq \frac{3}{4}\lambda.$$

hold with probability at least $1-\delta$.

For the completeness, we still provide a proof here.

Proof. For every fixed pair (i,j), $H^{\mathrm{dis}}_{i,j}$ is an average of independent random variables, i.e.

$$H^{\mathrm{dis}}_{i,j} = \frac{1}{m}\sum_{r=1}^m x_i^\top x_j \mathbf{1}_{w_r^\top x_i\geq 0, w_r^\top x_j\geq 0}.$$

Then the expectation of $H^{\mathrm{dis}}_{i,j}$ is

$$\begin{aligned}\mathbb{E}[H^{\mathrm{dis}}_{i,j}] &= \frac{1}{m}\sum_{r=1}^m \mathop{\mathbb{E}}_{w_r\sim N(0,I_d)}\left[x_i^\top x_j \mathbf{1}_{w_r^\top x_i\geq 0, w_r^\top x_j\geq 0}\right] \\ &= \mathop{\mathbb{E}}_{w\sim N(0,I_d)}\left[x_i^\top x_j \mathbf{1}_{w^\top x_i\geq 0, w^\top x_j\geq 0}\right] \\ &= H^{\mathrm{cts}}_{i,j}.\end{aligned}$$

For $r\in[m]$, let $z_r = \frac{1}{m}x_i^\top x_j \mathbf{1}_{w_r^\top x_i\geq 0, w_r^\top x_j\geq 0}$. Then z_r is a random function of w_r, hence $\{z_r\}_{r\in[m]}$ are mutually independent. Moreover, $-\frac{1}{m}\leq z_r\leq \frac{1}{m}$. So by Hoeffding inequality(Lemma A.1.5) we have for all $t>0$,

$$\Pr\left[|H^{\mathrm{dis}}_{i,j} - H^{\mathrm{cts}}_{i,j}|\geq t\right] \leq 2\exp\left(-\frac{2t^2}{4/m}\right) = 2\exp(-mt^2/2)$$

Setting $t = (\frac{1}{m} 2 \log(2n^2/\delta))^{1/2}$, we can apply union bound on all pairs (i, j) to get with probability at least $1 - \delta$, for all $i, j \in [n]$,

$$|H^{\mathrm{dis}}_{i,j} - H^{\mathrm{cts}}_{i,j}| \leq \Big(\frac{2}{m} \log(2n^2/\delta)\Big)^{1/2} \leq 4\Big(\frac{\log(n/\delta)}{m}\Big)^{1/2}.$$

Thus we have

$$\|H^{\mathrm{dis}} - H^{\mathrm{cts}}\|^2 \leq \ \|H^{\mathrm{dis}} - H^{\mathrm{cts}}\|_F^2 = \ \sum_{i=1}^{n} \sum_{j=1}^{n} |H^{\mathrm{dis}}_{i,j} - H^{\mathrm{cts}}_{i,j}|^2 \leq \frac{1}{m} 16 n^2 \log(n/\delta).$$

Hence if $m = \Omega(\lambda^{-2} n^2 \log(n/\delta))$ we have the desired result. □

We define the event

$$A_{i,r} = \Big\{ \exists u : \|u - \widetilde{w}_r\|_2 \leq R, \mathbf{1}_{x_i^\top \widetilde{w}_r \geq 0} \neq \mathbf{1}_{x_i^\top u \geq 0} \Big\}.$$

Note this event happens if and only if $|\widetilde{w}_r^\top x_i| < R$. Recall that $\widetilde{w}_r \sim \mathcal{N}(0, I)$. By anti-concentration inequality of Gaussian (Lemma A.1.11), we have

$$\Pr[A_{i,r}] = \Pr_{z \sim \mathcal{N}(0,1)}[|z| < R] \leq \frac{2R}{\sqrt{2\pi}}. \tag{28.6}$$

28.4.2 Bounding changes of H when w is in a small ball

We improve the Lemma 3.2 in [DZPS19] from the two perspective : one is the probability, and the other is upper bound on spectral norm.

Lemma 28.4.2 (perturbed w)**.** *Let $R \in (0,1)$. If $\widetilde{w}_1, \cdots, \widetilde{w}_m$ are i.i.d. generated $\mathcal{N}(0, I)$. For any set of weight vectors $w_1, \cdots, w_m \in \mathbb{R}^d$ that satisfy for any $r \in [m]$, $\|\widetilde{w}_r - w_r\|_2 \leq R$, then the $H : \mathbb{R}^{m \times d} \to \mathbb{R}^{n \times n}$ defined*

$$H(w)_{i,j} = \frac{1}{m} x_i^\top x_j \sum_{r=1}^m \mathbf{1}_{w_r^\top x_i \geq 0, w_r^\top x_j \geq 0}.$$

Then we have

$$\|H(w) - H(\widetilde{w})\|_F < 2nR,$$

holds with probability at least $1 - n^2 \cdot \exp(-mR/10)$.

Proof. The random variable we care is

$$\begin{aligned}
\sum_{i=1}^n \sum_{j=1}^n |H(\widetilde{w})_{i,j} - H(w)_{i,j}|^2 = & \frac{1}{m^2} \sum_{i=1}^n \sum_{j=1}^n \left| x_i^\top x_j \sum_{r=1}^m (\mathbf{1}_{\widetilde{w}_r^\top x_i \geq 0, \widetilde{w}_r^\top x_j \geq 0} - \mathbf{1}_{w_r^\top x_i \geq 0, w_r^\top x_j \geq 0}) \right|^2 \\
\leq & \frac{1}{m^2} \sum_{i=1}^n \sum_{j=1}^n \left(\sum_{r=1}^m \mathbf{1}_{\widetilde{w}_r^\top x_i \geq 0, \widetilde{w}_r^\top x_j \geq 0} - \mathbf{1}_{w_r^\top x_i \geq 0, w_r^\top x_j \geq 0} \right)^2 \\
= & \frac{1}{m^2} \sum_{i=1}^n \sum_{j=1}^n \Big(\sum_{r=1}^m s_{r,i,j} \Big)^2,
\end{aligned}$$

where the last step follows from for each r, i, j, we define

$$s_{r,i,j} := \mathbf{1}_{\widetilde{w}_r^\top x_i \geq 0, \widetilde{w}_r^\top x_j \geq 0} - \mathbf{1}_{w_r^\top x_i \geq 0, w_r^\top x_j \geq 0}.$$

We consider i, j are fixed. We simplify $s_{r,i,j}$ to s_r.

Then s_r is a random variable that only depends on $\widetilde{w}_r$. Since $\{\widetilde{w}_r\}_{r=1}^m$ are independent, $\{s_r\}_{r=1}^m$ are also mutually independent.

If $\neg A_{i,r}$ and $\neg A_{j,r}$ happen, then

$$\left|\mathbf{1}_{\widetilde{w}_r^\top x_i \geq 0, \widetilde{w}_r^\top x_j \geq 0} - \mathbf{1}_{w_r^\top x_i \geq 0, w_r^\top x_j \geq 0}\right| = 0.$$

If $A_{i,r}$ or $A_{j,r}$ happen, then

$$\left|\mathbf{1}_{\widetilde{w}_r^\top x_i \geq 0, \widetilde{w}_r^\top x_j \geq 0} - \mathbf{1}_{w_r^\top x_i \geq 0, w_r^\top x_j \geq 0}\right| \leq 1.$$

So we have

$$\mathop{\mathbb{E}}_{\widetilde{w}_r}[s_r] \leq \mathop{\mathbb{E}}_{\widetilde{w}_r}\left[\mathbf{1}_{A_{i,r} \vee A_{j,r}}\right] \leq \Pr[A_{i,r}] + \Pr[A_{j,r}] \leq \frac{4R}{\sqrt{2\pi}} \leq 2R,$$

and

$$\mathop{\mathbb{E}}_{\widetilde{w}_r}\left[\left(s_r - \mathop{\mathbb{E}}_{\widetilde{w}_r}[s_r]\right)^2\right] = \mathop{\mathbb{E}}_{\widetilde{w}_r}[s_r^2] - \mathop{\mathbb{E}}_{\widetilde{w}_r}[s_r]^2 \leq \mathop{\mathbb{E}}_{\widetilde{w}_r}[s_r^2] \leq \mathop{\mathbb{E}}_{\widetilde{w}_r}\left[\left(\mathbf{1}_{A_{i,r} \vee A_{j,r}}\right)^2\right] \leq \frac{4R}{\sqrt{2\pi}} \leq 2R.$$

We also have $|s_r| \leq 1$. So we can apply Bernstein inequality (Lemma A.1.2) to get for all $t > 0$,

$$\begin{aligned}\Pr\left[\sum_{r=1}^m s_r \geq 2mR + mt\right] &\leq \Pr\left[\sum_{r=1}^m (s_r - \mathbb{E}[s_r]) \geq mt\right] \\ &\leq \exp\left(-\frac{m^2t^2/2}{2mR + mt/3}\right).\end{aligned}$$

Choosing $t = R$, we get

$$\Pr\left[\sum_{r=1}^m s_r \geq 3mR\right] \leq \exp\left(-\frac{m^2R^2/2}{2mR + mR/3}\right) \leq \exp\left(-mR/10\right).$$

Thus, we can have

$$\Pr\left[\frac{1}{m}\sum_{r=1}^m s_r \geq 2R\right] \leq \exp(-mR/10).$$

Therefore, we complete the proof. □

Table 28.2: Table of Parameters for the $m = \widetilde{\Omega}(n^4)$ result in Section 28.4. **Nt.** stands for notations.

28.4.3 Loss is decreasing while weights are not changing much

For simplicity of notation, we provide the following definition.

Definition 28.4.1. For any $s \in [0,t]$, we define matrix $H(s) \in \mathbb{R}^{n\times n}$ as follows

$$H(s)_{i,j} = \frac{1}{m}\sum_{r=1}^{m} x_i^\top x_j \mathbf{1}_{w_r(s)^\top x_i \geq 0, w_r(s)^\top x_j \geq 0}.$$

With H defined, it becomes more convenient to write the dynamics of predictions.

For each $i \in [n]$, we have

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}t} u_i(t) &= \sum_{r=1}^{m} \left\langle \frac{\partial f(W(t), a, x_i)}{\partial w_r(t)}, \frac{\mathrm{d} w_r(t)}{\mathrm{d}t} \right\rangle \\
&= \sum_{r=1}^{m} \left\langle \frac{\partial f(W(t), a, x_i)}{\partial w_r(t)}, -\frac{\partial L(w(t), a)}{\partial w_r(t)} \right\rangle \\
&= \sum_{r=1}^{m} \left\langle \frac{\partial f(W(t), a, x_i)}{\partial w_r(t)}, -\frac{1}{\sqrt{m}} \sum_{i=1}^{n} (f(W, x_i, a_r) - y_i) a_r x_i \mathbf{1}_{w_r^\top x_i \geq 0} \right\rangle \\
&= \sum_{j=1}^{n} (y_j - u_j(t)) \left\langle \frac{\partial f(W(t), a, x_i)}{\partial w_r(t)}, \frac{\partial f(W(t), a, x_j)}{\partial w_r(t)} \right\rangle \\
&= \sum_{j=1}^{n} (y_j - u_j(t)) H(t)_{i,j}
\end{aligned}$$

where the first step follows from (28.5) and the chain rule of derivatives, the second step uses (28.3), the third step uses (28.4), the fourth step uses (28.1) and (28.5), and the last step uses the definition of the matrix H.

Hence, we have the following compact expression for $\frac{\mathrm{d}}{\mathrm{d}t} u(t)$ as a whole vector:

$$\frac{\mathrm{d}}{\mathrm{d}t} u(t) = H(t) \cdot (y - u(t)).$$

Lemma 28.4.3 (Lemma 3.3 in [DZPS19])**.** *Suppose for $0 \leq s \leq t$, $\lambda_{\min}(H(w(s))) \geq \lambda/2$. Let D_{cts} be defined as*

$$D_{\mathrm{cts}} := \frac{\sqrt{n} \|y - u(0)\|_2}{\sqrt{m\lambda}}.$$

Then we have

$$\|y - u(t)\|_2^2 \leq \exp(-\lambda t) \cdot \|y - u(0)\|_2^2,$$

and

$$\|w_r(t) - w_r(0)\|_2 \leq D_{\mathrm{cts}}.$$

For the completeness, we still provide a proof.

Proof. Recall we can write the dynamics of predictions as

$$\frac{\mathrm{d}}{\mathrm{d}t}u(t) = H(t) \cdot (y - u(t)).$$

We can calculate the loss function dynamics

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\|y - u(t)\|_2^2 = & -2(y - u(t))^\top \cdot H(t) \cdot (y - u(t)) \\ \leq & -\lambda \|y - u(t)\|_2^2.\end{aligned}$$

Thus we have $\frac{\mathrm{d}}{\mathrm{d}t}(\exp(\lambda t)\|y - u(t)\|_2^2) \leq 0$ and $\exp(\lambda t)\|y - u(t)\|_2^2$ is a decreasing function with respect to t.

Using this fact we can bound the loss

$$\|y - u(t)\|_2^2 \leq \exp(-\lambda t)\|y - u(0)\|_2^2. \tag{28.7}$$

Now, we can bound the gradient norm. Recall for $0 \leq s \leq t$,

$$\begin{aligned}\left\|\frac{\mathrm{d}}{\mathrm{d}s}w_r(s)\right\|_2 = & \left\|\sum_{i=1}^n (y_i - u_i)\frac{1}{\sqrt{m}}a_r x_i \cdot \mathbf{1}_{w_r(s)^\top x_i \geq 0}\right\|_2 \\ \leq & \frac{1}{\sqrt{m}}\sum_{i=1}^n |y_i - u_i(s)| \\ \leq & \frac{\sqrt{n}}{\sqrt{m}}\|y - u(s)\|_2 \\ \leq & \frac{\sqrt{n}}{\sqrt{m}}\exp(-\lambda s)\|y - u(0)\|_2.\end{aligned} \tag{28.8}$$

where the first step follows from (28.3), the second step follows from triangle inequality and $a_r = \pm 1$ for $r \in [m]$ and $\|x_i\|_2 = 1$ for $i \in [n]$, the third step follows from Cauchy-Schwartz inequality, and the last step follows from (28.7).

Integrating the gradient, we can bound the distance from the initialization

$$\begin{aligned}\|w_r(t) - w_r(0)\|_2 &\le \int_0^t \left\| \frac{\mathrm{d}}{\mathrm{d}s} w_r(s) \right\|_2 \mathrm{d}s \\ &\le \frac{\sqrt{n}\|y - u(0)\|_2}{\sqrt{m}\lambda}.\end{aligned}$$

□

Lemma 28.4.4 (Lemma 3.4 in [DZPS19]). *If $D_{\mathrm{cts}} < R$. then for all $t \ge 0$, $\lambda_{\min}(H(t)) \ge \frac{1}{2}\lambda$. Moreover, for all $r \in [m]$,*

$$\|w_r(t) - w_r(0)\| \le D_{\mathrm{cts}},$$

and

$$\|y - u(t)\|_2^2 \le \exp(-\lambda t) \cdot \|y - u(0)\|_2^2.$$

For the completeness, we still provide a proof.

Proof. Assume the conclusion does not hold at time t. We argue there must be some $s \le t$ so that $\lambda_{\min}(H(s)) < \frac{1}{2}\lambda$.

If $\lambda_{\min}(H(t)) < \frac{1}{2}\lambda$, then we can simply take $s = t$.

Otherwise since the conclusion does not hold, there exists r so that

$$\|w_r(t) - w_r(0)\| \ge D_{\mathrm{cts}} \quad \text{or} \quad \|y - u(t)\|_2^2 > \exp(-\lambda t)\|y - u(0)\|_2^2.$$

Then by Lemma 28.4.3, there exists $s \le t$ such that

$$\lambda_{\min}(H(s)) < \frac{1}{2}\lambda.$$

By Lemma 28.4.2, there exists $t_0 > 0$ defined as

$$t_0 = \inf \left\{ t > 0 : \max_{r \in [m]} \|w_r(t) - w_r(0)\|_2^2 \geq R \right\}.$$

Thus at time t_0, there exists $r \in [m]$ satisfying $\|w_r(t_0) - w_r(0)\|_2^2 = R$.

By Lemma 28.4.2,

$$\lambda_{\min}(H(t')) \geq \frac{1}{2}\lambda, \forall t' \leq t_0.$$

However, by Lemma 28.4.3, this implies

$$\|w_r(t_0) - w_r(0)\|_2 \leq D_{\text{cts}} < R,$$

which is a contradiction. □

28.4.4 Convergence

Theorem 28.4.5. *Recall that* $\lambda = \lambda_{\min}(H^{\text{cts}}) > 0$. *Let* $m = \Omega(\lambda^{-4} n^4 \log(n/\delta))$, *we i.i.d. initialize* $w_r \in \mathcal{N}(0, I)$, a_r *sampled from* $\{-1, +1\}$ *uniformly at random for* $r \in [m]$, *and we set the step size* $\eta = O(\lambda/n^2)$ *then with probability at least* $1-\delta$ *over the random initialization we have for* $k = 0, 1, 2, \cdots$

$$\|u(k) - y\|_2^2 \leq (1 - \eta\lambda/2)^k \cdot \|u(0) - y\|_2^2. \tag{28.9}$$

Correctness We prove Theorem 28.4.5 by induction. The base case is $i = 0$ and it is trivially true. Assume for $i = 0, \cdots, k$ we have proved (28.9) to be true. We want to show (28.9) holds for $i = k + 1$.

From the induction hypothesis, we have the following Lemma stating that the weights should not change too much.

Lemma 28.4.6 (Corollary 4.1 in [DZPS19])**.** *If* (28.9) *holds for* $i = 0, \cdots, k$, *then we have for all* $r \in [m]$

$$\|w_r(k+1) - w_r(0)\|_2 \leq \frac{4\sqrt{n}\|y - u(0)\|_2}{\sqrt{m}\lambda} := D$$

For the completeness, we still provide the proof

Proof. We use the norm of gradient to bound this distance,

$$\begin{aligned}
\|w_r(k+1) - w_r(0)\|_2 &\leq \eta \sum_{i=0}^{k} \left\| \frac{\partial L(W(i))}{\partial w_r(i)} \right\|_2 \\
&\leq \eta \sum_{i=0}^{k} \frac{\sqrt{n}\|y - u(i)\|_2}{\sqrt{m}} \\
&\leq \eta \sum_{i=0}^{k} \frac{\sqrt{n}(1-\eta\lambda/2)^{i/2}}{\sqrt{m}} \|y - u(0)\|_2 \\
&\leq \eta \sum_{i=0}^{\infty} \frac{\sqrt{n}(1-\eta\lambda/2)^{i/2}}{\sqrt{m}} \|y - u(0)\|_2 \\
&= \frac{4\sqrt{n}\|y - u(0)\|_2}{\sqrt{m}\lambda},
\end{aligned}$$

where the first step follows from (28.2), the second step follows from (28.8), the third step follows from the induction hypothesis, the fourth step relaxes the summation to an infinite summation, and the last step follows from $\sum_{i=0}^{\infty}(1-\eta\lambda/2)^{i/2} = \frac{2}{\eta\lambda}$.

Thus, we complete the proof. □

Next, we calculate the different of predictions between two consecutive iterations, analogue to $\frac{\mathrm{d}u_i(t)}{\mathrm{d}t}$ term in Lemma 28.4.3. For each $i \in [n]$, we have

$$\begin{aligned}
u_i(k+1) - u_i(k) &= \frac{1}{\sqrt{m}} \sum_{r=1}^{m} a_r \cdot \big(\phi(w_r(k+1)^\top x_i) - \phi(w_r(k)^\top x_i)\big) \\
&= \frac{1}{\sqrt{m}} \sum_{r=1}^{m} a_r \cdot \left(\phi\left(\left(w_r(k) - \eta \frac{\partial L(W(k))}{\partial w_r(k)} \right)^\top x_i \right) - \phi(w_r(k)^\top x_i) \right).
\end{aligned}$$

Here we divide the right hand side into two parts. $v_{1,i}$ represents the terms that the pattern does not change and $v_{2,i}$ represents the term that pattern may changes. For each

$i \in [n]$, we define $v_{1,i}$ and $v_{2,i}$ as follows

$$v_{1,i} := \frac{1}{\sqrt{m}} \sum_{r \in S_i} a_r \cdot \left(\phi \left(\left(w_r(k) - \eta \frac{\partial L(W(k))}{\partial w_r(k)} \right)^\top x_i \right) - \phi(w_r(k)^\top x_i) \right),$$
$$v_{2,i} := \frac{1}{\sqrt{m}} \sum_{r \in \overline{S}_i} a_r \cdot \left(\phi \left(\left(w_r(k) - \eta \frac{\partial L(W(k))}{\partial w_r(k)} \right)^\top x_i \right) - \phi(w_r(k)^\top x_i) \right).$$

Thus, we can rewrite $u(k+1) - u(k) \in \mathbb{R}^n$ in the following sense

$$u(k+1) - u(k) = v_1 + v_2.$$

In order to analyze $v_1 \in \mathbb{R}^n$, we provide definition of H and $H^\perp \in \mathbb{R}^{n \times n}$ first,

$$H(k)_{i,j} = \frac{1}{m} \sum_{r=1}^m x_i^\top x_j \mathbf{1}_{w_r(k)^\top x_i \geq 0, w_r(k)^\top x_j \geq 0},$$
$$H(k)^\perp_{i,j} = \frac{1}{m} \sum_{r \in \overline{S}_i} x_i^\top x_j \mathbf{1}_{w_r(k)^\top x_i \geq 0, w_r(k)^\top x_j \geq 0}.$$

Then, we can rewrite $v_{1,i} \in \mathbb{R}$

$$\begin{aligned} v_{1,i} = & -\frac{\eta}{m} \sum_{j=1}^n x_i^\top x_j (u_j - y_j) \sum_{r \in S_i} \mathbf{1}_{w_r(k)^\top x_i \geq 0, w_r(k)^\top x_j \geq 0} \\ = & -\eta \sum_{j=1}^n (u_j - y_j)(H_{i,j}(k) - H^\perp_{i,j}(k)), \end{aligned}$$

which means vector $v_1 \in \mathbb{R}^n$ can be written as

$$v_1 = \eta (y - u(k))^\top (H(k) - H^\perp(k)). \tag{28.10}$$

We are ready to prove the induction hypothesis. We can rewrite $\|y - u(k+1)\|_2^2$ as follows:

$$\begin{aligned} \|y - u(k+1)\|_2^2 = & \|y - u(k) - (u(k+1) - u(k))\|_2^2 \\ = & \|y - u(k)\|_2^2 - 2(y - u(k))^\top (u(k+1) - u(k)) + \|u(k+1) - u(k)\|_2^2. \end{aligned}$$

We can rewrite the second term in the above Equation in the following sense,

$$\begin{aligned}
&(y-u(k))^\top (u(k+1)-u(k)) \\
=\ &(y-u(k))^\top (v_1+v_2) \\
=\ &(y-u(k))^\top v_1 + (y-u(k))^\top v_2 \\
=\ &\eta (y-u(k))^\top H(k)(y-u(k)) - \eta (y-u(k))^\top H(k)^\perp (y-u(k)) + (y-u(k))^\top v_2,
\end{aligned}$$

where the third step follows from Eq. (28.10).

We define

$$\begin{aligned}
C_1 =\ & -2\eta (y-u(k))^\top H(k)(y-u(k)), \\
C_2 =\ & 2\eta (y-u(k))^\top H(k)^\perp (y-u(k)), \\
C_3 =\ & -2(y-u(k))^\top v_2, \\
C_4 =\ & \|u(k+1)-u(k)\|_2^2.
\end{aligned}$$

Thus, we have

$$\begin{aligned}
\|y-u(k+1)\|_2^2 &= \|y-u(k)\|_2^2 + C_1 + C_2 + C_3 + C_4 \\
&\leq \|y-u(k)\|_2^2 (1 - \eta\lambda + 8\eta n R + 8\eta n R + \eta^2 n^2),
\end{aligned}$$

where the last step follows from Claim 28.4.8, 28.4.9, 28.4.10 and 28.4.11, which we will prove given later.

Choice of η and R. Next, we want to choose η and R such that

$$(1 - \eta\lambda + 8\eta n R + 8\eta n R + \eta^2 n^2) \leq (1 - \eta\lambda/2). \tag{28.11}$$

If we set $\eta = \frac{\lambda}{4n^2}$ and $R = \frac{\lambda}{64n}$, we have

$$8\eta n R + 8\eta n R = 16\eta n R \leq \eta\lambda/4, \quad \text{and} \quad \eta^2 n^2 \leq \eta\lambda/4.$$

This implies

$$\|y - u(k+1)\|_2^2 \leq \|y - u(k)\|_2^2 \cdot (1 - \eta\lambda/2)$$

holds with probability at least $1 - 2n\exp(-mR)$.

Over-parameterization size, lower bound on m. We require

$$D = \frac{4\sqrt{n}\|y - u(0)\|_2}{\sqrt{m}\lambda} < R = \frac{\lambda}{64n},$$

and

$$2n\exp(-mR) \leq \delta.$$

By Claim 28.4.7, it is sufficient to choose $m = \Omega(\lambda^{-4} n^4 \log(m/\delta)\log^2(n/\delta))$.

28.4.5 Technical claims

Claim 28.4.7. *For $0 < \delta < 1$, with probability at least $1 - \delta$,*

$$\|y - u(0)\|_2^2 = O(n \log(m/\delta) \log^2(n/\delta)).$$

Proof.

$$\begin{aligned}
\|y - u(0)\|_2^2 = & \sum_{i=1}^n (y_i - f(W(0), a, x_i))^2 \\
= & \sum_{i=1}^n \Big(y_i - \frac{1}{\sqrt{m}} \sum_{r=1}^m a_r \phi(w_r^\top x_i) \Big)^2 \\
= & \sum_{i=1}^n y_i^2 - 2 \sum_{i=1}^n \frac{y_i}{\sqrt{m}} \sum_{r=1}^m a_r \phi(w_r^\top x_i) + \sum_{i=1}^n \frac{1}{m} \Big(\sum_{r=1}^m a_r \phi(w_r^\top x_i) \Big)^2.
\end{aligned}$$

Fix $r \in [m]$ and $i \in [n]$. Since $w_r \sim N(0, I)$ and $\|x_i\|_2 = 1$, $w_r^\top x_i$ follows distribution $N(0, 1)$. From concentration of Gaussian distribution, we have

$$\Pr_{w_r}[w_r^\top x_i \geq \sqrt{2 \log(2mn/\delta)}] \leq \frac{\delta}{2mn}.$$

Let E_1 be the even that for all $r \in [m]$ and $i \in [n]$ we have

$$\phi(w_r^\top x_i) \leq \sqrt{2 \log(2mn/\delta)}.$$

Then by union bound, $\Pr[E_1] \geq 1 - \frac{\delta}{2}$,

Fix $i \in [n]$. For every $r \in [m]$, we define random variable $z_{i,r}$ as

$$z_{i,r} := \frac{1}{\sqrt{m}} \cdot a_r \cdot \phi(w_r^\top x_i) \cdot \mathbf{1}_{w_r^\top x_i \leq \sqrt{2 \log(2mn/\delta)}}.$$

Then $z_{i,r}$ only depends on $a_r \in \{-1,1\}$ and $w_r \sim N(0,I)$. Notice that $\mathbb{E}_{a_r,w_r}[z_{i,r}] = 0$, and $|z_{i,r}| \leq \sqrt{2\log(2mn/\delta)}$. Moreover,

$$\begin{aligned}
\mathop{\mathbb{E}}_{a_r,w_r}[z_{i,r}^2] &= \mathop{\mathbb{E}}_{a_r,w_r}\left[\frac{1}{m}a_r^2\phi^2(w_r^\top x_i)\mathbf{1}^2_{w_r^\top x_i \leq \sqrt{2\log(2mn/\delta)}}\right] \\
&= \frac{1}{m}\mathop{\mathbb{E}}_{a_r}[a_r^2]\cdot \mathop{\mathbb{E}}_{w_r}\left[\phi^2(w_r^\top x_i)\mathbf{1}^2_{w_r^\top x_i \leq \sqrt{2\log(2mn/\delta)}}\right] \\
&\leq \frac{1}{m}\cdot 1 \cdot \mathop{\mathbb{E}}_{w_r}[(w_r^\top x_i)^2] \\
&= \frac{1}{m},
\end{aligned}$$

where the second step uses independence between a_r and w_r, the third step uses $a_r \in \{-1,1\}$ and $\phi(t) = \max\{t,0\}$, and the last step follows from $w_r^\top x_i \sim N(0,1)$.

Now we are ready to apply Bernstein inequality (Lemma A.1.2) to get for all $t > 0$,

$$\Pr\left[\sum_{r=1}^m z_{i,r} > t\right] \leq \exp\left(-\frac{t^2/2}{m\cdot\frac{1}{m} + \sqrt{2\log(2mn/\delta)}\cdot t/3}\right).$$

Setting $t = \sqrt{2\log(2mn/\delta)}\cdot\log(4n/\delta)$, we have with probability at least $1 - \frac{\delta}{4n}$,

$$\sum_{r=1}^m z_{i,r} \leq \sqrt{2\log(2mn/\delta)}\cdot\log(4n/\delta).$$

Notice that we can also apply Bernstein inequality (Lemma A.1.2) on $-z_{i,r}$ to get

$$\Pr\left[\sum_{r=1}^m z_{i,r} < -t\right] \leq \exp\left(-\frac{t^2/2}{m\cdot\frac{1}{m} + \sqrt{2\log(2mn/\delta)}\cdot t/3}\right).$$

Let E_2 be the event that for all $i \in [n]$,

$$\left|\sum_{r=1}^m z_{i,r}\right| \leq \sqrt{2\log(2mn/\delta)}\cdot\log(4n/\delta).$$

By applying union bound on all $i \in [n]$, we have $\Pr[E_2] \geq 1 - \frac{\delta}{2}$.

If both E_1 and E_2 happen, we have

$$\begin{aligned}
\|y - u(0)\|_2^2 &= \sum_{i=1}^n y_i^2 - 2\sum_{i=1}^n \frac{y_i}{\sqrt{m}} \sum_{r=1}^m a_r \phi(w_r^\top x_i) + \sum_{i=1}^n \frac{1}{m} \Big(\sum_{r=1}^m a_r \phi(w_r^\top x_i) \Big)^2 \\
&= \sum_{i=1}^n y_i^2 - 2\sum_{i=1}^n y_i \sum_{r=1}^m z_{i,r} + \sum_{i=1}^n \Big(\sum_{r=1}^m z_{i,r} \Big)^2 \\
&\leq \sum_{i=1}^n y_i^2 + 2\sum_{i=1}^n |y_i| \sqrt{2\log(2mn/\delta)} \cdot \log(4n/\delta) + \sum_{i=1}^n \Big(\sqrt{2\log(2mn/\delta)} \cdot \log(4n/\delta) \Big)^2 \\
&= O(n \log(m/\delta) \log^2(n/\delta)),
\end{aligned}$$

where the second step uses E_1, the third step uses E_2, and the last step follows from $|y_i| = O(1), \forall i \in [n]$.

By union bound, this will happen with probability at least $1 - \delta$. □

Claim 28.4.8. *Let $C_1 = -2\eta(y - u(k))^\top H(k)(y - u(k))$. We have*

$$C_1 \leq -\|y - u(k)\|_2^2 \cdot \eta\lambda.$$

Proof. By Lemma 28.4.2 and our choice of $R < \frac{\lambda}{8n}$, We have $\|H(0) - H(k)\|_F \leq 2n \cdot \frac{\lambda}{8n} = \frac{\lambda}{4}$. Recall that $\lambda = \lambda_{\min}(H(0))$. Therefore

$$\lambda_{\min}(H(k)) \geq \lambda_{\min}(H(0)) - \|H(0) - H(k)\| \geq \lambda/2.$$

Then we have

$$(y - u(k))^\top H(k)(y - u(k)) \geq \|y - u(k)\|_2^2 \cdot \lambda/2.$$

Thus, we complete the proof. □

Claim 28.4.9. *Let* $C_2 = 2\eta(y - u(k))^\top H(k)^\perp (y - u(k))$. *We have*

$$C_2 \leq \|y - u(k)\|_2^2 \cdot 8\eta n R.$$

holds with probability $1 - n\exp(-mR)$.

Proof. Note that

$$C_2 \leq 2\eta \|y - u(k)\|_2^2 \|H(k)^\perp\|.$$

It suffices to upper bound $\|H(k)^\perp\|$. Since $\|\cdot\| \leq \|\cdot\|_F$, then it suffices to upper bound $\|\cdot\|_F$.

For each $i \in [n]$, we define y_i as follows

$$y_i = \sum_{r=1}^{m} \mathbf{1}_{r \in \overline{S}_i}.$$

Then we have

$$\begin{aligned}
\|H(k)^{\perp}\|_F^2 &= \sum_{i=1}^{n}\sum_{j=1}^{n}(H(k)_{i,j}^{\perp})^2 \\
&= \sum_{i=1}^{n}\sum_{j=1}^{n}\Big(\frac{1}{m}\sum_{r\in\overline{S}_i} x_i^\top x_j \mathbf{1}_{w_r(k)^\top x_i\geq 0, w_r(k)^\top x_j\geq 0}\Big)^2 \\
&= \sum_{i=1}^{n}\sum_{j=1}^{n}\Big(\frac{1}{m}\sum_{r=1}^{m} x_i^\top x_j \mathbf{1}_{w_r(k)^\top x_i\geq 0, w_r(k)^\top x_j\geq 0}\cdot \mathbf{1}_{r\in\overline{S}_i}\Big)^2 \\
&= \sum_{i=1}^{n}\sum_{j=1}^{n}(\frac{x_i^\top x_j}{m})^2\Big(\sum_{r=1}^{m} \mathbf{1}_{w_r(k)^\top x_i\geq 0, w_r(k)^\top x_j\geq 0}\cdot \mathbf{1}_{r\in\overline{S}_i}\Big)^2 \\
&\leq \frac{1}{m^2}\sum_{i=1}^{n}\sum_{j=1}^{n}\Big(\sum_{r=1}^{m} \mathbf{1}_{w_r(k)^\top x_i\geq 0, w_r(k)^\top x_j\geq 0}\cdot \mathbf{1}_{r\in\overline{S}_i}\Big)^2 \\
&= \frac{n}{m^2}\sum_{i=1}^{n}\Big(\sum_{r=1}^{m} \mathbf{1}_{r\in\overline{S}_i}\Big)^2 \\
&= \frac{n}{m^2}\sum_{i=1}^{n} y_i^2.
\end{aligned}$$

Fix $i \in [n]$. The plan is to use Bernstein inequality to upper bound y_i with high probability.

First by Eq. (28.6) we have

$$\mathbb{E}[\mathbf{1}_{r\in\overline{S}_i}] \leq R.$$

We also have

$$\begin{aligned}
\mathbb{E}\left[(\mathbf{1}_{r\in\overline{S}_i} - \mathbb{E}[\mathbf{1}_{r\in\overline{S}_i}])^2\right] &= \mathbb{E}[\mathbf{1}_{r\in\overline{S}_i}^2] - \mathbb{E}[\mathbf{1}_{r\in\overline{S}_i}]^2 \\
&\leq \mathbb{E}[\mathbf{1}_{r\in\overline{S}_i}^2] \\
&\leq R.
\end{aligned}$$

Finally we have $|\mathbf{1}_{r\in\overline{S}_i} - \mathbb{E}[\mathbf{1}_{r\in\overline{S}_i}]| \leq 1$.

Notice that $\{\mathbf{1}_{r\in\overline{S}_i}\}_{r=1}^m$ are mutually independent, since $\mathbf{1}_{r\in\overline{S}_i}$ only depends on $w_r(0)$. Hence from Bernstein inequality (Lemma A.1.2) we have for all $t > 0$,

$$\Pr[y_i > m \cdot R + t] \leq \exp\left(-\frac{t^2/2}{m \cdot R + t/3}\right).$$

By setting $t = 3mR$, we have

$$\Pr[y_i > 4mR] \leq \exp(-mR).$$

Hence by union bound, with probability at least $1 - n\exp(-mR)$,

$$\|H(k)^\perp\|_F^2 \leq \frac{n}{m^2} \cdot n \cdot (4mR)^2 = 16n^2R^2.$$

Putting all together we have

$$\|H(k)^\perp\| \leq \|H(k)^\perp\|_F \leq 4nR$$

with probability at least $1 - n\exp(-mR)$.

□

Claim 28.4.10. *Let $C_3 = -2(y - u(k))^\top v_2$. Then we have*

$$C_3 \leq \|y - u(k)\|_2^2 \cdot 8\eta nR.$$

with probability at least $1 - n\exp(-mR)$.

Proof. We have

$$\text{LHS} \leq 2\|y - u(k)\|_2 \cdot \|v_2\|_2.$$

We can upper bound $\|v_2\|_2$ in the following sense

$$\begin{aligned}
\|v_2\|_2^2 &\leq \sum_{i=1}^n \left(\frac{\eta}{\sqrt{m}} \sum_{r \in \overline{S}_i} \left| (\frac{\partial L(W(k))}{\partial w_r(k)})^\top x_i \right| \right)^2 \\
&= \frac{\eta^2}{m} \sum_{i=1}^n \left(\sum_{r=1}^m \mathbf{1}_{r \in \overline{S}_i} \left| (\frac{\partial L(W(k))}{\partial w_r(k)})^\top x_i \right| \right)^2 \\
&\leq \frac{\eta^2}{m} \cdot \max_{r \in [m]} \left| \frac{\partial L(W(k))}{\partial w_r(k)} \right|^2 \cdot \sum_{i=1}^n \left(\sum_{r=1}^m \mathbf{1}_{r \in \overline{S}_i} \right)^2 \\
&\leq \frac{\eta^2}{m} \cdot (\frac{\sqrt{n}}{\sqrt{m}} \|u(k) - y\|_2)^2 \cdot \sum_{i=1}^n \left(\sum_{r=1}^m \mathbf{1}_{r \in \overline{S}_i} \right)^2 \\
&\leq \frac{\eta^2}{m} \cdot (\frac{\sqrt{n}}{\sqrt{m}} \|u(k) - y\|_2)^2 \cdot \sum_{i=1}^n (4mR)^2 \\
&= 16 n^2 R^2 \eta^2 \|u(k) - y\|_2^2,
\end{aligned}$$

where the first step follows from definition of v_2, the fourth step follows from $\max_{r \in [m]} |\frac{\partial L(W(k))}{\partial w_r(k)}| \leq \frac{\sqrt{n}}{\sqrt{m}} \cdot \|u(k) - y\|_2$, the fifth step follows from $\sum_{r=1}^m \mathbf{1}_{r \in \overline{S}_i} \leq 4mR$ with probability at least $1 - \exp(-mR)$. □

Claim 28.4.11. *Let $C_4 = \|u(k+1) - u(k)\|_2^2$. Then we have*

$$C_4 \leq \eta^2 n^2 \|y - u(k)\|_2^2.$$

Proof. We have

$$\begin{aligned}
\text{LHS} &\leq \eta^2 \sum_{i=1}^n \frac{1}{m} \left(\sum_{r=1}^m \left\| \frac{\partial L(W(k))}{\partial w_r(k)} \right\|_2 \right)^2 \\
&\leq \eta^2 n^2 \|y - u(k)\|_2^2.
\end{aligned}$$

□

28.5 Cubic Suffices

We prove a more general version of Lemma 28.4.1 in this section.

Theorem 28.5.1 (Data-dependent version, bounding the difference between discrete and continuous)**.** *Let H^{cts} and H^{dis} be defined as Definition 28.1.1. Let λ, α, β be satisfied Assumption 28.1.1. If*

$$m = \Omega((\lambda^{-2}\beta + \lambda^{-1}\alpha)\log(n/\delta)),$$

we have

$$\|H^{\mathrm{dis}} - H^{\mathrm{cts}}\|_2 \leq \lambda/4, \text{ and } \lambda_{\min}(H^{\mathrm{dis}}) \geq \frac{3}{4}\lambda$$

holds with probability at least $1 - \exp(-\Omega(\log(n/\delta)))$.

Proof. Recall the definition, we know

$$H^{\mathrm{cts}} = \mathop{\mathbb{E}}_{w}[H(w)], \quad \text{and} \quad H^{\mathrm{dis}} = \frac{1}{m}\sum_{r=1}^{m} H(w_r).$$

We define matrix $Y_r = H(w_r) - \mathbb{E}_w[H(w)]$. We know that, Y_r are all independent,

$$\mathbb{E}[Y_r] = 0, \quad \|Y_r\| \leq \alpha, \quad \Big\| \sum_{r=1}^{m} \mathbb{E}[Y_r Y_r^\top] \Big\| \leq m\beta.$$

Let $Y = \sum_{r=1}^{m} Y_r$. We apply Matrix Bernstein inequality (Lemma A.2.2) with $t = \sqrt{m\beta\log(n/\delta)} + \alpha\log(n/\delta)$,

$$\begin{aligned}
\Pr[\|Y\| \geq t] &\leq 2n\exp\Big(-\frac{t^2/2}{m\beta + \alpha t/3}\Big) \\
&\leq 2n\exp(-\log(n/\delta)) \\
&\leq \exp(-\Omega(\log(n/\delta))).
\end{aligned}$$

Thus, we have

$$\Pr\left[\left\|\frac{1}{m}\sum_{r=1}^{m} Y_r\right\| \geq \frac{1}{m}(\sqrt{m\beta\log(n/\delta)} + \alpha\log(n/\delta))\right] \leq \exp(-\Omega(\log(n/\delta))).$$

In order to guarantee that $\frac{1}{m}(\sqrt{m\beta\log(n/\delta)} + \alpha\log(n/\delta)) \leq \lambda$, we need

$$\sqrt{m} \geq \lambda^{-1}\sqrt{\beta\log(n/\delta)}$$

when the first term is the dominated one; we need

$$m \geq \lambda^{-1}\alpha\log(n/\delta).$$

Overall, we need

$$m \geq \Omega((\lambda^{-2}\beta + \lambda^{-1}\alpha)\log(n/\delta)).$$

Thus, we complete the proof. □

Lemma 28.5.2 (Stronger version of Lemma 3.3 in [DZPS19])**.** *Let Part 4 in Assumption 28.1.1 hold. Let* $D_{\mathrm{cts}} = \frac{\sqrt{\alpha}\|y-u(0)\|_2}{\sqrt{m\lambda}}$*. Suppose for* $0 \leq s \leq t$*,* $\lambda_{\min}(H(s)) \geq \lambda/2$*. Then we have*

$$\|y - u(t)\|_2^2 \leq \exp(-\lambda t)\cdot\|y - u(0)\|_2^2,$$

and

$$\|w_r(t) - w_r(0)\|_2 \leq D_{\mathrm{cts}}.$$

Proof. Recall we can write the dynamics of predictions as

$$\frac{\mathrm{d}}{\mathrm{d}t}u(t) = H(t)\cdot(y - u(t)).$$

Table 28.3: Table of Parameters for the $m = \widetilde{\Omega}(n^3)$ result in Section 28.5. **Nt.** stands for notations.

Nt.	**Choice**	**Place**	**Comment**
λ	$:= \lambda_{\min}(H^{\mathrm{cts}})$	Part 1 of Ass. 28.1.1	Data-dependent
α	Absolute	Part 2 of Ass. 28.1.1	Data-dependent
β	Variance	Part 3 of Ass. 28.1.1	Data-dependent
R	λ/n	Eq. (28.11)	Maximal allowed movement of weight
D_{cts}	$\frac{\sqrt{\alpha}\\|y-u(0)\\|_2}{\sqrt{m}\lambda}$	Lemma 28.5.2	Actual moving distance, continuous case
D	$\frac{4\sqrt{\alpha}\\|y-u(0)\\|_2}{\sqrt{m}\lambda}$	Theorem 28.5.5	Actual moving distance, discrete case
η	$\lambda/(\alpha n)$	Eq. (28.11)	Step size of gradient descent
m	$(\lambda^{-2}\beta + \lambda^{-1}\alpha)\log(n/\delta)$	Theorem 28.5.1	Bounding discrete and continuous
m	$\lambda^{-4}\alpha n^3 \log^3(n/\delta)$	Lemma 28.4.4 Claim 28.4.7	$D < R$ and $\\|y - u(0)\\|_2^2 = \widetilde{O}(n)$

We can calculate the loss function dynamics

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}t}\|y-u(t)\|_2^2 = & -2(y-u(t))^\top \cdot H(t) \cdot (y-u(t)) \\ \leq & -\lambda \|y-u(t)\|_2^2. \end{aligned}$$

Thus we have $\frac{\mathrm{d}}{\mathrm{d}t}(\exp(\lambda t)\|y-u(t)\|_2^2) \leq 0$ and $\exp(\lambda t)\|y-u(t)\|_2^2$ is a decreasing function with respect to t.

Using this fact we can bound the loss

$$\|y-u(t)\|_2^2 \leq \exp(-\lambda t)\|y-u(0)\|_2^2.$$

Therefore, $u(t) \to y$ exponentially fast.

Now, we can bound the gradient norm. Recall for $0 \leq s \leq t$,

$$\left\| \frac{\mathrm{d}}{\mathrm{d}s} w_r(s) \right\|_2 = \left\| \sum_{i=1}^n (y_i - u_i) \frac{1}{\sqrt{m}} a_r x_i \cdot \mathbf{1}_{w_r(s)^\top x_i \geq 0} \right\|_2.$$

Define matrix $X_r \in \mathbb{R}^{d\times n}$ by setting the i-th column to be $\mathbf{1}_{w_r(s)^\top x_i \geq 0} \cdot x_i$, then $X_r^\top X_r = H(w_r(s))$, where $H(\cdot)$ is the matrix defined in Definition 28.1.1. Then we have $\|X_r^\top X_r\|_2 \leq \alpha$ by Part 4 in Assumption 28.1.1, which leads to $\|X_r\|_2 \leq \sqrt{\alpha}$. So we have

$$\begin{aligned}
\left\| \frac{\mathrm{d}}{\mathrm{d}s} w_r(s) \right\|_2 &= \frac{1}{\sqrt{m}} \|X_r(y - u(s))\|_2 \\
&\leq \frac{1}{\sqrt{m}} \|X_r\|_2 \|(y - u(s))\|_2 \\
&\leq \frac{\sqrt{\alpha}}{\sqrt{m}} \|y - u(s)\|_2 \\
&\leq \frac{\sqrt{\alpha}}{\sqrt{m}} \exp(-\lambda s) \|y - u(0)\|_2.
\end{aligned} \tag{28.12}$$

Integrating the gradient, we can bound the distance from the initialization

$$\begin{aligned}
\|w_r(t) - w_r(0)\|_2 \leq & \int_0^t \left\| \frac{\mathrm{d}}{\mathrm{d}s} w_r(s) \right\|_2 \mathrm{d}s \\
\leq & \frac{\sqrt{\alpha} \|y - u(0)\|_2}{\sqrt{m}\lambda}.
\end{aligned}$$

□

28.5.1 Technical claims

Claim 28.5.3. *Let* $C_3 = -2(y - u(k))^\top v_2$. *Then we have*

$$C_3 \le \|y - u(k)\|_2^2 \cdot 8\eta(\alpha n)^{1/2} R.$$

with probability at least $1 - n\exp(-mR)$.

Proof. We have

$$\text{LHS} \le 2\|y - u(k)\|_2 \cdot \|v_2\|_2.$$

We can upper bound $\|v_2\|_2$ in the following sense

$$\begin{aligned}
\|v_2\|_2^2 &\le \sum_{i=1}^n \left(\frac{\eta}{\sqrt{m}} \sum_{r \in \overline{S}_i} \left| \Big(\frac{\partial L(W(k))}{\partial w_r(k)} \Big)^\top x_i \right| \right)^2 \\
&= \frac{\eta^2}{m} \sum_{i=1}^n \left(\sum_{r=1}^m \mathbf{1}_{r \in \overline{S}_i} \left| \Big(\frac{\partial L(W(k))}{\partial w_r(k)} \Big)^\top x_i \right| \right)^2 \\
&\le \frac{\eta^2}{m} \cdot \max_{r \in [m]} \left| \frac{\partial L(W(k))}{\partial w_r(k)} \right|^2 \cdot \sum_{i=1}^n \left(\sum_{r=1}^m \mathbf{1}_{r \in \overline{S}_i} \right)^2 \\
&\le \frac{\eta^2}{m} \cdot \Big(\frac{\sqrt{\alpha}}{\sqrt{m}} \|u(k) - y\|_2 \Big)^2 \cdot \sum_{i=1}^n \left(\sum_{r=1}^m \mathbf{1}_{r \in \overline{S}_i} \right)^2 \\
&\le \frac{\eta^2}{m} \cdot \Big(\frac{\sqrt{\alpha}}{\sqrt{m}} \|u(k) - y\|_2 \Big)^2 \cdot \sum_{i=1}^n (4mR)^2 \\
&= 16\alpha n R^2 \eta^2 \|u(k) - y\|_2^2,
\end{aligned}$$

where the first step follows from definition of v_2, the fourth step follows from (28.12) and

$$\begin{aligned}
\max_{r \in [m]} \left| \frac{\partial L(W(k))}{\partial w_r(k)} \right| &= \max_{r \in [m]} \left| \frac{\mathrm{d} w_r(k)}{\mathrm{d} k} \right| \\
&\le \frac{\sqrt{\alpha}}{\sqrt{m}} \|y - u(k)\|_2,
\end{aligned}$$

the fifth step follows from $\sum_{r=1}^{m} \mathbf{1}_{r \in \overline{S}_i} \leq 4mR$ with probability at least $1 - \exp(-mR)$. $\square$

Claim 28.5.4. *Let $C_4 = \|u(k+1) - u(k)\|_2^2$. Then we have*

$$C_4 \leq \eta^2 \alpha n \|y - u(k)\|_2^2.$$

Proof. We have

$$\begin{aligned}
\text{LHS} &\leq \eta^2 \sum_{i=1}^{n} \frac{1}{m} \left(\sum_{r=1}^{m} \left\| \frac{\partial L(W(k))}{\partial w_r(k)} \right\|_2 \right)^2 \\
&\leq \eta^2 \sum_{i=1}^{n} \frac{1}{m} \left(\sum_{r=1}^{m} \frac{\sqrt{\alpha}}{\sqrt{m}} \|u(k) - y\|_2 \right)^2 \\
&\leq \eta^2 \alpha n \|y - u(k)\|_2^2.
\end{aligned}$$

$\square$

28.5.2 Main result

Theorem 28.5.5. *Recall that $\lambda = \lambda_{\min}(H^{\text{cts}}) > 0$. Let $m = \Omega(\lambda^{-4} n^3 \alpha \log^3(n/\delta))$, we i.i.d. initialize $w_r \in \mathcal{N}(0, I)$, a_r sampled from $\{-1, +1\}$ uniformly at random for $r \in [m]$, and we set the step size $\eta = O(\lambda/(\alpha n))$ then with probability at least $1 - \delta$ over the random initialization we have for $k = 0, 1, 2, \cdots$*

$$\|u(k) - y\|_2^2 \leq (1 - \eta\lambda/2)^k \cdot \|u(0) - y\|_2^2. \tag{28.13}$$

Proof. This proof, similar to the proof of Theorem 28.4.5, is again by induction. (28.13) trivially holds when $k = 0$, which is the base case.

If (28.13) holds for $k' = 0, \cdots, k$, then we claim that for all $r \in [m]$

$$\|w_r(k+1) - w_r(0)\|_2 \leq \frac{4\sqrt{\alpha}\|y - u(0)\|_2}{\sqrt{m}\lambda} := D \tag{28.14}$$

To see this, we use the norm of gradient to bound this distance,

$$\begin{aligned}
\|w_r(k+1) - w_r(0)\|_2 &\leq \eta \sum_{k'=0}^{k} \left\| \frac{\partial L(W(k'))}{\partial w_r(k')} \right\|_2 \\
&\leq \eta \sum_{k'=0}^{k} \frac{\sqrt{\alpha}\|y - u(k')\|_2}{\sqrt{m}} \\
&\leq \eta \sum_{k'=0}^{k} \frac{\sqrt{\alpha}(1 - \eta\lambda/2)^{k'/2}}{\sqrt{m}} \|y - u(0)\|_2 \\
&\leq \eta \sum_{k'=0}^{\infty} \frac{\sqrt{\alpha}(1 - \eta\lambda/2)^{k'/2}}{\sqrt{m}} \|y - u(0)\|_2 \\
&= \frac{4\sqrt{\alpha}\|y - u(0)\|_2}{\sqrt{m}\lambda},
\end{aligned}$$

where the first step follows from (28.2), the second step follows from (28.12), the third step follows from the induction hypothesis, the fourth step relaxes the summation to an infinite summation, and the last step follows from $\sum_{k'=0}^{\infty}(1-\eta\lambda/2)^{k'/2} = \frac{2}{\eta\lambda}$.

Then from Claim 28.5.4, it is sufficient to choose $\eta = \frac{\lambda}{4\alpha n}$ so that (28.13) holds for $k' = k+1$. This completes the induction step.

Over-parameterization size, lower bound on m.

We require

$$D = \frac{4\sqrt{\alpha}\|y-u(0)\|_2}{\sqrt{m}\lambda} < R = \frac{\lambda}{64n},$$

and

$$2n\exp(-mR) \leq \delta.$$

This implies that

$$\begin{aligned} m &= \Omega(\lambda^{-4}n^2\alpha\|y-u(0)\|_2^2) \\ &= \Omega(\lambda^{-4}n^3\alpha\log(m/\delta)\log^2(n/\delta)), \end{aligned}$$

where the last step follows from Claim 28.4.7. □

28.6 Quadratic Suffices

Lemma 28.6.1 (perturbed w)**.** *Let $R \in (0,1)$. Let Assumption 4 in 28.1.1 hold, i.e. for all $i \neq j$, $|x_i^\top x_j| \leq \theta/\sqrt{n}$. If $\widetilde{w}_1, \cdots, \widetilde{w}_m$ are i.i.d. generated $\mathcal{N}(0, I)$. For any set of weight vectors $w_1, \cdots, w_m \in \mathbb{R}^d$ that satisfy for any $r \in [m]$, $\|\widetilde{w}_r - w_r\|_2 \leq R$, then the $H : \mathbb{R}^{m \times d} \to \mathbb{R}^{n \times n}$ defined*

$$H(w)_{i,j} = \frac{1}{m} x_i^\top x_j \sum_{r=1}^m \mathbf{1}_{w_r^\top x_i \geq 0, w_r^\top x_j \geq 0}.$$

Then we have

$$\|H(w) - H(\widetilde{w})\|_F < 2\left(n(1+\theta^2)\right)^{1/2} R,$$

holds with probability at least $1 - n^2 \cdot \exp(-mR/10)$.

Proof. The random variable we care is

$$\begin{aligned}
\sum_{i=1}^n \sum_{j=1}^n |H(\widetilde{w})_{i,j} - H(w)_{i,j}|^2 = & \frac{1}{m^2} \sum_{i=1}^n \sum_{j=1}^n \left| x_i^\top x_j \sum_{r=1}^m (\mathbf{1}_{\widetilde{w}_r^\top x_i \geq 0, \widetilde{w}_r^\top x_j \geq 0} - \mathbf{1}_{w_r^\top x_i \geq 0, w_r^\top x_j \geq 0}) \right|^2 \\
= & B_1 + B_2,
\end{aligned}$$

where B_1, B_2 are defined as

$$\begin{aligned}
B_1 = & \frac{1}{m^2} \sum_{i=1}^n \left| \sum_{r=1}^m (\mathbf{1}_{\widetilde{w}_r^\top x_i \geq 0} - \mathbf{1}_{w_r^\top x_i \geq 0}) \right|^2, \\
B_2 = & \frac{1}{m^2} \sum_{i=1}^n \sum_{j \in [n] \setminus \{i\}} \left| x_i^\top x_j \sum_{r=1}^m (\mathbf{1}_{\widetilde{w}_r^\top x_i \geq 0, \widetilde{w}_r^\top x_j \geq 0} - \mathbf{1}_{w_r^\top x_i \geq 0, w_r^\top x_j \geq 0}) \right|^2.
\end{aligned}$$

We can further bound B_2 as

$$B_2 \le \frac{1}{m^2}\sum_{i=1}^{n}\sum_{j\in[n]\setminus\{i\}}\frac{\theta^2}{n}\left|\sum_{r=1}^{m}(\mathbf{1}_{\widetilde{w}_r^\top x_i\ge 0,\widetilde{w}_r^\top x_j\ge 0}-\mathbf{1}_{w_r^\top x_i\ge 0,w_r^\top x_j\ge 0})\right|^2$$
$$= \frac{\theta^2}{nm^2}\sum_{i=1}^{n}\sum_{j\in[n]\setminus\{i\}}\left|\sum_{r=1}^{m}(\mathbf{1}_{\widetilde{w}_r^\top x_i\ge 0,\widetilde{w}_r^\top x_j\ge 0}-\mathbf{1}_{w_r^\top x_i\ge 0,w_r^\top x_j\ge 0})\right|^2.$$

For each r,i,j, we define

$$s_{r,i,j} := \mathbf{1}_{\widetilde{w}_r^\top x_i\ge 0,\widetilde{w}_r^\top x_j\ge 0}-\mathbf{1}_{w_r^\top x_i\ge 0,w_r^\top x_j\ge 0}.$$

Then we can rewrite B_1 and B_2 as

$$B_1 = \frac{1}{m^2}\sum_{i=1}^{n}\Big(\sum_{r=1}^{m}s_{r,i,i}\Big)^2,$$
$$B_2 = \frac{\theta^2}{nm^2}\sum_{i=1}^{n}\sum_{j\in[n]\setminus\{i\}}\Big(\sum_{r=1}^{m}s_{r,i,j}\Big)^2.$$

Therefore it is sufficient to bound $\sum_{r=1}^{m}s_{r,i,j}$ simutaneously for all pair i,j. Using same technique in the proof of Theorem 28.4.2, we have

$$\Pr\left[\frac{1}{m}\sum_{r=1}^{m}s_{r,i,j}\ge 2R\right]\le\exp(-mR/10).$$

By applying union bound on all i,j pairs, we get with probability at least $1-\exp(-mR/10)$,

$$\|H(w)-H(\widetilde{w})\|_F^2 \le B_1+B_2 \le 4nR^2(1+\theta)^2.$$

which is precisely what we need. □

Table 28.4: Table of Parameters for the $m = \widetilde{\Omega}(n^2)$ result in Section 28.6. **Nt.** stands for notations.

Nt.	**Choice**	**Place**	**Comment**
λ	$:= \lambda_{\min}(H^{\text{cts}})$	Part 1 of Ass. 28.1.1	Data-dependent
α	Absolute	Part 2 of Ass. 28.1.1	Data-dependent
β	Variance	Part 3 of Ass. 28.1.1	Data-dependent
θ	Inner product	Part 4 of Ass. 28.1.1	Data-dependent
R	$\frac{\lambda}{\sqrt{n}} \cdot \min\{\frac{1}{\sqrt{\alpha}}, \frac{1}{\sqrt{1+\theta^2}}\}$	Eq. (28.15)	Maximal allowed movement of weight
D	$\frac{4\sqrt{\alpha}\|y-u(0)\|_2}{\sqrt{m}\lambda}$	Theorem 28.6.4	Actual moving distance, discrete case
η	$\lambda/(\alpha n)$	Eq. (28.11)	Step size of gradient descent
m	$(\lambda^{-2}\beta + \lambda^{-1}\alpha)\log(n/\delta)$	Theorem 28.5.1	Bounding discrete and continuous
m	$\lambda^{-4}\alpha(\alpha+\theta^2)n^2\log^3(n/\delta)$	Lemma 28.4.4 Claim 28.4.7	$D < R$ and $\|y-u(0)\|_2^2 = \widetilde{O}(n)$

Claim 28.6.2. *Assume* $R \leq \frac{\lambda}{64\sqrt{n}} \cdot \frac{1}{\sqrt{1+\theta^2}}$. *Let* $C_1 = -2\eta(y-u(k))^\top H(k)(y-u(k))$. *We have*

$$C_1 \leq -\|y-u(k)\|_2^2 \cdot \eta\lambda$$

Proof. By Lemma 28.6.1 and our choice of $R \leq \frac{\lambda}{64\sqrt{n}} \cdot \frac{1}{\sqrt{1+\theta^2}}$, We have

$$\|H(0) - H(k)\|_F \leq 2\left(n(1+\theta^2)\right)^{1/2} \cdot \frac{\lambda}{64\sqrt{n}} \cdot \frac{1}{\sqrt{1+\theta^2}} \leq \frac{\lambda}{4}.$$

Recall that $\lambda = \lambda_{\min}(H(0))$. Therefore

$$\lambda_{\min}(H(k)) \geq \lambda_{\min}(H(0)) - \|H(0) - H(k)\| \geq \lambda/2.$$

Then we have

$$(y-u(k))^\top H(k)(y-u(k)) \geq \|y-u(k)\|_2^2 \cdot \lambda/2.$$

Thus, we complete the proof. □

Claim 28.6.3. *Let* $C_2 = 2\eta(y - u(k))^\top H(k)^\perp (y - u(k))$. *We have*

$$C_2 \leq \|y - u(k)\|_2^2 \cdot 8\eta R \left(n(1+\theta^2)\right)^{1/2}.$$

holds with probability $1 - n\exp(-mR)$.

Proof. Note that

$$C_2 \leq 2\eta \cdot \|y - u(k)\|_2^2 \cdot \|H(k)^\perp\|.$$

It suffices to upper bound $\|H(k)^\perp\|$. Since $\|\cdot\| \leq \|\cdot\|_F$, then it suffices to upper bound $\|\cdot\|_F$.

For each $i \in [n]$, we define y_i as follows

$$y_i = \sum_{r=1}^{m} \mathbf{1}_{r \in \overline{S}_i}.$$

Then we have

$$\begin{aligned}
\|H(k)^\perp\|_F^2 = & \sum_{i=1}^{n}\sum_{j=1}^{n} (H(k)_{i,j}^\perp)^2 \\
= & \sum_{i=1}^{n}\sum_{j=1}^{n} \Big(\frac{1}{m}\sum_{r\in\overline{S}_i} x_i^\top x_j \mathbf{1}_{w_r(k)^\top x_i \geq 0, w_r(k)^\top x_j \geq 0}\Big)^2 \\
= & \sum_{i=1}^{n}\sum_{j=1}^{n} \Big(\frac{1}{m}\sum_{r=1}^{m} x_i^\top x_j \mathbf{1}_{w_r(k)^\top x_i \geq 0, w_r(k)^\top x_j \geq 0} \cdot \mathbf{1}_{r\in\overline{S}_i}\Big)^2 \\
= & \sum_{i=1}^{n}\sum_{j=1}^{n} \frac{|x_i^\top x_j|^2}{m^2}\Big(\sum_{r=1}^{m} \mathbf{1}_{w_r(k)^\top x_i \geq 0, w_r(k)^\top x_j \geq 0} \cdot \mathbf{1}_{r\in\overline{S}_i}\Big)^2 \\
= & B_1 + B_2,
\end{aligned}$$

where B_1 and B_2 are defined as:

$$B_1 := \sum_{i=1}^{n} \frac{1}{m^2} \Big(\sum_{r=1}^{m} \mathbf{1}_{w_r(k)^\top x_i \geq 0} \cdot \mathbf{1}_{r \in \overline{S}_i} \Big)^2,$$
$$B_2 := \sum_{i=1}^{n} \sum_{j \in [n] \setminus \{i\}} \frac{|x_i^\top x_j|^2}{m^2} \Big(\sum_{r=1}^{m} \mathbf{1}_{w_r(k)^\top x_i \geq 0, w_r(k)^\top x_j \geq 0} \cdot \mathbf{1}_{r \in \overline{S}_i} \Big)^2.$$

We bound B_1 and B_2 separately.

We first bound B_1.

$$\begin{aligned} B_1 &= \sum_{i=1}^{n} \frac{1}{m^2} \Big(\sum_{r=1}^{m} \mathbf{1}_{w_r(k)^\top x_i \geq 0} \cdot \mathbf{1}_{r \in \overline{S}_i} \Big)^2 \\ &\leq \frac{1}{m^2} \sum_{i=1}^{n} \Big(\sum_{r=1}^{m} \mathbf{1}_{r \in \overline{S}_i} \Big)^2 \\ &= \frac{1}{m^2} \sum_{i=1}^{n} y_i^2. \end{aligned}$$

Fix $i \in [n]$. The plan is to use Bernstein inequality to upper bound y_i with high probability.

First by Eq. (28.6) we have

$$\mathbb{E} \left[\mathbf{1}_{r \in \overline{S}_i} \right] \leq R.$$

We also have

$$\begin{aligned} \mathbb{E} \Big[\big(\mathbf{1}_{r \in \overline{S}_i} - \mathbb{E} \left[\mathbf{1}_{r \in \overline{S}_i} \right] \big)^2 \Big] &= \mathbb{E} \Big[\mathbf{1}_{r \in \overline{S}_i}^2 \Big] - \mathbb{E} \left[\mathbf{1}_{r \in \overline{S}_i} \right]^2 \\ &\leq \mathbb{E} \Big[\mathbf{1}_{r \in \overline{S}_i}^2 \Big] \\ &\leq R. \end{aligned}$$

Finally we have $|\mathbf{1}_{r \in \overline{S}_i} - \mathbb{E}[\mathbf{1}_{r \in \overline{S}_i}]| \leq 1$.

Notice that $\{\mathbf{1}_{r\in\overline{S}_i}\}_{r=1}^m$ are mutually independent, since $\mathbf{1}_{r\in\overline{S}_i}$ only depends on $w_r(0)$. Hence from Bernstein inequality (Lemma A.1.2) we have for all $t > 0$,

$$\Pr\left[y_i > m\cdot R + t\right] \le \exp\left(-\frac{t^2/2}{m\cdot R + t/3}\right).$$

By setting $t = 3mR$, we have

$$\Pr\left[y_i > 4mR\right] \le \exp(-mR).$$

Hence by union bound, with probability at least $1 - n\exp(-mR)$, for all $i \in [n]$,

$$y_i \le 4mR.$$

If this happens, we have

$$B_1 \le 16nR^2.$$

Next we bound B_2. We have

$$\begin{aligned}
B_2 &= \sum_{i=1}^n \sum_{j\in[n]\setminus\{i\}} \frac{|x_i^\top x_j|^2}{m^2}\Big(\sum_{r=1}^m \mathbf{1}_{w_r(k)^\top x_i\ge 0, w_r(k)^\top x_j\ge 0}\cdot \mathbf{1}_{r\in\overline{S}_i}\Big)^2 \\
&\le \frac{1}{m^2}\sum_{i=1}^n \left(\sum_{j\in[n]\setminus\{i\}} (x_i^\top x_j)^4\right)^{1/2} \cdot \left(\sum_{j\in[n]\setminus\{i\}} \Big(\sum_{r=1}^m \mathbf{1}_{w_r(k)^\top x_i\ge 0, w_r(k)^\top x_j\ge 0}\cdot \mathbf{1}_{r\in\overline{S}_i}\Big)^4\right)^{1/2} \\
&\le \frac{1}{m^2}\sum_{i=1}^n \left(\sum_{j\in[n]\setminus\{i\}} (x_i^\top x_j)^4\right)^{1/2} \left(\sum_{j\in[n]\setminus\{i\}} y_i^4\right)^{1/2} \\
&= \frac{\sqrt{n-1}}{m^2}\sum_{i=1}^n \left(\sum_{j\in[n]\setminus\{i\}} (x_i^\top x_j)^4\right)^{1/2} y_i^2 \\
&\le 16R^2\sqrt{n}\sum_{i=1}^n \left(\sum_{j\in[n]\setminus\{i\}} (x_i^\top x_j)^4\right)^{1/2},
\end{aligned}$$

where the last step happens when $y_i \leq 4mR$ for all $i \in [n]$.

Now, using the assumption $x_i^\top x_j \leq \frac{\theta}{\sqrt{n}}$ (Part 4 of Assumption 28.1.1), we have

$$B_2 \leq 16nR^2\theta^2.$$

Putting things together, we have with probability at least $1 - n\exp(-mR)$,

$$\begin{aligned} \|H(k)^\perp\|_F^2 &\leq B_1 + B_2 \\ &\leq 16nR^2(1+\theta^2). \end{aligned}$$

This gives us $\|H(k)^\perp\| \leq 4R\left(n(1+\theta^2)\right)^{1/2}$, which is precisely what we need.

□

28.6.1 Main result

Theorem 28.6.4. *Let $\lambda, \alpha, \beta, \theta$ be defined as Assumption 28.1.1. Let*

$$m = \Omega\left(\lambda^{-4} n^2 \alpha \max\{1+\theta^2, \alpha\} \log^3(n/\delta)\right).$$

We i.i.d. initialize $w_r \in \mathcal{N}(0, I)$, a_r sampled from $\{-1, +1\}$ uniformly at random for $r \in [m]$, and we set the step size $\eta = O(\lambda/(\alpha n))$ then with probability at least $1-\delta$ over the random initialization we have for $k = 0, 1, 2, \cdots$

$$\|u(k) - y\|_2^2 \leq (1 - \eta\lambda/2)^k \cdot \|u(0) - y\|_2^2.$$

Proof. **Choice of η and R.** We want to choose η and R such that

$$(1 - \eta\lambda + 8\eta R\left(n(1+\theta^2)\right)^{1/2} + 8\eta(\alpha n)^{1/2} R + \eta^2 \alpha n) \leq (1 - \eta\lambda/2). \tag{28.15}$$

Now, if we set $\eta = \frac{\lambda}{4\alpha n}$ and $R = \frac{\lambda}{64\sqrt{n}} \cdot \min\{\frac{1}{\sqrt{1+\theta^2}}, \frac{1}{\sqrt{\alpha}}\}$, we have

$$8\eta R\left(n(1+\theta^2)\right)^{1/2} + 8\eta(\alpha n)^{1/2} R \leq \frac{1}{4}\eta\lambda,$$

and $\eta^2 n^2 \leq \frac{1}{4}\eta\lambda$. This gives us

$$\|y - u(k+1)\|_2^2 \leq \|y - u(k)\|_2^2 (1 - \eta\lambda/2)$$

with probability at least $1 - 2n\exp(-mR)$.

Over-parameterization size, lower bound on m. By same analysis as in the proof of Theorem 28.5.5, we still have

$$\|w_r(k+1) - w_r(0)\|_2 \leq \frac{4\sqrt{\alpha}\|y - u(0)\|_2}{\sqrt{m}\lambda} := D$$

We require

$$D = \frac{4\sqrt{\alpha}\|y - u(0)\|_2}{\sqrt{m}\lambda} < R = \frac{\lambda}{64\sqrt{n}} \cdot \min\left\{\frac{1}{\sqrt{1+\theta^2}}, \frac{1}{\sqrt{\alpha}}\right\}$$

and

$$2n\exp(-mR) \leq \delta.$$

This implies that

$$\begin{aligned} m &= \Omega(\lambda^{-4} n\alpha \|y - u(0)\|_2^2 \max\{1+\theta^2, \alpha\}) \\ &= \Omega(\lambda^{-4} n^2 \alpha \cdot \max\{1+\theta^2, \alpha\} \cdot \log(m/\delta)\log^2(n/\delta)), \end{aligned}$$

where the last step follows from Claim 28.4.7. □

Chapter 29

Longest Common Subsequence I

Given a pair of n-character strings, the problems of computing their Longest Common Subsequence and Edit Distance have been extensively studied for decades. For exact algorithms, LCS and Edit Distance (with character insertions and deletions) are equivalent; the state of the art running time is (almost) quadratic in n, and this is tight under plausible fine-grained complexity assumptions. But for approximation algorithms the picture is different: there is a long line of works with improved approximation factors for Edit Distance, but for LCS (with binary strings) only a trivial 1/2-approximation was known. In this work we give a reduction from approximate LCS to approximate Edit Distance, yielding the first efficient $(1/2 + \epsilon)$-approximation algorithm for LCS for some constant $\epsilon > 0$.

This part is based on previous following publication

- Aviad Rubinstein, Zhao Song

  Reducing approximate Longest Common Subsequence to approximate Edit Distance.

  Manuscript 2019 [RS19b]

29.1 Introduction

In this work we consider two of the most ubiquitous measures of similarity between a pair of strings: the longest common subsequence (LCS) and the edit distance. The LCS of two n-character strings A and B is simply their longest (not necessarily contiguous) common substring. Edit distance is the minimum number of character insertions, deletions, and substitutions required to transform A to B. In fact, under a slightly more restricted definition that does not allow substitutions[1], the two measures are complements and the problems of computing them exactly are equivalent.

There is a textbook dynamic programming algorithm for computing LCS (or edit distance) than runs in $O(n^2)$ time, and a slightly faster $O(n^2/\log^2(n))$-time algorithm due to Masek and Paterson [MP80]. Finding faster algorithms is a central and long standing open problem both in theory and in practice (e.g. Problem 35 of [Knu72]). Under plausible fine-grained complexity assumptions such as SETH, neither problem can be computed much faster [AWW14, ABW15, BI15, BK15, AHWW16].

For (multiplicative) approximation, the two problems are no longer equivalent. For edit distance, there is a long sequence of approximation algorithms with improving factors [BYJKK04, BES06, AO12, AKO10, BEG+18]; in particular, [CDG+18] gives a constant factor approximation in truly sub-quadratic time. For LCS with alphabet size $|\Sigma|$, in contrast, there is a trivial $1/|\Sigma|$-approximation, and no better algorithms are known (for large alphabet[2] there are some hardness of approximation results [AB17, AR18, CGL+19] and also

[1] Since the definitions are equivalent up to a factor of 2 (each substitution is an insertion and a deletion), this difference is irrelevant as we consider constant factor approximations of edit distance.

[2] One may also consider the case of intermediate alphabet size, e.g. $\Sigma = \{A, C, G, T\}$. It is plausible that

approximation algorithms with non-trivial polynomial factors [HSSS19, RSSS19]).

In this work we focus on binary strings, where the trivial algorithm gives a $(1/|\Sigma| = 1/2)$-approximation. Breaking this $1/2$ barrier is a well-known open problem in this area. Our main result is a fine-grained reduction that implies obtaining a $1/2 + \epsilon$-approximation for binary LCS (for some constant $\epsilon > 0$) is no harder than approximating edit distance to within some constant factor.

Theorem 29.1.1 (Reduction: approximate ED implies approximate LCS)**.**

Suppose that there exists a constant c and an approximate edit distance algorithm that runs in time $T(n)$ and, given two binary strings A, B of length n, returns an estimate $\widetilde{\mathrm{ED}}(A, B) \in [\mathrm{ED}(A, B), c \cdot \mathrm{ED}(A, B) + o(n)]$. Then there exists a fixed constant $\epsilon = \epsilon(c) \in (0, 1/2)$ and a deterministic approximation algorithm for longest common subsequence that runs in deterministic $T(n) + O(n)$ and approximates $\mathrm{LCS}(A, B)$ to within a $(1/2 + \epsilon)$-approximation factor.

Remark 29.1.1. We state the above theorem in terms of estimating the edit distance or length of the LCS. If the edit distance algorithm can efficiently compute the transformation (this assumption is almost wlog by [CGKK18]), then our algorithm can also efficiently compute the common string.

As mentioned above, the recent breakthrough of [CDG+18] gives a constant factor approximation of edit distance in truly-subquadratic ($\widetilde{O}(n^{2-2/7})$) time. By plugging their algorithm into our reduction, we would obtain $(1/2+\epsilon)$-approximation algorithm for binary

our framework can give a $1/|\Sigma| + \epsilon$-approximation in this case as well, but the proof may become more complicated.

LCS with the same running time. By applying our reduction to the even more recent approximation algorithms for edit distance[3] that run in near-linear time [KS19, BR19], we obtain the following stronger corollary:

Corollary 29.1.2 (Approximate LCS)**.** *For every constant $\delta > 0$ there exists a constant $\epsilon > 0$ such that, given two binary strings $A, B \in \{0,1\}^n$, there is an algorithm that runs in $O(n^{1+\delta})$ time and $\mathrm{LCS}(A,B)$ to within a $(1/2+\epsilon)$-factor.*

Technical preview

The crux of our algorithm is analyzing first order statistics (counts of 0s and 1s) of the input strings (A, B) and their substrings. We begin with a few simple observations. Below, we normalize ED and LCS so that they're always between 0 and 1 (as opposed to 0 and n).

- If the strings are balanced, namely have the same number of 0s and 1s, we know that $\mathrm{LCS}(A,B) \in [1/2, 1]$. If the strings are very close, say $\mathrm{LCS}(A,B) \geq (1-\delta)$ for sufficiently small $\delta > 0$, we can use the assumed edit distance algorithm as a black box and find a common substring of length $\geq (1 - O(\delta))$. On the converse if the substring returned by the algorithm is shorter than $(1-O(\delta))$, we know that $\mathrm{LCS}(A,B) < 1-\delta$, and thus returning an all-1 string of length $1/2$ is a $(1/2+2\delta)$-approximation.

- If A is balanced and B has e.g. 10% 0s and 90% 1s, we know that $\mathrm{LCS}(A,B) \in [0.5, 0.6]$, so simply returning the all-1 string of length $1/2$ is a $5/6$-approximation. The same holds for most ways in which one or both strings are unbalanced.

[3]The near-linear time approximation algorithms for edit distance [KS19, BR19] also incur a sublinear additive error term, but that is OK for our reduction.

- However there is one difficult case when the string are *perfectly unbalanced*, e.g. A has 99% 0s and B has 99% 1s. Now the first order statistics over the entire strings only tell us that $\mathrm{LCS}(A, B) \in [0.01, 0.02]$, so the trivial approximation doesn't beat 1/2. On the other hand, the edit distance is at least 0.98, so even a 1.1-approximation algorithm for edit distance wouldn't give us a non-trivial guarantee for this case.

Our main technical contribution is a careful analysis of this last case (and its many sub-cases).

29.2 Preliminaries

For strings $x, y \in \{0,1\}^m$ for $m \leq n$, we use $1(x)$ to denote the number of 1 in x, $0(x)$ to denote the number of 0 in x, and $\mathrm{LCS}(x, y)$ to denote the length of their longest common subsequence. All of these function are normalized w.r.t. the length of the original input to our main algorithm, n; in particular we always have $0(x), 1(x), \mathrm{LCS}(x, y) \in [0, m/n]$.

Fact 29.2.1.

$$\mathrm{LCS}(A, B) \leq \min\{0(A), 0(B)\} + \min\{1(A), 1(B)\}.$$

Parameters $\alpha, \beta, \gamma, \delta$

In the proof we consider the following parameters:

α We define $\alpha := \min\{1(A), 1(B), 0(A), 0(B)\}$. Notice that α may be very small, and even approaching 0 as a function of n. We assume wlog that this minimum is attained by $1(A) = \alpha$.

β The parameter β will represent a robustness parameter for some of our bounds. We take $\beta = \Theta(\alpha)$, but it may be smaller by an arbitrary constant factor.

γ The parameter $\gamma \in (0, 1)$ is a constant that depends on the approximation factor c of the approximation algorithm for edit distance that we assume. We choose β sufficiently small such that $\gamma\alpha \gg \beta$.

δ The parameter δ represents the deviation from "perfectly unbalanced" case (see Lemma 29.3.1). It is an arbitrary small constant. In particular, $\delta\alpha \ll \beta$. It is sufficiently small

that for succinctness of representation we'll simply omit it (as if it were zero) after Lemma 29.3.1.

Subroutines

Our reduction will assume the availability of an algorithm ApproxED which takes as input two strings A, B of length n and outputs $1-\widetilde{\mathrm{ED}}(A,B)$ where $\widetilde{\mathrm{ED}}(A,B) \in [\mathrm{ED}(A,B), c \cdot \mathrm{ED}(A,B) + o(1)]$.

In addition, we also define three trivial algorithms; they all run in time linear in length of input string.

Definition 29.2.1 (Match)**.** Given input string A and B, and a symbol $\sigma \in \Sigma$. The algorithm $\textsc{Match}(A, B, \sigma)$ will output a string C where every character is σ and the length of C is $\min\{\sigma(A), \sigma(B)\}$. This algorithm takes $O(|A| + |B|)$ time.

Definition 29.2.2 (BestMatch)**.** Given input string A and B. The algorithm $\textsc{BestMatch}(A, B)$ will take the longest one of $\textsc{Match}(A, B, 0)$ and $\textsc{Match}(A, B, 1)$. This algorithm also takes $O(|A| + |B|)$ time.

Definition 29.2.3 (Greedy)**.** Given input string A_1, A_2 and B. The algorithm $\textsc{Greedy}(A_1, A_2, B)$ will find the optimal contiguous partition $B = B_1 \cup B_2$ so as to maximize $\textsc{BestMatch}(A_1, B_1) + \textsc{BestMatch}(A_2, B_2)$. This algorithm also takes $O(|A| + |B|)$ time.

Below, we slightly abuse notation and refer to the above algorithms (ApproxED, Match, BestMatch, Greedy) both when we want their output to be the actual common string, and the length. Which output we need will be clear from context.

29.3 Reducing to perfectly unbalanced case

In this section we formalize the intuition from the introduction that BestMatch gives a better-than-1/2-approximation unless $1(A) \approx 0(B)$.

Lemma 29.3.1 (Reduction to perfectly unbalanced case)**.**

If $|1(A) - 0(B)| > \delta \min\{0(A), 0(B), 1(A), 1(B)\}$*, then*

$$\textsc{BestMatch}(A, B) \geq (1/2 + \delta/6)\,\mathrm{LCS}(A, B).$$

Proof. Assume wlog[4] that $1(A) = \min\{0(A), 0(B), 1(A), 1(B)\}$. Then we have,

$$\begin{aligned}
&\textsc{BestMatch}(A, B) \\
&= \textsc{Match}(A, B, 0) \\
&= \min\{0(B), 0(A)\} \\
&= 0(B) && \text{(By assumption } 1(A) \leq 1(B)\text{)} \\
&> (1 + \delta)1(A) && \text{(By premise of lemma)} \\
&= (1 + \delta)\min\{1(A), 1(B)\} \\
&\geq (1 + \delta)\big(\mathrm{LCS}(A, B) - \min\{0(A), 0(B)\}\big) && \text{(Fact 29.2.1)} \\
&= (1 + \delta)\big(\mathrm{LCS}(A, B) - \textsc{BestMatch}(A, B)\big).
\end{aligned}$$

[4]This is wlog since $|1(A) - 0(B)| = |0(A) - 1(B)|$, so the premise of this lemma is symmetric.

Therefore,

$$\begin{aligned}\textsc{BestMatch}(A,B) &\geq \frac{1+\delta}{2+\delta}\,\mathrm{LCS}(A,B)\\ &\geq (1/2+\frac{\delta}{4+2\delta})\,\mathrm{LCS}(A,B)\\ &\geq (1/2+\delta/6)\,\mathrm{LCS}(A,B).\end{aligned}$$

□

We henceforth assume wlog that

$$|0(A)-1(B)| \leq \delta \min\{0(A),0(B),1(A),1(B)\}. \tag{29.1}$$

For ease of presentation, we henceforth omit δ from our calculations, i.e. we'll assume that $\delta = 0$. It will be evident that modifying any of our inequalities by factors in $[\pm\delta\alpha]$ will not affect the proofs.

Eq. (29.1) is very important in our analysis, but it does not rule out the perfectly balanced case, namely $0(A) \approx 0(B) \approx 1(A) \approx 1(B) \approx 1/2$.

Lemma 29.3.2 (Ruling out the perfectly balanced case)**.**

Let $\beta', \gamma > 0$ be sufficiently small constants[5]*. If $0(A) \in [1/2 \pm \beta']$, then*

$$\max\{\textsc{BestMatch}(A,B), \textsc{ApproxED}(A,B)\} \geq (1/2+\gamma)\,\mathrm{LCS}(A,B). \tag{29.2}$$

Proof. By Eq. (29.1), the premise implies that $1(B) \in [1/2 \pm \beta']$, and by symmetry also $1(A), 0(B) \in [1/2 \pm \beta']$. Therefore, $\textsc{BestMatch}(A,B) \geq 1/2 - \beta'$.

[5]In particular, in Eq. (29.3) we require that $\beta' + \gamma < \frac{1}{4c+2}$, where c is the approximation factor of the edit distance algorithm.

Suppose that $\textsc{BestMatch}(A, B)$ isn't big enough to satisfy Eq. (29.2) (otherwise we're done). Then,

$$\mathrm{LCS}(A, B) > 2\Big(\textsc{BestMatch}(A, B) - \gamma\Big) \geq 2\Big(1/2 - (\beta' + \gamma)\Big) = 1 - 2(\beta' + \gamma).$$

Thus also

$$\mathrm{ED}(A, B) = 1 - \mathrm{LCS}(A, B) \leq 2(\beta' + \gamma).$$

Therefore, by its approximation guarantee, we have that

$$\textsc{ApproxED}(A, B) \geq 1 - c \cdot \mathrm{ED}(A, B) - o(1) \geq 1 - 2c(\beta' + \gamma) - o(1) \geq 1/2 + \gamma. \quad (29.3)$$

(The latter inequality follows by choosing β' and γ sufficiently small.) □

Setting $\beta' = 10\beta$, we henceforth assume wlog that

$$0(A), 1(A), 0(B), 1(B) \notin [1/2 \pm 10\beta]. \quad (29.4)$$

29.4 Perfectly unbalanced strings

In this section we build on our assumptions from Eq. (29.1) and Eq. (29.4) from the previous section to complete the proof of our reduction.

Recall that we define $\alpha := 1(A) < 1/2$, and by Eq. (29.1), we also have $0(B) = \alpha$. We partition each string into three contiguous substrings, where the extreme left and right substring are each of length α:

$$A = L_A \cup M_A \cup R_A$$

$$B = L_B \cup M_B \cup R_B$$

$$|L_A| = |R_A| = |L_B| = |R_B| = \alpha$$

$$|M_A| = |M_B| = 1 - 2\alpha.$$

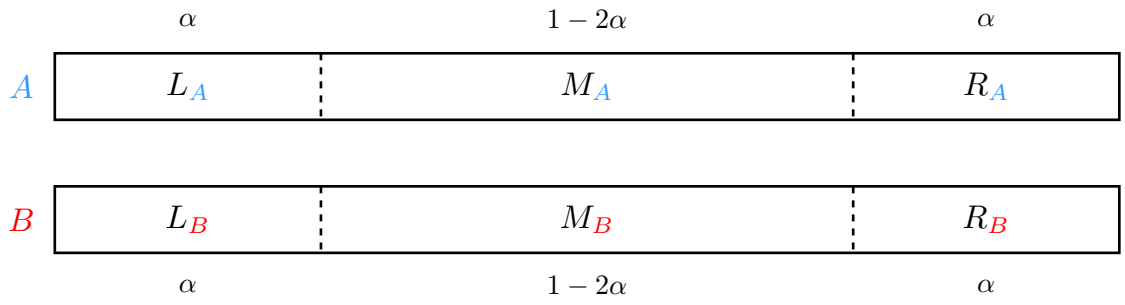

Figure 29.1

We consider six cases for the proportions of 1's and 0's in R_A, L_A, R_B, L_B as in Eq. (29.5). By Table 29.1, we know that those six cases cover all the possibilities.

Our six cases can be summarized in the following equation,

$$\begin{cases} 1(R_B) \leq \alpha/2+2\beta, 0(R_A) \leq \alpha/2+2\beta & \text{Case 1} \\ 1(L_B) \leq \alpha/2+2\beta, 0(L_A) \leq \alpha/2+2\beta & \text{Case 2} \\ 1(R_B) \leq \alpha/2+\beta, 1(L_B) \leq \alpha/2+\beta, 0(L_A) > \alpha/2+2\beta, 0(R_A) > \alpha/2+2\beta & \text{Case 3} \\ 1(R_B) > \alpha/2+2\beta, 1(L_B) > \alpha/2+2\beta, 0(L_A) \leq \alpha/2+\beta, 0(R_A) \leq \alpha/2+\beta & \text{Case 4} \\ 1(R_B) > \alpha/2+\beta, 0(L_A) > \alpha/2+\beta & \text{Case 5} \\ 1(L_B) > \alpha/2+\beta, 0(R_A) > \alpha/2+\beta & \text{Case 6} \end{cases} \tag{29.5}$$

Table 29.1: Fill all the six cases in Eq. (29.5) into the whole space. Note that $1+2+3$ means the combination of 1, 2 and 3 covers it. $5, 6$ means any one of them covers it.

	$0(R_A) \leq \alpha/2+\beta$, $0(L_A) \leq \alpha/2+\beta$	$0(R_A) \leq \alpha/2+\beta$, $0(L_A) > \alpha/2+\beta$	$0(R_A) > \alpha/2+\beta$, $0(L_A) \leq \alpha/2+\beta$	$0(R_A) > \alpha/2+\beta$, $0(L_A) > \alpha/2+\beta$
$1(R_B) \leq \alpha/2+\beta$, $1(L_B) \leq \alpha/2+\beta$	1,2	1	2	1+2+3
$1(R_B) \leq \alpha/2+\beta$, $1(L_B) > \alpha/2+\beta$	1	1	6	6
$1(R_B) > \alpha/2+\beta$, $1(L_B) \leq \alpha/2+\beta$	2	5	2	5
$1(R_B) > \alpha/2+\beta$, $1(L_B) > \alpha/2+\beta$	1+2+4	5	6	5,6

Case 1: $1(R_B) \leq \alpha/2 + 2\beta$**,** $0(R_A) \leq \alpha/2 + 2\beta$

We split this case into three sub-cases, as follows:

$$\begin{cases} 1(R_B) \in [\alpha/2 \pm 4\beta],\ 0(R_A) \in [\alpha/2 \pm 4\beta] & \text{Case 1(a)} \\ 1(R_B) < \alpha/2 - 4\beta,\ 0(R_A) \leq \alpha/2 + 2\beta & \text{Case 1(b)} \\ 1(R_B) \leq \alpha/2 + 2\beta,\ 0(R_A) < \alpha/2 - 4\beta & \text{Case 1(c)} \end{cases} \tag{29.6}$$

Case 1(a): $1(R_B) \in [\alpha/2 \pm 4\beta]$**,** $0(R_A) = [\alpha/2 \pm 4\beta]$

At a high level, we want to split the original problem into two subproblems:

left-middle $(L_A \cup M_A, L_B \cup M_B)$;

right (R_A, R_B).

Running BestMatch on the left-middle subproblem gives a (1/2)-approx; the right subproblem is (approximately) balanced so Lemma 29.3.2 (i.e. taking the better of BestMatch and ApproxED) gives better-than-1/2. The visualization of this case is presented in Figure 29.2.

We first want to upper bound $\text{LCS}(A, B)$ as roughly the sum of LCSs of the two subproblems, but in general this may not be the case. Fix an optimal matching μ corresponding to a longest common substring between A and B. Assume wlog (by symmetry w.r.t. switching A and B) that $\mu(R_A) \subseteq R_B$, i.e. the LCS does not match any R_A characters with characters from $L_B \cup M_B$. μ induces a new partition of B into two[6] contiguous

[6]Note that we do not define a $\widehat{M_B}$.

substrings $\widehat{L_B} \cup \widehat{R_B}$ such that $\mu(R_A) \subseteq \widehat{R_B} \subseteq R_B$. By optimality of μ, we have

$$\mathrm{LCS}(A, B) = \mathrm{LCS}(L_A \cup M_A, \widehat{L_B}) + \mathrm{LCS}(R_A, \widehat{R_B}). \tag{29.7}$$

Applying Fact 29.2.1 to both terms on the RHS, we have

$$\begin{aligned}\mathrm{LCS}(A, B) \leq & \underbrace{\min\{1(L_A \cup M_A), 1(\widehat{L_B})\} + \min\{0(L_A \cup M_A), 0(\widehat{L_B})\}}_{=X} \\ & + \underbrace{\min\{1(R_A), 1(\widehat{R_B})\} + \min\{0(R_A), 0(\widehat{R_B})\}}_{=Y}.\end{aligned} \tag{29.8}$$

We henceforth denote the left and right contributions to the bound on the LCS by X and Y respectively. (So $\mathrm{LCS}(A, B) \leq X + Y$.) We also define:

$$Z := \max\Big\{ \min\{1(L_A \cup M_A), 1(\widehat{L_B})\}, \min\{0(L_A \cup M_A), 0(\widehat{L_B})\}\Big\}.$$

(Observe that $Z \geq X/2$.)

We now prove a lower bound on the LCS that our algorithm can find.

$$\begin{aligned}\textsc{Greedy}(L_A \cup M_A, R_A, B) \geq & \max\Big\{ \min\{1(L_A \cup M_A), 1(\widehat{L_B})\}, \min\{0(L_A \cup M_A), 0(\widehat{L_B})\}\Big\} \\ & + \max\Big\{ \min\{1(R_A), 1(\widehat{R_B})\}, \min\{0(R_A), 0(\widehat{R_B})\}\Big\} \\ \geq & Z + Y/2.\end{aligned} \tag{29.9}$$

We break into sub-cases, depending on the value of Z.

Case 1(a-i): $Z > \alpha/2 + 10\beta$ In this case, observe that

$$\begin{aligned}
X - Z =& \min\{1(L_A \cup M_A), 1(\widehat{L_B}), 0(L_A \cup M_A), 0(\widehat{L_B})\} \\
\leq& 1(L_A \cup M_A) \\
=& \alpha - 1(R_A) && (\alpha = 1(A)) \\
\leq& \alpha/2 + 4\beta && \text{(Case 1(a) assumption)} \\
<& Z - 6\beta && \text{(Case 1(a-i) assumption)}
\end{aligned}$$

Therefore, $Z > X/2 + 3\beta$. Combining with Eq. (29.8) and (29.9), we have that

$$\textsc{Greedy}(L_A \cup M_A, R_A, B) \geq Z + Y/2 > X/2 + Y/2 + 3\beta \geq \mathrm{LCS}(A, B)/2 + 3\beta.$$

Case 1(a-ii): $Z \leq \alpha/2 + 10\beta$ By Eq. (29.7), we have

$$\begin{aligned}
\mathrm{LCS}(A, B) \leq& X + \mathrm{LCS}(R_A, \widehat{R_B}) \\
\leq& 2Z + \mathrm{LCS}(R_A, \widehat{R_B}) && (Z \geq X/2) \\
\leq& \alpha + 20\beta + \mathrm{LCS}(R_A, \widehat{R_B}) && \text{(Case 1(a-ii) assumption)} \\
\leq& \alpha + 20\beta + \mathrm{LCS}(R_A, R_B). && (\widehat{R_B} \subseteq R_B) \qquad (29.10)
\end{aligned}$$

For our purposes, this is effectively as good as bounding $\mathrm{LCS}(A, B)$ by the sum of LCSs of the left-middle and right subproblems.

We run BestMatch on the left-middle subproblem. We have that

$$\begin{aligned}
& \textsc{BestMatch}(L_A \cup M_A, L_B \cup M_B) \\
\geq\ & \min\{0(L_A \cup M_A), 0(L_B \cup M_B)\} \\
\geq\ & \alpha/2 - 4\beta && \text{(Case 1(a) assumption).}
\end{aligned}$$

We run BestMatch and ApproxED on R_A, R_B and take the better of the two outcomes. We apply Lemma 29.3.2 to strings R_A, R_B with $\beta' = 4\beta/\alpha$. (Notice that by Case 1(a) assumption, they are guaranteed to be approximately balanced to within $\pm 4\beta$, or a relative $\pm 4\beta/\alpha$.) We therefore have that

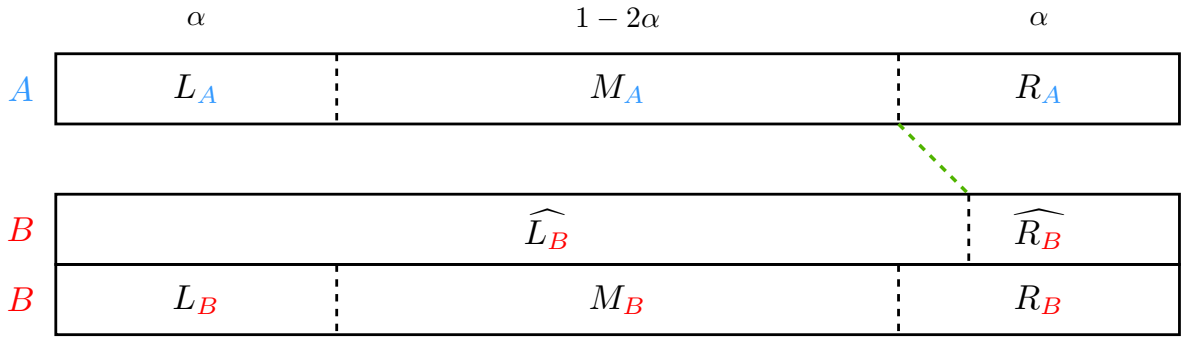
$$\begin{aligned}
&\max\{\textsc{BestMatch}(R_A, R_B), \textsc{ApproxED}(R_A, R_B)\} \\
&\geq (1/2 + \gamma)\,\mathrm{LCS}(R_A, R_B) && \text{(Lemma 29.3.2)} \\
&\geq \mathrm{LCS}(R_A, R_B)/2 + \gamma\alpha/2 - O(\beta\gamma) && (\mathrm{LCS}(R_A, R_B) \geq \alpha/2 - O(\beta)) \\
&\geq \mathrm{LCS}(R_A, R_B)/2 + \gamma\alpha/2 - O(\beta). && (\gamma \leq 1)
\end{aligned}$$

So in total, our algorithm finds a common substring of length at least

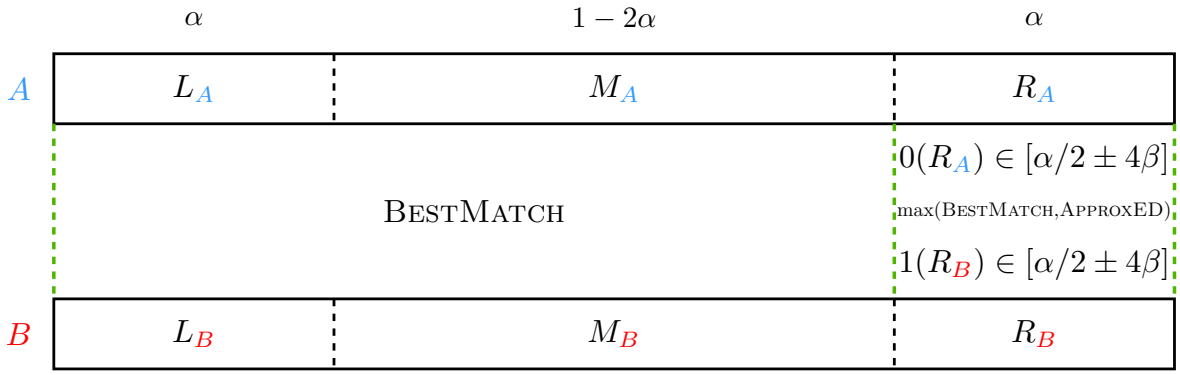
$$\begin{aligned}
&\big(\alpha + \mathrm{LCS}(R_A, R_B)\big)/2 + \gamma\alpha - O(\beta) \\
&\geq \mathrm{LCS}(A, B)/2 + \gamma\alpha/2 - O(\beta) && \text{(Eq. (29.10))} \\
&\geq \mathrm{LCS}(A, B)/2 + \frac{2}{6}\gamma\alpha && (\gamma\alpha \gg \beta) \\
&\geq (1/2 + \gamma/6)\,\mathrm{LCS}(A, B). && (\mathrm{LCS}(A, B) \leq 2\alpha)
\end{aligned}$$

Case 1(b): $1(R_B) < \alpha/2 - 4\beta$**,** $0(R_A) \leq \alpha/2 + 2\beta$

Fix an optimal matching μ. We further split this case into two sub-cases, depending on whether $\mu(R_A) \subseteq R_B$ or $R_B \subseteq \mu(R_A)$. (In Case 1(a) we could assume the former wlog by symmetry. Also notice that in general both may occur simultaneously.)



(a) Partition $(\widehat{L_B}, \widehat{R_B})$ created by GREEDY$(L_A \cup M_A, R_A, B)$



(b) BESTMATCH$(L_A \cup M_A, L_B \cup M_B)$ and max(BESTMATCH(R_A, R_B), APPROXED(R_A, R_B))

Figure 29.2: Visualization of Case 1(a) which is $0(R_A) \in [\alpha/2 \pm 4\beta]$ and $1(R_B) \in [\alpha/2 \pm 4\beta]$. If $0(\widehat{L_B}) > \alpha/2 + 10\beta$, we use GREEDY result. If $0(\widehat{L_B}) \leq \alpha/2 + 10\beta$, we use the result BESTMATCH+ max(BESTMATCH, APPROXED).

If $\mu(R_A) \subseteq R_B$, define the partition $\widehat{L_B}, \widehat{R_B}$ as in Case 1(a). We have

$$\begin{aligned}
\mathrm{LCS}(A, B) &= \mathrm{LCS}(L_A \cup M_A, \widehat{L_B}) + \mathrm{LCS}(R_A, \widehat{R_B}) \\
&\leq \underbrace{1(L_A \cup M_A)}_{\leq \alpha/2+2\beta} + \underbrace{0(\widehat{L_B}) + 0(\widehat{R_B})}_{\leq \alpha} + \underbrace{1(\widehat{R_B})}_{\leq \alpha/2-4\beta} && \text{(Fact 29.2.1)} \\
&\leq 2\alpha - 2\beta. && (29.11)
\end{aligned}$$

Similarly, if $\mu(R_A) \supseteq R_B$, we can define an analogous partition of A into $\widehat{L_A}, \widehat{R_A}$:

$$\begin{aligned}\text{LCS}(A, B) &= \text{LCS}(\widehat{L_A}, L_B \cup M_B) + \text{LCS}(\widehat{R_A}, R_B) \\ &\leq \underbrace{0(L_B \cup M_B)}_{\leq \alpha/2 - 4\beta} + \underbrace{1(\widehat{L_A}) + 1(\widehat{R_A})}_{\leq \alpha} + \underbrace{1(R_B)}_{\leq \alpha/2 - 4\beta} && \text{(Fact 29.2.1)} \\ &\leq 2\alpha - 8\beta. && (29.12)\end{aligned}$$

Either way, we have that $\text{LCS}(A, B) \leq 2\alpha - 2\beta$; therefore $\textsc{Match}(A, B, 0) = \alpha$ guarantees a better-than-1/2-approximation.

Case 1(c): $1(R_B) \leq \alpha/2 + 2\beta$**,** $0(R_A) < \alpha/2 - 4\beta$

Follows analogously to Case 1(b).

Case 2: $1(L_B) \leq \alpha/2 + \beta$**,** $0(L_A) \leq \alpha/2 + \beta$

We reverse the order of string A and B, then the proof is the same as Case 1.

Case 3: $1(R_B) \leq \alpha/2 + \beta$**,** $1(L_B) \leq \alpha/2 + \beta$**,** $0(L_A) > \alpha/2 + 2\beta$ **and** $0(R_A) > \alpha/2 + 2\beta$

We visualize this case in Figure 29.3a.

We show that simple applications of Match to the left, middle, and right substrings can guarantee a common string of at least $\alpha + 2\beta \geq \text{LCS}(A, B)/2 + 2\beta$.

For the middle substrings, observe that $1(M_A) = 1(A) - 1(R_A) - 1(L_A) > 4\beta$. We

can also lower bound $1(M_B)$ by:

$$\begin{aligned} 1(M_B) &= 1(B) - 1(L_B) - 1(R_B) \\ &> \alpha + 20\beta - 1(L_B) - 1(R_B) && \text{(Eq. (29.4))} \\ &\geq 18\beta && \text{(Premise of Case 3).} \end{aligned}$$

Therefore,

$$\textsc{Match}(M_A, M_B, 1) = \min\{1(M_A), 1(M_B)\} \geq 4\beta. \tag{29.13}$$

For the left substrings, observe that $0(L_B) = |L_B| - 1(L_B) > \alpha/2 - \beta$. Therefore,

$$\textsc{Match}(L_A, L_B, 0) = \min\{0(L_A), 0(L_B)\} \geq \alpha/2 - \beta. \tag{29.14}$$

Similarly,

$$\textsc{Match}(R_A, R_B, 0) = \min\{0(R_A), 0(R_B)\} \geq \alpha/2 - \beta. \tag{29.15}$$

Summing up Eq. (29.13),(29.14),(29.15), our algorithm obtains a common string of length at least $\alpha + 2\beta$.

Case 4: $1(R_B) > \alpha/2 + 2\beta$**,** $1(L_B) > \alpha/2 + 2\beta$**,** $0(L_A) \leq \alpha/2 + \beta$ **and** $0(R_A) \leq \alpha/2 + \beta$

We visualize this case in Figure 29.3b.

If we switch A and B, then the proof is the same as Case 3.

Case 5: $1(R_B) > \alpha/2 + \beta$**, and** $0(L_A) > \alpha/2 + \beta$

We visualize this case in Figure 29.3c.

We apply MATCH to two subproblems to obtain a common substring of length greater than $\alpha + 2\beta \geq \text{LCS}(A, B)/2 + 2\beta$.

Observe that $0(L_B \cup M_B) = 0(B) - 0(R_B) > \alpha/2 + \beta$.

$$\text{MATCH}(L_A, L_B \cup M_B, 0) = \min\{0(L_A), 0(L_B \cup M_B)\} > \alpha_/2 + \beta.$$

By an analogous argument,

$$\text{MATCH}(M_A \cup R_A, R_B, 1) = \min\{1(M_A \cup R_A), 1(R_B)\} > \alpha/2 + \beta.$$

Case 6: $1(L_B) > \alpha/2 + \beta$**, and** $0(R_A) > \alpha/2 + \beta$

We visualize this case in Figure 29.3d.

We reverse the oder of string A and B, then the proof is the same as Case 5.

Chapter 30

Longest Common Subsequence II

Longest common subsequence (LCS) is a classic and central problem in combinatorial optimization. While LCS admits a quadratic time solution, recent evidence suggests that solving the problem may be impossible in truly subquadratic time. A special case of LCS wherein each character appears at most once in every string is equivalent to the longest increasing subsequence problem (LIS) which can be solved in quasilinear time. In this work, we present novel algorithms for approximating LCS in truly subquadratic time and LIS in truly sublinear time. Our approximation factors depend on the ratio of the optimal solution size over the input size. We denote this ratio by λ and obtain the following results for LCS and LIS without any prior knowledge of λ.

- A truly subquadratic time algorithm for LCS with approximation factor $O(\lambda^3)$.
- A truly sublinear time algorithm for LIS with approximation factor $O(\lambda^3)$.

Triangle inequality was recently used by Boroujeni *et al.* [BEG+18] and Chakraborty *et al.* [CDG+18] to present new approximation algorithms for edit distance. Our techniques for LCS extend the notion of triangle inequality to non-metric settings.

This part is based on previous following publication

  Approximation Algorithms for LCS and LIS with Truly Improved Running Times. FOCS 2019 [RSSS19]

30.1 Introduction

In this paper, we consider three of the most classic problems in combinatorial optimization: the longest common subsequence (LCS), the edit distance (ED), and the longest increasing subsequence (LIS). The LCS of two strings A and B is simply their longest (not necessarily contiguous) common subsequence. The edit distance is defined as the minimum number of character deletions, insertions, and substitutions required to transform A into B. For the purpose of our discussion, we consider a more restricted definition of edit distance where substitutions are not allowed[1]. Longest increasing subsequence is equivalent to a special case of LCS where the input strings are permutations. All three problems are very fundamental and have been subject to a plethora of studies in the past few decades and specially in recent years [LMS98, BYJKK04, BES06, AO09, AKO10, SS10, BI15, ABW15, AHWW16, AB17, AR18, CGL+19, BEG+18, CDG+18, HSSS19].

If the strings have length n, both LCS and ED can be solved in quadratic time ($O(n^2)$) with dynamic programming. These running times are slightly improved to $O(n^2/\log^2(n))$ by Masek and Paterson [MP80], however, efforts to improve the running time to $O(n^{2-\Omega(1)})$ for either edit distance or LCS were all futile.

In recent years, our understanding of the source of complexity for these problems tremendously improved thanks to a sequence of fine-grained complexity developments [ABW15, AHWW16]. We now know that assuming the strong exponential time hypothesis (SETH) [ABW15], or even weaker assumptions such as the orthogonal vectors conjecture (OVC) [ABW15] or branching-program-SETH [AHWW16], there are no truly sub-quadratic[2] time algorithms for

[1] Alternatively, the cost of a substitution is doubled as it requires a deletion and an insertion.
[2] By *truly sub-quadratic* we mean $O(n^{2-\epsilon})$, for any constant $\epsilon > 0$

LCS. Similar results also hold for edit distance [BI15].

Indeed, the classic approach to break the quadratic barrier for these problems is approximation algorithms. Note that for (multiplicative) approximations, LCS and edit distance are no longer equivalent (much like we have a 2-approximation algorithm for Vertex Cover, but Independent Set is **NP**-hard to approximate within near-linear factors).

For edit distance, an $\widetilde{O}(n+\Delta^2)$-time algorithm of [LMS98] (where Δ is the true edit distance between the strings) implies a linear-time $\sqrt{n}$-approximation algorithm. The approximation factor has been significantly improved in a series of works to $O(n^{3/7})$ [BYJKK04], to $O(n^{0.34})$ [BES06], to $O(2^{\widetilde{O}(\sqrt{\log n})})$ [AO09][3], and finally to polylogarithmic [AKO10]. A recent work of Boroujeni *et al.* [BEG+18] obtains a constant factor approximation quantum algorithm for edit distance that runs in truly subquadratic time. Finally, the breakthrough of Chakraborty *et al.* [CDG+18] gave a classic (randomized) constant factor approximation for edit distance in truly subquadratic time. A key component in both of the latest constant factor approximation algorithms is the application of triangle inequality (for edit distance between certain substrings of the input). A particular challenge in extending these ideas to LCS is that LCS is not a metric and in particular does not satisfy the triangle inequality.

Our understanding of the complexity of approximate solutions for LCS is embarrassingly limited. For general strings, there are several linear-time $1/\sqrt{n}$-approximation algorithms based on sampling techniques. For alphabet size $|\Sigma|$, there is a trivial $1/|\Sigma|$-approximation algorithm that runs in linear time. Whether or not these approximation factors can be improved by keeping the running time subquadratic is one of the central

[3]We define $\widetilde{O}(f)$ to be $f \cdot \log^{O(1)}(f)$.

problems in fine-grained complexity. Very recently, both the general $1/\sqrt{n}$-approximation factor, and, for binary strings, the 1/2-approximation factor, have been slightly improved ([HSSS19] and [RS19b], respectively). There are a few fine-grained complexity results for approximate LCS, but they only hold against deterministic algorithms, and rely on very strong assumptions [AB17, AR18, CGL+19].

30.1.1 Our Results

For simplicity, we use $\mathsf{lcs}(A, B)$ to denote the size (not the whole sequence) of the longest common subsequence for two strings A and B. Similarly, we use $\mathrm{ED}(A, B)$ to denote the edit distance and $\mathsf{lis}(A)$ for the size of the longest common subsequence. We sometimes normalize the solution by the length of the strings so that the size of the solution remains in the interval $[0, 1]$. We refer to the normalized solutions by $\|\mathsf{lcs}(A, B)\| = \mathsf{lcs}(A, B)/n$ and $\|\mathrm{ED}(A, B)\| = \mathrm{ED}(A, B)/2n$ (here both strings have equal length n), and $\|\mathsf{lis}(A)\| = \mathsf{lis}(A)/n$. In this way, $\|\mathrm{ED}(A, B)\| + \|\mathsf{lcs}(A, B)\| = 1$ (assuming both strings have equal length).

As mentioned earlier, recent developments for edit distance are based on a simple but rather useful observation. Edit distance satisfies triangle inequality, or in other words, given three strings A_1, A_2, A_3 of length n such that $\|\mathrm{ED}(A_1, A_2)\| \leq \delta$ and $\|\mathrm{ED}(A_2, A_3)\| \leq \delta$ hold, we can easily imply that $\|\mathrm{ED}(A_1, A_3)\| \leq 2\delta$. While lcs does not satisfy the triangle inequality in any meaningful way, it does, *on average*, satisfy the following birthday-paradox-like property that we call *birthday triangle inequality*.

Property 30.1.1 (birthday triangle inequality). Consider three equal-length strings A_1, A_2, and A_3 such that $\|\mathsf{lcs}(A_1, A_2)\| \geq \lambda$ and $\|\mathsf{lcs}(A_2, A_3)\| \geq \lambda$. If the common subsequences

correspond to random indices of each string, we expect that $\|\mathsf{lcs}(A_1, A_3)\| \geq \lambda^2$.

Of course, this is not necessarily the case in general. More precisely, it is easy to construct examples[4] in which $\|\mathsf{lcs}(A_1, A_2)\| = 1/2$ and $\|\mathsf{lcs}(A_2, A_3)\| = 1/2$, but $\|\mathsf{lcs}(A_1, A_3)\| = 0$. Our first main result shows that while it only holds on average, we can algorithmically replace the triangle inequality for edit distance with the birthday triangle inequality *on worst case inputs*.

Theorem 30.1.2 (Main Theorem, formally stated as Theorem 30.2.1)**.** *Given strings A, B both of length n such that $\|\operatorname{LCS}(A, B)\| = \lambda$, we can approximate the length of the LCS between the two strings within an $O(\lambda^3)$ factor in subquadratic time. The approximation factor improves to $(1-\epsilon)\lambda^2$ when $1/\lambda$ is constant.*

We remark that our algorithm is actually able to output the whole sequence of the solution, but we only focus on estimating the size of the solution for simplicity. We begin by comparing our main theorem to previous work on edit distance. In this case, $1/\lambda$ is constant w.l.o.g.[5] and therefore the approximation factor of our algorithm is $(1-\epsilon)\lambda^2$. If $\delta = \|\operatorname{ED}(A, B)\|$, then our LCS algorithm outputs a transformation from A to B using at most $2n(1-(1-\epsilon)(1-\delta)^3)$ operations. Observe that when the strings are not overly close and $\delta = \Omega(1)$ by scaling ϵ, we already recover a $(3+\epsilon')$-approximation for edit distance in truly subquadratic time. For mildly far strings, say $\delta = 0.1$, a more careful look at the expansion of $(1-\delta)^3$ reveals that we save an additive $\Theta(\delta^2)$ in the approximation factor. For example, with $\delta = 0.1$ our approximation factor for edit distance is 2.71 instead of 3.

[4] For example, $A_1 = 0^{n/2}0^{n/2}, A_2 = 0^{n/2}1^{n/2}, A_3 = 1^{n/2}1^{n/2}$.

[5] When we use our solution to approximate edit distance, we can safely assume that $\|\mathsf{lcs}(A, B)\| = \Omega(1)$ since otherwise the edit distance of the two strings is very close to $2n$.

An interesting implication of our main result is for LCS over a large alphabet Σ, where the optimum $\|\operatorname{LCS}(A,B)\|$ may be much smaller than 1. This is believed to be the hardest regime for approximation algorithms (and indeed the only one for which we have any conditional hardness of approximation results [AB17, AR18, CGL+19]). Here, we consider instances that satisfy a mild balance assumption: we assume that there is a character that appears with frequency at least $1/|\Sigma|$ in both strings[6]. Then, our main theorem implies an $O(1/|\Sigma|^{3/4})$-approximate solution in truly subquadratic time (the first improvement over the trivial $1/|\Sigma|$ approximation in this regime).

Corollary 30.1.3 (LCS, formally stated as Corollary 30.2.3)**.** *Given a pair of strings (A,B) of length n over alphabet Σ that satisfy the balance condition, we can approximate their LCS within an $O(|\Sigma|^{3/4})$ factor in truly subquadratic time.*

Next, we show that a similar result can be obtained for LIS. Perhaps coincidentally, the approximation factor of our algorithm is also $O(\lambda^3)$ which is same to LCS, but the technique is completely different. Although LIS can be solved exactly in time $O(n \log n)$, there have been several attempts to approximate the size of LIS and related problems in sublinear time [Sch61, Fre75, DGL+99, EKK+00, Fis04, ACCL07, SS10]. The best known solution is due to the work of Saks and Seshadhri [SS10] that obtains a $(1+\epsilon)$-approximate algorithm for LIS in polylogarithmic time, when the solution size is at least a constant fraction of the input size [7]. In other words, if $\|\mathsf{lis}(A)\| = \lambda$ and $1/\lambda$ is constant, their algorithm approximates

[6] Note that in every instance in each string there is a character that appears with frequency at least $1/|\Sigma|$, but in general that may not be the same character.

[7] Their algorithm obtains an additive error of δn in time $2^{\widetilde{O}(1/\delta)}$. When the solution size is bounded by λn, one needs to set $\delta < \lambda$ in order to guarantee a multiplicative factor approximation.

$\mathsf{lis}(A)$ in polylogarithmic time. However, this only works if $1/\lambda$ is constant and even if $1/\lambda$ is logarithmically large, their method fails to run in sublinear time[8]. We complement the work of Saks and Seshadhri [SS10] by presenting a result for LIS similar to our result for LCS. More precisely, we show that when $\|\mathsf{lis}(A)\| = \lambda$, an $O(\lambda^3)$ approximation of LIS can be obtained in truly sublinear time. Although our approximation factor is worse than that of [SS10], our result works for any (not necessarily constant) λ.

Theorem 30.1.4 (LIS, formally stated as Theorem 30.4.8)**.** *Given an array A of n integer numbers such that $\|\mathsf{lis}(A)\| = \lambda$. We can approximate the length of the LIS for A in sublinear time within a factor $O(\lambda^3)$.*

If one favors the running time over the approximation factor, it is possible to improve the exponent of n in the running time down to any constant $\kappa > 0$ at the expense of incurring a larger multiplicative factor to the approximation.

30.1.2 Preliminaries

In LCS or edit distance, we are given two strings A and B as input. We assume for simplicity that the two strings have equal length and refer to that by n. In LCS, the goal is to find the largest subsequence of the characters which is shared between the two strings. In edit distance, the goal is to remove as few characters as possible from the two strings such that the remainders for the two strings are the same. We use $\mathsf{lcs}(A, B)$ and $\mathrm{ED}(A, B)$ to denote the size of the longest common subsequence and the edit distance of two strings A and B.

[8] There is a term $(1/\lambda)^{1/\lambda}$ in the running time.

In LIS, the input contains an array A of n integer numbers and the goal is to find a sequence of elements of A whose values (strictly) increase as their indices increase. For LIS, we denote the solution size for an array A by $\mathsf{lis}(A)$. We also use $\mathsf{lis}^{[\alpha,\beta]}(A)$ to denote the size of the longest increasing subsequence subject to elements whose values lie in range $[\alpha, \beta]$. Longest increasing subsequence is equivalent to LCS when the inputs are two permutations of n distinct characters.

Finally, we define a notation to denote the normalized solution sizes. For LCS, we denote the normalized solution size by $\|\mathsf{lcs}(A,B)\| = \mathsf{lcs}(A,B)/\sqrt{|A||B|}$ for A and B and we use $\|\operatorname{ED}(A,B)\| = \operatorname{ED}(A,B)/(2\sqrt{|A||B|})$ for edit distance. Note that, when the two strings have equal length we have $\|\operatorname{ED}(A,B)\| + \|\mathsf{lcs}(A,B)\| = 1$. Similarly, for longest increasing subsequence, we denote by $\|\mathsf{lis}(A)\| = \mathsf{lis}(A)/|A|$ the normalized solution size. We usually refer to the size of the input array by n.

Throughout this paper, we call an algorithm $f(\lambda)$-approximation for LCS if it is able to distinguish the following two cases: i) $\|\mathsf{lcs}(A,B)\| \geq \lambda$ or ii) $\|\mathsf{lcs}(A,B)\| < \lambda f(\lambda)$. A similar definition carries over to LIS. Once an $f(\lambda)$-approximation algorithm is provided for either LCS or LIS, one can turn it into an algorithm that outputs a solution with size $f(\lambda)(1-\epsilon)\lambda n$ provided that the optimal solution has a size λn. The algorithm is not aware of the value of λ but will start with $\lambda_0 = 1$ and iteratively multiply λ_0 by $1-\epsilon$ until a solution is found.

30.1.3 Techniques Overview

Our algorithm for LCS is closely related to the recent developments for edit distance [BEG+18, CDG+18]. We begin by briefly explaining the previous ideas for approxi-

mating edit distance and then we show how we use these techniques to obtain a solution for LCS. Finally, in Section 30.1.3.2 we outline our algorithm for LIS.

30.1.3.1 Summary of Previous ED Techniques

Indeed, edit distance is hard only if the two strings are far ($\|\operatorname{ED}(A,B)\| = \delta$ and $\delta = n^{-o(1)}$) otherwise the $O(n + (n\delta)^2)$ algorithm of Landau *et al.* [LMS98] computes the solution in truly subquadratic time. The algorithm of Chakraborty *et al.* [CDG+18] for edit distance has three main steps that we briefly discuss in the following.

Step 0 (window-compatible solutions): In the first step, they construct a set of windows W_A for string A and a set of windows W_B for string B. Each window is essentially a substring of the given string. Let k denote the total number of windows of $W_A \cup W_B$. For simplicity, let all the windows have the same size d and $n \simeq O(kd)$[9]. The construction features two key properties: 1) provided that the edit distances of the windows between W_A and W_B are available, one can recover a $1+\epsilon$ approximation of edit distance in time $\widetilde{O}(n+k^2)$ via dynamic programming. 2) $k^2 \times d^2 \simeq O(n^2)$. That is, if we naively compute the edit distance of every pair of windows, the overall running time would still asymptotically be the same as that of the classic algorithm.

In order to obtain a solution for edit distance, it suffices to know the distances between the windows. However, Chakraborty *et al.* [CDG+18] show that knowing the distances between most of the window pairs is enough to obtain an approximately optimal solution for edit distance. More precisely, if the distances are not correctly approximated for at

[9]The equality holds if we assume $\delta = \Omega(1)$.

most $O(k^{2-\Omega(1)})$ pairs, we can still obtain an approximate solution for edit distance. Step 1 provides estimates for the distances of the windows which is approximately correct except for $O(k^{2-\Omega(1)})$ many pairs and Step 2 shows how this can be used to obtain a solution for edit distance. Discretization simplifies the problem substantially. For a fixed $0 \leq \delta \leq 1$, they introduce a graph G_δ where the nodes correspond to the windows and an edge between window $w_i \in W_A$ and window $w_j \in W_B$ means that $\| \operatorname{ED}(w_i, w_j)\| \leq \delta$. If we are able to construct G_δ for logarithmically different choices of δ, we can as well estimate the distances within a $1+\epsilon$ factor for the windows. Therefore the problem boils down to constructing G_δ for a fixed given δ without computing the edit distance between all pairs of windows.

Step 1 (sparsification via triangle inequality): This step is the heart of the algorithm. Suppose we choose a high-degree vertex v from G_δ and discover all its incident edges by computing its edit distance to the rest of the windows. Triangle inequality implies that every pair of windows in $N(v)$ has a distance bounded by 2δ. Therefore by losing a factor 2 in the approximation, one can put all these edges in G_δ and not compute the edit distances explicitly. Although this does save some running time, in order to make sure the running time is truly subquadratic, we need to make a similar argument for paths of length 3 and thereby lose a factor 3 in the approximation. This method sparsifies the graph and what remains is to discover the edges of a sparse graph.

Step 2 (discovering the edges of the sparse graph): Step 1 uses triangle inequality and discovers many edges between the vertices of G_δ. However, it may not discover all the edges completely. When in the remainder graph, the degrees are small (and hence the graph

is sparse) triangle inequality does not offer an improvement and thus a different approach is required. Roughly speaking, Chakraborty *et al.* [CDG+18] subsample the windows of W_A into a smaller set S and discover all pairs of windows $w_i \in S$ and $w_j \in W_B$ such that edge (i, j) is not discovered in Step 1. Next, they compute the edit distance of each pair of windows $(w_i, w_j), w_i \in W_A, w_j \in W_B$ such that there exist two nearby windows (w_a, w_b) satisfying $w_a \in S, w_b \in W_B$ and the edge between w_a and w_b was missed in Step 1. The key observation is that even though this procedure does not discover all the edges, the approximated distances lead to an approximate solution for edit distance.

30.1.3.2 LCS

Our algorithm for LCS mimics the same guideline. In addition to this, Steps 0 and 2 of our algorithm are LCS analogues of the ones used by Chakraborty *et al.* [CDG+18]. The main novelty of our algorithm is Step 1 which is a replacement for triangle inequality. Recall that unlike edit distance, triangle inequality does not hold for LCS.

Challenge 30.1.5. How can we introduce a notion similar to triangle inequality to a non-metric setting such as LCS?

We introduce the notion of birthday triangle inequality to overcome the above difficulty. Given windows w_1, w_2, and w_3 of size d such that $\|\mathsf{lcs}(w_1, w_2)\| \geq \lambda$ and $\|\mathsf{lcs}(w_2, w_3)\| \geq \lambda$ hold, what can we say about the LCS of w_1 and w_3? In general, nothing! $\|\mathsf{lcs}(w_1, w_3)\|$ could be as small as 0. However, let us add some randomness to the setting. Think of the LCS of w_1 and w_2 as a matching from the characters of w_1 to w_2 and similarly the LCS for w_2 and w_3 as another matching between characters of w_2 and w_3. Assume (for the sake of the thought experiment) that the characters of w_2 appear randomly in each matching. Since

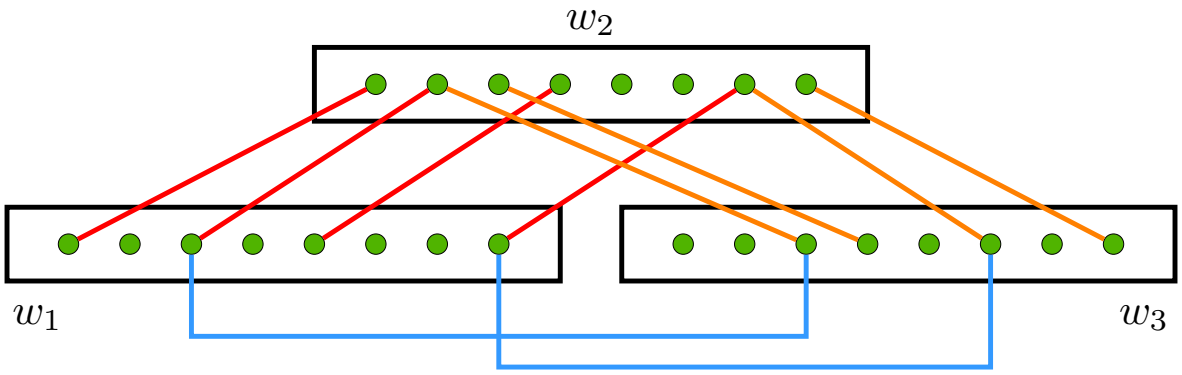

Figure 30.1: Birthday paradox for triangle inequality: let w_1, w_2, w_3 be three windows of length $d = 8$ and assume $\lambda = 1/2$. The LCS between w_1 and w_2 is $\lambda d = 4$ and the LCS between w_2 and w_3 is $\lambda d = 4$. Finally due to birthday paradox, we expect that the LCS between w_1 and w_3 is $\lambda^2 d = 2$.

$\|\mathsf{lcs}(w_1, w_2)\| \geq \lambda$, each character of w_2 appears with probability at least λ in the matching between w_1 and w_2. A similar argument implies that each character of w_2 appears with probability λ in the matching of w_2 and w_3. Thus, (assuming independence), each character of w_2 appears in both matchings with probability λ^2. This means that in expectation, there are $\lambda^2 d$ paths of length 2 between w_1 and w_3 which suggests $\|\mathsf{lcs}(w_1, w_3)\| \geq \lambda^2$ as shown in Figure 30.1. This is basically birthday paradox used for the sake of triangle inequality.

Replacing triangle inequality by birthday triangle inequality is particularly challenging since birthday triangle inequality only holds on average. In contrast, triangle inequality holds for any tuple of arbitrary strings. Most of our technical discussions is dedicated to proving that we can algorithmically use birthday triangle inequality to obtain a solution for the worst-case scenarios. The most inconvenient step of our analysis is to show that our algorithm estimates the LCS of most window pairs in the sparsification phase. While this is straightforward for edit distance, birthday triangle inequality requires a deeper analysis

of the underlying graph. In particular, we need to prove that if the undiscovered edges are too many, then birthday triangle inequality can be applied to certain neighborhoods of the graph.

There are two difficulties that we face here. On one hand, in order to apply birthday triangle inequality to a subgraph, we need to have enough structure for that subgraph to show the implication can be made. On the other hand, our assumptions cannot be too strong, otherwise such neighborhoods may not cover the edges of the graph. Therefore, the first challenge that we need to overcome is characterizing subgraphs in which birthday triangle inequality is guaranteed to be applicable. Our suggestion is the *bi-cliques* structure. Although combinatorial techniques seem unlikely to prove this, we use the Blakley-Roy inequality to show that in a large enough bi-clique, we can use birthday triangle inequality to imply a bound on the LCS of certain pairs. The second challenge is to prove that if the underlying graph is dense enough, the graph contains many bi-cliques that cover almost all the edges that we plan to discover. This is again a challenging graph theoretic problem. We leverage extremal graph theory tools such as Turan's theorem for cliques and bi-cliques to obtain this bound.

Similar to edit distance, we construct a set $W = W_A \cup W_B$ of k windows in Step 0 and aim to sparsify the edges of the lcs-graph in Step 1. Our construction ensures that $kd \simeq \Theta(n)$ and that knowing the LCS of the window pairs suffices to approximate the LCS of the two strings. For a threshold $0 \leq \lambda \leq 1$, define a matrix $\mathsf{O} : [k] \times [k] \to \{0, 1\}$ to be a matrix which identifies whether $\|\mathsf{lcs}(w_i, w_j)\| \geq \lambda$. In other words, $\mathsf{O}[i][j] = 1 \iff \|\mathsf{lcs}(w_i, w_j)\| \geq \lambda$. For an $0 < \alpha \leq 1$, we call a matrix O_α an α approximation of O if it meets the following two conditions:

$$\mathsf{O}_\alpha[i][j] = 0 \Longrightarrow \|\mathsf{lcs}(w_i, w_j)\| < \lambda \qquad \text{and} \qquad \mathsf{O}_\alpha[i][j] = 1 \Longrightarrow \|\mathsf{lcs}(w_i, w_j)\| \geq \alpha \cdot \lambda$$

Notice that O_α gives more flexibility than O for the cases that $\lambda\alpha \leq \mathsf{lcs}(w_i, w_j) < \lambda$. That is, both 0 and 1 are acceptable in these cases. Indeed an α approximation algorithm for the above problem is enough to obtain an α approximation algorithm for LCS. However, this is not necessary as Step 2 allows for incorrect approximation for up to $k^{2-\Omega(1)}$ many window pairs. Therefore, the problem of approximating LCS essentially boils down to approximating O for a given basket of windows $W = W_a \cup W_b$ and a fixed λ by allowing sufficiently small error in the output. A naive solution is to iterate over all pairs w_i and w_j and compute $\mathsf{lcs}(w_i, w_j)$ in time $O(d^2)$ and determine O accordingly. However, this amounts to a total running time of $O(k^2d^2)$ which is quadratic and not desirable. In order to save time, we need to compute the LCS of fewer than k^2 pairs of windows. To make this possible, we allow our algorithm to miss up to $O(k^{2-\Omega(1)})$ edges of the graph. Step 2 ensures that this does not hurt the approximation factor significantly.

We construct a graph from the windows wherein each vertex corresponds to a window and each edge identifies a pair with a large LCS (in terms of λ). Let us call this graph the lcs-graph and denote it by G_λ. The goal is to detect the edges of the graph by allowing false-positive. As we discussed earlier, the hard instances of the problem are the cases where the lcs-graph is dense for which we need a sparsifier. Roughly speaking, in our sparsification technique, our algorithm constructs another graph $\widehat{\mathsf{G}}_\lambda$ such that $\widehat{\mathsf{G}}_\lambda$ is valid in the sense that the edges of $\widehat{\mathsf{G}}_\lambda$ correspond to pairs of windows with large enough LCS. In addition to this, our algorithm guarantees that after the removal of the edges of $\widehat{\mathsf{G}}_\lambda$ from G_λ the remainder is

sparse. In other words, $|E(\mathsf{G}_\lambda) \setminus E(\widehat{\mathsf{G}}_\lambda)| = O(|V(\mathsf{G}_\lambda)|^{2-\Omega(1)})$. Of course, if the overall running time of the sparsification phase is truly subquadratic, the error of undiscovered edges can be addressed by the techniques of [CDG+18] in Step 2.

Below, we bring a formal definition for sparsification.

sparsification
input: Windows $w_1, w_2, \ldots, w_k$, parameters λ, and α.
solution: A matrix $\widehat{\mathsf{O}}_\alpha \in \{0,1\}^{k \times k}$ such that:

- $\widehat{\mathsf{O}}_\alpha[i][j] = 1 \implies \|\mathsf{lcs}(w_i, w_j)\| \geq \alpha \cdot \lambda$
- $\left|\left\{(i,j) \mid \|\mathsf{lcs}(w_i, w_j)\| \geq \lambda \text{ and } \widehat{\mathsf{O}}_\alpha[i][j] = 0\right\}\right| = k^{2-\Omega(1)}$

We present two sparsification techniques for LCS. The first one (Section 30.3.1), has an approximation factor of $(1-\epsilon) \cdot \lambda^2$. In Section 30.3.2 we present another sparsification technique that has a worse approximation factor $O(\lambda^3)$ but leaves fewer edges behind. Although the second sparsification technique has a worse approximation factor, it has the advantage that the number of edges that remain in the sparse graph is truly subquadratic regardless of the value of λ and therefore it extends our solution to the case that $\lambda = o(1)$ (see Section 30.3.2 for a detailed discussion).

Let us note one last algorithmic challenge to keep in mind before we begin to describe our sparsification techniques. For edit distance, if window pairs (w_1, w_2) and (w_2, w_3) are close, we are *guaranteed* that w_1 and w_3 are also close; for longest common subsequence, we will argue that (w_1, w_3) are *likely* to be have a long LCS (for a "random" choice of (w_1, w_3)). Nonetheless, in order to add (w_1, w_3) as an edge to our graph we have to *verify* that their

LCS is indeed long. If we were to verify an edge naively, we would need as much time as computing the LCS between (w_1, w_3) from scratch!

Sparsification 1, $(1-\epsilon)\lambda^2$-approximation: Similar to edit distance, applying birthday triangle inequality to paths of length 2 for LCS does not improve the running time significantly. Therefore, we need to use birthday triangle inequality for paths of length 3. To this end, we define the notion of constructive tuples as follows: a tuple $\langle w_i, w_a, w_b, w_j \rangle$ is an (ϵ, λ)-constructive tuple, if we have $\|\mathsf{lcs}(w_i, w_a)\| \geq \lambda$, $\|\mathsf{lcs}(w_i, w_j)\| \geq \lambda$, $\|\mathsf{lcs}(w_b, w_j)\| \geq \lambda$ and by taking the intersection of the three LCS matchings, we are able to imply $\|\mathsf{lcs}(w_a, w_b)\| \geq (1-\epsilon)\lambda^3$ (see Figure 30.2 for an example). Taking the intersection of the matchings can be done in linear time which is faster than computing the LCS.

Our sparsification technique here is simple but the analysis is very intricate. We subsample a set S of windows and compute the LCS of every window in S and all other windows. We set $|S| = k^\gamma \log k$, where $\gamma \in (0, 1)$. At this point, for some pairs, we already know their LCS. However, if neither w_i nor w_j is in S, we do not know if $\|\mathsf{lcs}(w_i, w_j)\| \geq \lambda$ or not. Therefore, for such pairs, we try to find windows $w_a, w_b \in S$ such that $\langle w_i, w_a, w_b, w_j \rangle$ is constructive. If such a constructive tuple is found for a pair of windows, then we conclude that their normalized LCS is at least $(1-\epsilon)\lambda^3$.

All that remains is to argue that this method discovers almost all the edges of the lcs-graph G_λ and the number of undiscovered edges is $k^{2-\Omega(1)}$. This is the most difficult part of the analysis. We note that proving the existence of **only one** constructive tuple is already non-trivial **even when G_λ is complete**. However, our goal is to show almost all the edges are discovered via constructive tuples when G_λ is dense (and of course not necessarily

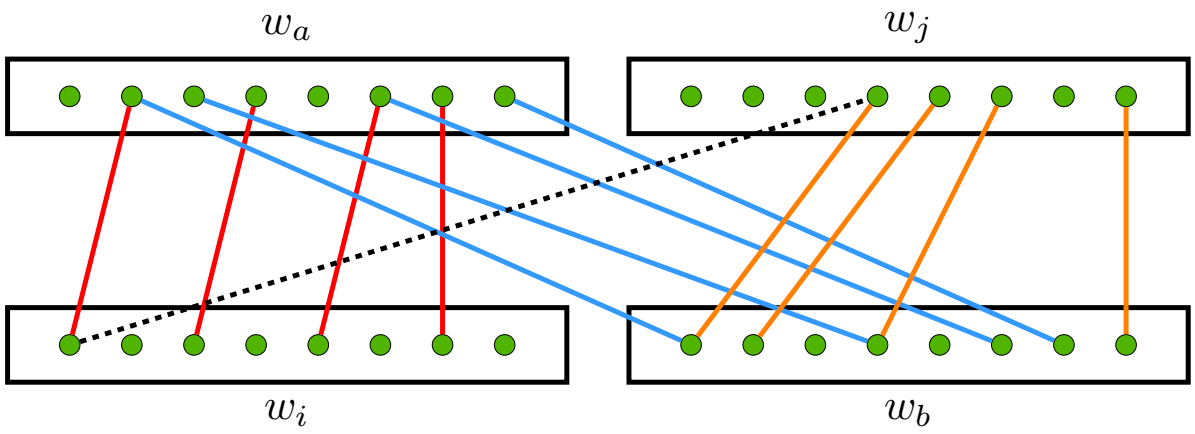

Figure 30.2: Let w_i, w_a, w_b and w_j denote four windows and each of them has length $d = 8$. This figure shows how the intersection of the edges of three windows are taken in order to construct a solution for the LCS of w_i and w_j. If the size of the intersection is large, then such a tuple is called constructive. The solid lines represent LCS between two strings, and the dashed line represents the intersection of the three LCSs.

complete).

Define a pair of windows w_i and w_j to be *well-connected*, if there are at least $k^{2-\gamma}$ different (w_a, w_b) pairs such that $\langle w_i, w_a, w_b, w_j \rangle$ is (ϵ, λ)-constructive. Since each window appears in S with probability $k^{\gamma-1} \log k$, for each well-connected pair we find one constructive tuple via our algorithm with high probablity. Therefore, we need to prove that the total number of pairs (w_i, w_j) such that (w_i, w_j) is not well-connected but $\|\mathsf{lcs}(w_i, w_j)\| \geq \lambda$ is subquadratic. Let us put these edges in a new graph NG_λ whose vertices are all the windows. We first leverage the Blakley-Roy inequality and a double counting technique to prove that if NG_λ has a large complete bipartite subgraph, then there is one constructive tuple which includes only the vertices of this subgraph (Lemma 30.3.2). Next, we apply the Turan's theorem to show that if NG_λ is dense, then it has a lot of large complete bipartite subgraphs. Finally, we use a probabilistic method to conclude that NG_λ cannot be too dense otherwise

there are a lot of constructive tuples in the graph which implies that at least one edge (w_i, w_j) in NG_λ is well-connected. This is not possible since all the well-connected pairs are detected in our sparsification algorithm with high probability.

The above argument proves that if we sparsify our graph using our sparsification algorithm, the remainder graph would have a subquadratic number of edges. Therefore after plugging Step 2 into the algorithm, the running time remains subquadratic. However, since Turan theorem gives us a weak bound, the running time of the algorithm using this sparsification is $O(n^{2-\Omega(\lambda)})$ and is only truly subquadratic when $1/\lambda$ is constant.

The above method also gives a nice insight into computing edit distance. As we show in Section 30.3, if our lcs-graph or similarly ED-graph is very dense, it contains bipartite complete subgraphs that lead to strong implications. For LCS, we obtain a bound of $(1-\epsilon)\lambda^2$ for the approximation factor of the sparsifier. For edit distance, this may lead to an approximation factor better than 3. In particular, if one gives a positive answer to Question 30.1.6 for some α, this technique improves the approximation factor of estimating edit distance in subquadratic time to $2+\alpha+\epsilon$. The authors are not aware of any counter-example for the question even when $\alpha = 0$ and it is quite possible that this technique improves the approximation factor for edit distance down to $2+\epsilon$.

Question 30.1.6. *Let X and Y be two sets of strings of length n such that for each string $A \in X$ and $B \in Y$ we have $\|\operatorname{ED}(A,B)\| \leq \delta$. If $1/\delta$ is constant and the sizes of X and Y are large enough constants (much larger than $1/\delta$) can we imply that there exist two strings in X or two strings in Y whose normalized distance is bounded by $(1+\alpha)\delta$?*

We remark that birthday triangle inequality proves Question 30.1.6 for $\alpha = 1 - O(\delta)$

even when $|X| = 1$. While we do not provide a formal proof, we believe that this already gives a $3 - o(1)$ approximation algorithm for edit distance in truly subquadratic time which slightly breaks the $3 + \epsilon$ barrier suggested in previous work [BEG+18, CDG+18].

Sparsification 2, $O(\lambda^3)$-approximation: In Section 30.3.1, we present another sparsification method that although gives us a slightly worse approximation factor $O(\lambda^3)$ it always leaves a truly subquadratic number of edges behind and therefore the running time of the algorithm would be truly subquadratic regardless of the parameter λ. This sparsification is based on a novel data structure.

Let $\mathsf{opt}_{i,a}$ denote the longest common subsequence of w_i and w_a (with some fixed tie-breaking rule, e.g. lexicographically first). Define $\mathsf{lcs}_{w_a}(w_i, w_j)$ to be the size of the longest common subsequence between $\mathsf{opt}_{i,a}$ and w_j. Notice that this definition is no longer symmetric. Let $\|\mathsf{lcs}_{w_a}(w_i, w_j)\|$ denote the relative value, i.e., $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| = \mathsf{lcs}_{w_a}(w_i, w_j)/\sqrt{|w_i| \cdot |w_j|}$. The first ingredient of the algorithm is a data-structure, namely $\mathsf{lcs\text{-}cmp}$. After a preprocess of time $O(|w_a| \sum_{i \in S} |w_i|)$, $\mathsf{lcs\text{-}cmp}$ is able to answer queries of the following type in time $O(|w_i| + |w_j|)$:

- "for a $0 \leq \widetilde{\lambda} \leq 1$ either certify that $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| \geq \Omega(\widetilde{\lambda}^2)$ or report that $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| < O(\widetilde{\lambda})$".

In our sparsification, we repeat the following procedure k^γ times, where $\gamma \in (0, 1)$. We sample a window w_a uniformly at random and construct $\mathsf{lcs\text{-}cmp}(w_a, S)$ for $S = \{w_i | i \neq a \text{ and } |w_i| \geq |w_a|\}$. After the preprocessing step, we make a query for every pair of windows (w_i, w_j) such that $w_i, w_j \in S$ and determine if $\mathsf{lcs}_{w_a}(w_i, w_j)$ is at least $\Omega(\lambda^4)$ or upper bounded

by $O(\lambda^2)$ (here $\widetilde{\lambda} = \lambda^2$). If their LCS is at least $\Omega(\lambda^4)$ we report this pair as an edge in our lcs-graph. Finally, we use the Turan theorem to prove that the number of remaining edges in our graph is small.

To be more precise, we first construct a graph NG_λ that reflects the edges that are not detected via our sparsification. We give directions to the edges based on the length of the windows. If NG_λ is dense enough, then there is one vertex v in NG_λ with a large enough outgoing degree. We use the neighbors of v to construct another graph NF_λ with vertex set $N(v)$. An edge exists in NF_λ if $\max\{\|\mathsf{lcs}_{w_v(w_i,w_j)}\|, \|\mathsf{lcs}_{w_v(w_j,w_i)}\|\} \geq \Omega(\lambda^2)$. Edges of NF_λ are directed the same way as NG_λ. We prove that NF_λ has no large independent set. In other words, if we select a large enough set of vertices in NF_λ, then there is at least one edges between them. Next, we apply the Turan theorem to prove that NF_λ is dense. Finally, we imply that since NF_λ is dense, there is one vertex u in the neighbors of v such that there are a lot of 2-paths between v and u. This implies that the edge (u, v) should have been detected in our sparsification and therefore must not exist in NG_λ. This contradiction implies that NG_λ is sparse in the first place.

30.1.3.3 LIS

In this section, we present our result for longest increasing subsequence. More precisely, we show that when the solution size is lower bounded by $n\lambda$ ($\lambda \in [0, 1]$), one can approximate the solution within a factor $O(\lambda^3)$ in time $\widetilde{O}(\sqrt{n}/\lambda^7)$. This married with a simple sampling algorithm for the cases that $\lambda < n^{-\Omega(1)}$, provides an $O(\lambda^3)$-approximate algorithm with running time of $\widetilde{O}(n^{0.85})$ (without further dependence on λ). We further extend this result to reduce the running time to $\widetilde{O}(n^\kappa \operatorname{poly}(1/\lambda))$ for any $\kappa > 0$ by imposing

a multiplicative factor of poly$(1/\lambda)$ to the approximation.

Our algorithm heavily relies on sampling random elements of the array for which longest increasing subsequence is desired. Denote the input sequence by $A = \langle a_1, a_2, \ldots, a_n \rangle$. A naive approach to approximate the solution is to randomly subsample the elements of A to obtain a smaller array B and then compute the longest increasing subsequence of B to estimate the solution size for A. Let us first show why this approach alone fails to provide a decent approximation factor. First, consider an array $A = \langle 1, 2, \ldots, n \rangle$ which is strictly increasing. Based on A, we construct two inputs A' and A'' in the following way:

- A' is exactly equal to A except that a p fraction of the elements in A' are replaced by 0.
- A'' is exactly equal to A except that every block of length $\sqrt{n}$ is reversed in A''. In other words, $A'' = \langle \sqrt{n}, \sqrt{n}-1, \sqrt{n}-2, \ldots, 1, 2\sqrt{n}, 2\sqrt{n}-1, \ldots, \sqrt{n}+1, \ldots, n, n-1, n-2, \ldots, n-\sqrt{n}+1 \rangle$.

We subsample the two arrays A' and A'' with a rate of $1/\sqrt{n}$ to obtain two smaller arrays B' and B'' of size roughly $O(\sqrt{n})$. It is easy to prove that $\mathsf{lis}(B') = \Omega(\sqrt{n})$ and $\mathsf{lis}(B'') = \Omega(\sqrt{n})$ both hold even though $\mathsf{lis}(A') = \Omega(n)$ but $\mathsf{lis}(A'') = O(\sqrt{n})$. By setting $p = 1/e$ we can also make sure that $\mathsf{lis}(B')$ and $\mathsf{lis}(B'')$ are within a small multiplicative range even though the gap between $\mathsf{lis}(A')$ and $\mathsf{lis}(A'')$ is substantial.

The above observation shows that the problem is very elusive when random sampling is involved. We bring a remedy to this issue in the following. Divide the input array into $\sqrt{n}$ subarrays of size $\sqrt{n}$. We denote the subarrays by $\mathsf{sa}_1, \mathsf{sa}_2, \ldots, \mathsf{sa}_{\sqrt{n}}$ and fix an

optimal solution opt for the longest increasing subsequence of A. Define $\mathsf{sm}(\mathsf{sa}_i)$ to be the smallest number in sa_i that contributes to opt and $\mathsf{lg}(\mathsf{sa}_i)$ to be the largest number in sa_i that contributes to opt. Moreover, define $\mathsf{lis}^{[\ell,r]}$ to be the longest increasing subsequence of an array subject to the elements whose values lie within the interval $[\ell, r]$. This immediately implies

$$\mathsf{lis}(A) = \sum_{i=1}^{\sqrt{n}} \mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i).$$

Another observation that we make here is that since we assume $\|\mathsf{lis}(A)\| \geq \lambda$ and the size of each subarray is bounded by $\sqrt{n}$, then we have

$$\frac{\mathsf{lis}(A)}{\max_i \mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i)} \geq \sqrt{n}\lambda$$

which essentially means that in order to approximate $\mathsf{lis}(A)$ it suffices to compute $\mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i)$ for $\widetilde{O}(1/\lambda)$ many randomly sampled subarrays. This is quite helpful since this shows that we only need to sample $\widetilde{O}(1/\lambda)$ many subarrays and solve the problem for them. However, we do not know the values of $\mathsf{sm}(\mathsf{sa}_i)$ and $\mathsf{lg}(\mathsf{sa}_i)$ in advance. Therefore, the main challenge is to predict the values of $\mathsf{sm}(\mathsf{sa}_i)$ and $\mathsf{lg}(\mathsf{sa}_i)$ before we sample the subarrays.

Indeed, one needs to read the entire array to correctly compute $\mathsf{sm}(\mathsf{sa}_i)$ and $\mathsf{lg}(\mathsf{sa}_i)$ for each of the subarrays. However, we devise a method to approximately guess these values without losing too much in the size of the solution. Roughly speaking, we show that if we sample $k = O(1/(\lambda\epsilon))$ different elements from a subarray sa_i for some constant ϵ and denote

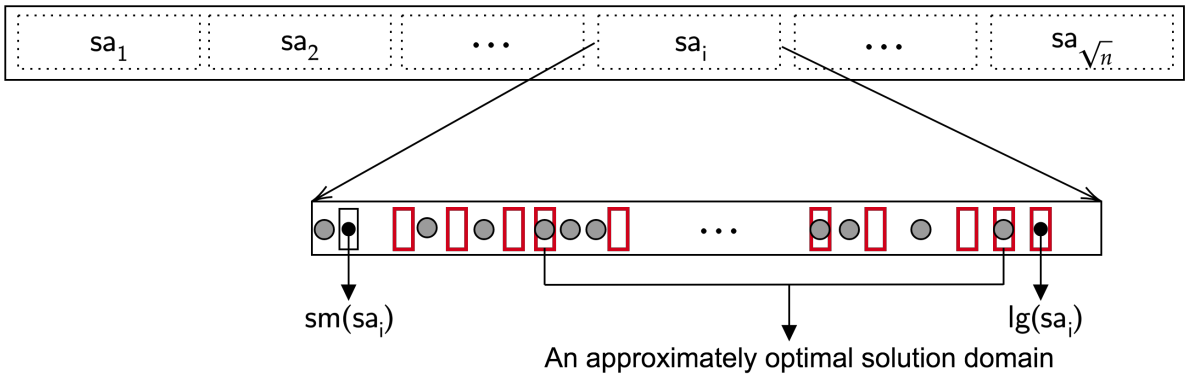

Figure 30.3: Red rectangles show the elements of sa_i that contribute to $\mathsf{lis}(A)$ and gray circles show the elements of sa that are sampled via our algorithm.

them by $a_{j_1}, a_{j_2}, \ldots, a_{j_k}$, then for at least one pair (α, β), $[a_{j_\alpha}, a_{j_\beta}]$ is approximately close to $[\mathsf{sm}(\mathsf{sa}_i), \mathsf{lg}(\mathsf{sa}_i)]$ up to a $(1-\epsilon)$ factor.

The above argument provides $O((1/(\lambda\epsilon))^2)$ candidate domain intervals for each sa_i. However, this does not provide a solution since we do not know which candidate domain interval approximates $[\mathsf{sm}(\mathsf{sa}_i), \mathsf{lg}(\mathsf{sa}_i)]$ for each sa_i. Of course, if we were to randomly choose one candidate interval for every subarray, we would make a correct guess for at least $O(\sqrt{n}(\lambda\epsilon)^2)$ subarrays which provides an approximation guarantee of $O(\lambda^2)$ for our algorithm. However, our assignments have to be monotone too. More precisely, let $[\widetilde{\mathsf{sm}}(\mathsf{sa}_i), \widetilde{\mathsf{lg}}(\mathsf{sa}_i)]$ be the guesses that our algorithm makes, then we should have

$$\widetilde{\mathsf{sm}}(\mathsf{sa}_1) \leq \widetilde{\mathsf{lg}}(\mathsf{sa}_1) \leq \widetilde{\mathsf{sm}}(\mathsf{sa}_2) \leq \widetilde{\mathsf{lg}}(\mathsf{sa}_2) \leq \ldots \leq \widetilde{\mathsf{sm}}(\mathsf{sa}_{\sqrt{n}}) \leq \widetilde{\mathsf{lg}}(\mathsf{sa}_{\sqrt{n}}).$$

Random sampling does not guarantee that the sampled intervals are monotone. To address this issue, we introduce the notion of *pseudo-solutions*. A pseudo-solution is an as-

signment of monotone intervals to subarrays in order to approximate $\mathsf{sm}(\mathsf{sa}_i)$ and $\mathsf{lg}(\mathsf{sa}_i)$. The *quality* of a pseudo solution with intervals $[\ell_1, r_1], [\ell_2, r_2], \ldots, [\ell_{\sqrt{n}}, r_{\sqrt{n}}]$ is equal to $\sum_i \mathsf{lis}^{[\ell_i, r_i]}(\mathsf{sa}_i)$. For a fixed pseudo-solution, this can be easily approximated via random sampling. Thus, our goal is to construct a pseudo-solution whose quality is at least an $O(\lambda^3)$ approximation of the size of the optimal solution. To this end, we present a greedy method in Section 30.4.2 to construct the desired pseudo-solution.

Finally, in Section 30.4.4, we show how the above ideas can be generalized to improve the running time down to $\widetilde{O}(n^{\kappa}\,\mathrm{poly}(1/\lambda))$ for any arbitrarily small $\kappa > 0$ by imposing a factor $\mathrm{poly}(1/\lambda)$ to the approximation guarantee.

30.2 Organization of the Paper

Our algorithm for LCS is explained in Section 30.6 (Step 0), Section 30.3 (Step 1), and Section 30.7 (Step 2). Since Steps 0 and 2 follow from previous work, we only bring Step 1 in the main body of the paper and defer the rest to the appendices.

In both our results for LCS and LIS, we assume that the goal is to find approximate solutions, provided that the solution size is at least $\lambda_0 n$. After the algorithms terminate, if the output is smaller than what we expect, we realize that the solution is smaller than $\lambda_0 n$. Therefore, we begin by setting $\lambda_0 = 1$ and iteratively multiply λ_0 by a $1 - \epsilon$ factor until we obtain a solution. This only adds a multiplicative factor of $\log 1/\lambda$ to the running time and a multiplicative factor of $1 - \epsilon$ to the approximation. Since we present two different sparsification techniques, we obtain two theorems: one is Theorem 30.2.1 and the other is Theorem 30.2.2.

Theorem 30.2.1. *Given strings A, B of length $|A| = |B| = n$ with $\|\operatorname{LCS}(A, B)\| = \lambda$, we can approximate the length of the LCS between the two strings within a factor $O(\lambda^3)$ in time $\widetilde{O}(n^{39/20})$.*

Proof. If $\lambda \leq n^{-20}$ we run the classic $O(n^2\lambda)$ time algorithm and get an exact solution in the desired time. Otherwise, we begin by setting $\lambda_0 = 1$ and iteratively multiply λ_0 by a factor $1-\epsilon$ until a solution is found with size at least $\Omega(\lambda^3)n$. This adds an overhead of $O(\log 1/\lambda)$ to the running time. By Choosing $d = \sqrt{n}$ we can bound the total running time of Steps 0, 1, and 2 by $\widetilde{O}(n^{13/10}\lambda^{-13}) \leq \widetilde{O}(n^{39/20})$. □

Theorem 30.2.2. *Given strings A, B of length $|A| = |B| = n$ with $\|\operatorname{LCS}(A, B)\| = \lambda$, we can approximate the length of the LCS between the two strings within a factor $(1 - \epsilon)\lambda^2$ in*

$n^{2-\Omega(\epsilon\lambda)}$ *time for any* $\epsilon > 0$.

Proof. The proof is identical to Theorem 30.2.1, we omit the details here. □

As an immediate corollary of Theorem 30.2.1, we present an algorithm that beats the $1/|\Sigma|$ approximation factor in truly subquadratic time, when the strings are balanced.

Corollary 30.2.3. *Given a pair of strings* (A, B) *of length* n *over alphabet* Σ *that satisfy the balance condition, we can approximate their* LCS *within an* $O(|\Sigma|^{3/4})$ *factor in time* $O(n^{39/20})$.

Proof. Since A and B are balanced, there is a character $\sigma \in \Sigma$ that appears at least $n/|\Sigma|$ times in both strings. Indeed, finding a solution of size $n/|\Sigma|$ by restricting our attention to only character σ can be done in time $O(n)$. If $\mathsf{lcs}(A, B) \leq n/|\Sigma|^{1/4}$ this already gives us an $O(|\Sigma|^{3/4})$ approximate solution. Otherwise, $\|\mathsf{lcs}(A, B)\| > 1/|\Sigma|^{1/4}$ and the approximation factor of our $O(\lambda^3)$-approximation algorithm would be bounded by $O(|\Sigma|^{3/4})$. □

Finally, we bring our results for LIS in Section 30.4. We show that

Theorem 30.2.4. *Given a length-*n *sequence* A *with* $\mathsf{lis}(A) = n\lambda$. *We can approximate the length of the* LIS *within a factor of* $O(\lambda^3)$ *in time* $\widetilde{O}(n^{17/20})$.

Proof. If $\lambda < n^{-1/20}$ we sample the array with a rate of $n^{-3/20}$ and compute the LIS for the sampled array. The running time of the algorithm is $\widetilde{O}(n^{17/20})$. The approximation factor is $O(n^{-3/20}) \geq O(\lambda^3)$. Otherwise, by Theorem 30.4.8, we estimate the size of LIS up to an $O(\lambda^3)$ approximation factor in time $\widetilde{O}(\lambda^{-7}\sqrt{n}) \leq \widetilde{O}(n^{17/20})$. □

30.3 LCS Step 1: Sparsification via Birthday Triangle Inequality

Recall that we are given two sets of windows W_A and W_B for the strings and our goal is to approximate the LCS of every pair of windows between W_A and W_B. For simplicity, we put all the windows in the same basket $W = W_1 \cup W_2$ and denote the windows by $w_1, w_2, \ldots, w_k$ where k is the total number of windows. Since the windows have different lengths, we define $\mathsf{w}_{\mathsf{max}} = \max_{i\in[k]} |w_i|$ to be the maximum length of the windows. Similarly, we also define $\mathsf{w}_{\mathsf{min}} = \min_{i\in[k]} |w_i|$ to be the minimum length of the windows. Let $\mathsf{w}_{\mathsf{gap}} = \mathsf{w}_{\mathsf{max}}/\mathsf{w}_{\mathsf{min}}$. Let $\mathsf{w}_{\mathsf{layers}}$ denote the number of different window sizes. Notations $\mathsf{w}_{\mathsf{gap}}$ and $\mathsf{w}_{\mathsf{layers}}$ will be used in the later analysis.

In order to approximate the LCS's we fix a $\lambda \in \{\epsilon\lambda_0, (1+\epsilon)\epsilon\lambda_0, (1+\epsilon)^2\epsilon\lambda_0, \ldots, 1\}$ and sparsify graph G_λ. In Section 30.3.1, we present a sparsification algorithm (Algorithm 30.1) which provides λ^2-approximation when λ is constant. The formal guarantee of the algorithm is provided in Theorem 30.3.6. In Section 30.3.2, we present a sparsification which provides $O(\lambda^3)$-approximation for any (potentially super-constant) λ.

30.3.1 Sparsification for O_{λ^2}

In our solution, we fix an arbitrary LCS for every pair of windows and refer to that as $\mathsf{opt}_{i,j}$ for two windows w_i and w_j. Note that we do not explicitly compute $\mathsf{opt}_{i,j}$ in our algorithm. Let us for simplicity, think of each $\mathsf{opt}_{i,j}$ as a matching between the characters of the two windows. Also, denote by $\left(\mathsf{opt}_{i,a} \cap \mathsf{opt}_{a,b} \cap \mathsf{opt}_{b,j}\right)$ a solution which is constructed for windows w_i and w_j by taking the intersection of $\left(\mathsf{opt}_{i,a} \cap \mathsf{opt}_{a,b} \cap \mathsf{opt}_{b,j}\right)$. More precisely,

we have

$$(x, y) \in \left(\mathsf{opt}_{i,a} \cap \mathsf{opt}_{a,b} \cap \mathsf{opt}_{b,j}\right) \Longleftrightarrow \exists \alpha, \beta \text{ such that}$$
$$(x, \alpha) \in \mathsf{opt}_{i,a} \text{ and}$$
$$(\alpha, \beta) \in \mathsf{opt}_{a,b} \text{ and}$$
$$(\beta, y) \in \mathsf{opt}_{b,j}.$$

Let $\left\|\left(\mathsf{opt}_{i,a} \cap \mathsf{opt}_{a,b} \cap \mathsf{opt}_{b,j}\right)\right\| = \frac{\left|\left(\mathsf{opt}_{i,a} \cap \mathsf{opt}_{a,b} \cap \mathsf{opt}_{b,j}\right)\right|}{\sqrt{|w_i||w_j|}}$.

Definition 30.3.1 ((ϵ, λ)-constructive)**.** We call a tuple $\langle w_i, w_a, w_b, w_j \rangle$ $(w_i \neq w_a \neq w_b \neq w_j)$ a *constructive* tuple, if $\left\|\left(\mathsf{opt}_{i,a} \cap \mathsf{opt}_{a,b} \cap \mathsf{opt}_{b,j}\right)\right\| \geq (1 - \epsilon)\lambda^3$.

The advantage of a constructive tuple is that if $\mathsf{opt}_{i,a}, \mathsf{opt}_{a,b}$, and $\mathsf{opt}_{b,j}$ are provided, one can construct a desirable solution for $\mathsf{opt}_{i,j}$ in linear time by taking the intersection of the given matchings. Our algorithm is actually based on the above observation. We bring our algorithm in the following:

We parameterize our algorithm by a value $0 < \gamma < 1$ to be set later. One may optimize the runtime of the algorithm by setting the value of γ in terms of the number of windows and the length of the windows. We first sample a set S of $O(k^\gamma \log k)$ windows. Next, we compute $\mathsf{opt}_{i,j}$ of every window $w_i \in S$ and every other window w_j (not necessarily in S). Finally, we find all the constructive tuples $\langle w_i, w_a, w_b, w_j \rangle$ such that $w_a, w_b \in S$ and update $\widehat{\mathsf{O}}_{\lambda^2}$ accordingly. This is shown in Algorithm 30.1.

The running time of our algorithm is equal to $O(k|S|\mathsf{w}_{\mathsf{max}}^2 + k^2|S|^2\mathsf{w}_{\mathsf{max}})$. The rest of this section is dedicated to proving that what remains in the lcs-graph is sparse.

We first introduce the notion of well-connected pairs.

    end for
  end for
  return $\widehat{\mathsf{O}}_{\lambda^2}$
end procedure

Definition 30.3.2 (well-connected pair)**.** We say a pair of windows (w_i, w_j) is *well-connected*, if there are at least $k^{2-\gamma}$ pairs of windows (w_a, w_b) such that $\langle w_i, w_a, w_b, w_j \rangle$ is (ϵ, λ)-constructive.

It follows from the definition that well-connected pairs are detected in our algorithm with high probability.

Lemma 30.3.1. *Let $\widehat{\mathsf{O}}_{\lambda^2} \in \{0,1\}^{k\times k}$ denote the output of Algorithm 30.1. With probability at least $1 - 1/\operatorname{poly}(k)$, for all $(i,j) \in [k] \times [k]$ such that (w_i, w_j) is a well-connected pair (Definition 30.3.2), we have $\widehat{\mathsf{O}}_{\lambda^2}[i][j] = 1$.*

Proof. We consider a fixed (i,j) such that pair (w_i, w_j) is well-connected. Let

$$Q_{i,j} = \left\{ (a,b) \;\middle|\; \left\| \mathsf{opt}_{i,a} \cap \mathsf{opt}_{a,b} \cap \mathsf{opt}_{b,j} \right\| \geq (1-\epsilon)\lambda^3 \right\}.$$

Conceptually, we divide the process of sampling S into two phases: we sample $20k^\gamma \log k$ windows in the first phase, and then we sample another $20k^\gamma \log k$ windows in the second phase.

For each $a \in [k]$, let $Q_{i,j,a} = \{b : (a,b) \in Q_{i,j}\}$. Since $\sum_{a\in[k]} |Q_{i,j,a}| = |Q_{i,j}| \geq k^{2-\gamma}$, there are at least

$$\frac{k^{2-\gamma} - k \cdot k^{1-\gamma}/2}{k} = \frac{k^{1-\gamma}}{2}$$

different number a's in $[k]$ such that $|Q_{i,j,a}| \geq \frac{k^{1-\gamma}}{2}$. Hence, in the first phase, there is a sampled number q such that $|Q_{i,j,q}| \geq k^{1-\gamma}/2$ with probability at least

$$1 - \left(1 - \frac{k^{1-\gamma}/2}{k}\right)^{20k^\gamma \log k} < \frac{1}{k^5}.$$

We fix such a q. In the second phase, there is a sampled number r such that $r \in Q_{i,j,q}$ with probability at least

$$1 - \left(1 - \frac{k^{1-\gamma}/2}{k}\right)^{20k^\gamma \log k} < \frac{1}{k^5}.$$

The lemma is obtained by a union bound on all the well-connected pairs (w_i, w_j). □

In what follows, we bound $|\{(i,j) \mid \|\mathsf{lcs}(w_i, w_j)\| \geq \lambda \text{ and } \widehat{\mathsf{O}}_{\lambda^2}[i][j] = 0\}|$. In other words, we prove an upper bound on the number of edges that remain in the graph.

Definition 30.3.3 (NG_λ)**.** Define a graph NG_λ with k vertices and the following edges:

$$E(\mathsf{NG}_\lambda) = \left\{ (i,j) \;\middle|\; \|\mathsf{lcs}(w_i, w_j)\| \geq \lambda \quad \text{and} \quad \widehat{\mathsf{O}}_{\lambda^2}[i][j] = 0 \right\}.$$

We first prove that every $K_{\Omega(\mathsf{w_{gap}}/(\epsilon\lambda^3)),\Omega(\mathsf{w_{gap}}/(\epsilon\lambda^3))}$ subgraph of NG_λ corresponds to at least one constructive tuple.

Lemma 30.3.2. *Let X and Y be two sets of windows such that for every $w_i \in X$ and $w_j \in Y$ there is an (i,j) edge in $E(\mathsf{NG}_\lambda)$, for every $w_i, w_{i'} \in X$, $|w_i| = |w_{i'}|$ and for every $w_j, w_{j'} \in Y$, $|w_j| = |w_{j'}|$. If $|X| \geq \Omega(\mathsf{w_{gap}}/(\epsilon\lambda^3))$ and $|Y| \geq \Omega(\mathsf{w_{gap}}/(\epsilon\lambda^3))$, then there exist $w_i, w_a, w_b, w_j \in X \cup Y$ such that $\langle w_i, w_a, w_b, w_j \rangle$ is (ϵ, λ)-constructive, i.e.,*

$$\left\| \mathsf{opt}_{i,a} \cap \mathsf{opt}_{a,b} \cap \mathsf{opt}_{b,j} \right\| \geq (1-\epsilon)\lambda^3.$$

Proof. By assumption, we know that $|X|, |Y| \geq \Omega(\mathsf{w_{gap}}/(\epsilon\lambda^3))$. Let t_1 denote the window size for each window in X, and t_2 denote the window size for each window in Y.

We carefully select $X' \subseteq X$ and $Y' \subseteq Y$ such that

1. $|X'| \geq \Omega(1/(\epsilon\lambda^3))$.
2. $|Y'| \geq \Omega(1/(\epsilon\lambda^3))$.
3. $|X'|t_1 = (1 \pm O(\epsilon))|Y'|t_2$.

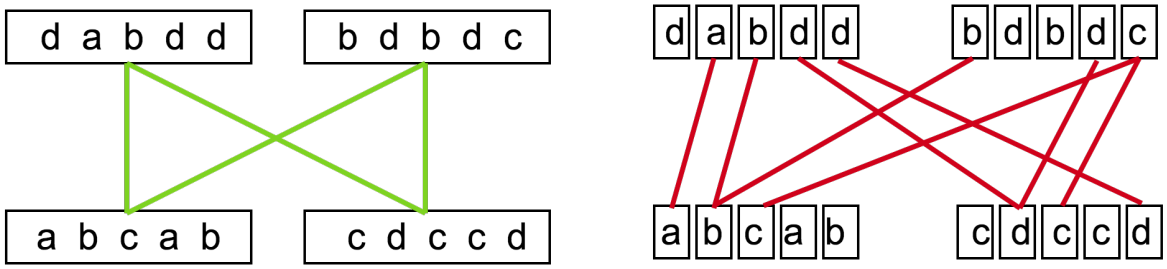

Figure 30.4: The graph on the left is an example of the string-based graph and the graph on the right is an example of the character-based graph.

To do this, if $|X|t_1 > (1 + O(\epsilon))|Y|t_2$, then we set $Y' = Y$ and select X' as an arbitrary subset of X with size $\left\lceil \frac{|Y|t_2}{t_1} \right\rceil$. if $|X|t_1 < (1 - O(\epsilon))|Y|t_2$, then we set $X' = X$ and select Y' an arbitrary subset of Y with size $\left\lceil \frac{|X|t_1}{t_2} \right\rceil$.

We define a window-based (bipartite) graph $G_W = (V_W, E_W)$ to be the subgraph of δ on $V_W = X' \cup Y'$ removing all the edges within X' and all the edges within Y'. Let $l_1 = |X'|$ and $l_2 = |Y'|$. The total number of nodes in window-based graph is $l_1 + l_2$, and the window-based graph is a bi-clique.

We also define a character-based (bipartite) graph $G_C = (V_C, E_C)$ as follows: Each window of X' has t_1 nodes in the character-based graph such that each node represents a character of the window. Similarly, each window of Y' has t_2 nodes in the character-based graph. Two nodes x, y in the character-based graph are adjacent iff $(x, y) \in \mathsf{opt}_{i,j}$ where w_i is the window containing character x and w_j is the window containing character y. Hence, the total number of nodes in character-based graph is $l_1 t_1 + l_2 t_2$. The total number of edges in character-based graph satisfy

$$l_1 l_2 \lambda \sqrt{t_1 t_2} \leq |E(G_C)| \leq l_1 l_2 \min\{t_1, t_2\}.$$

The average degree of the character-based graph is at least $2l_1l_2\lambda\sqrt{t_1t_2}/(l_1t_1+l_2t_2)$. By Blakley-Roy inequality (Lemma 30.5.3), the number of walks of length 3 in the character-based graph is at least

$$|V(G_C)|\cdot\left(2\frac{l_1l_2\lambda\sqrt{t_1t_2}}{l_1t_1+l_2t_2}\right)^3 = (l_1t_1+l_2t_2)\cdot\left(2\frac{l_1l_2\lambda\sqrt{t_1t_2}}{l_1t_1+l_2t_2}\right)^3$$
$$= 8\lambda^3\frac{(l_1l_2\sqrt{t_1t_2})^3}{(l_1t_1+l_2t_2)^2}.$$

But many of the 3-walks are degenerate. For the number of 2-walks, we can upper bound it by

$$\#\text{2-walks} \le (\text{max degree of } G_W)\cdot 2|E(G_C)| \le \max\{l_1,l_2\}\cdot 2(l_1l_2\min\{t_1,t_2\}) = 2(1+O(\epsilon))l_1^2l_2t_1.$$

Note that the #1-walks is $2|E(G_C)|$. We have

$$\begin{aligned}\frac{\#\text{2-walks}+\#\text{1-walks}}{\#\text{3-walks}} &\le \frac{2(1+O(\epsilon))l_1^2l_2t_1+2l_1l_2\min\{t_1,t_2\}}{\left(8\lambda^3\frac{(l_1l_2\sqrt{t_1t_2})^3}{(l_1t_1+l_2t_2)^2}\right)}\\ &< \frac{(l_1t_1+l_2t_2)^2l_1^2l_2t_1}{2\lambda^3l_1^3l_2^3t_1^{1.5}t_2^{1.5}}\\ &\le \frac{(1+O(\epsilon))l_1^4l_2t_1^3}{2\lambda^3l_1^{4.5}l_2^{1.5}t_1^3}\\ &= \frac{1+O(\epsilon)}{2\lambda^3l_1^{0.5}l_2^{0.5}}\\ &\le O(\epsilon),\end{aligned}$$

where the second step and third step follow from $l_1t_1 = (1\pm O(\epsilon))l_2t_2$, and the last step follows from $l_1 = \Omega(1/(\epsilon\lambda^3)), l_2 = \Omega(1/(\epsilon\lambda^3))$. Hence, the total number of 3-paths (3-walks that are not degenerate) is at least

$$8(1-O(\epsilon))\lambda^3\frac{(l_1l_2\sqrt{t_1t_2})^3}{(l_1t_1+l_2t_2)^2}.$$

On the other hand, the number of 4-tuples in window-based graph is $8\binom{l_1}{2}\binom{l_2}{2} \leq 2l_1^2 l_2^2$. Thus, there must exist a 4-tuple containing 3-walks with size at least,

$$\begin{aligned}
8(1-O(\epsilon))\lambda^3 \frac{(l_1 l_2 \sqrt{t_1 t_2})^3}{(l_1 t_1 + l_2 t_2)^2} \cdot \frac{1}{2l_1^2 l_2^2} &= 4(1-O(\epsilon))\lambda^3 \sqrt{t_1 t_2} \cdot \frac{l_1 l_2 t_1 t_2}{(l_1 t_1 + l_2 t_2)^2} \\
&= 4(1-O(\epsilon))\lambda^3 \sqrt{t_1 t_2} \cdot \frac{1}{\frac{l_1 t_1}{l_2 t_2} + 2 + \frac{l_2 t_2}{l_1 t_1}} \\
&\geq 4(1-O(\epsilon))\lambda^3 \sqrt{t_1 t_2} \cdot \frac{1}{4+O(\epsilon)} \\
&\geq (1-O(\epsilon))\lambda^3 \sqrt{t_1 t_2},
\end{aligned}$$

where the third step follows from $l_1 t_1 = (1 \pm O(\epsilon)) l_2 t_2$. Rescaling the factor of ϵ for $|X|$ and $|Y|$ completes the proof. □

Definition 30.3.4 (reconstructive tuple)**.** We say a tuple $\langle w_i, w_a, w_b, w_j \rangle$ is *reconstructive* if it is (ϵ, λ)-constructive and also $(i,a), (a,b), (b,j), (i,j) \in E(\mathsf{NG}_\lambda)$.

Before proving Lemma 30.3.5, we need to define a new graph NF_λ,

Definition 30.3.5 (NF_λ)**.** We construct a graph NF_λ in the following way: for each node $v \in \mathsf{NG}_\lambda$ we keep v in NF_λ with probability $p = k^{-\alpha}/4$ where $\alpha = 1 - \gamma/4$. For each $u, v \in \mathsf{NF}_\lambda$, if $(u,v) \in \mathsf{NG}_\lambda$ then we also draw an edge u, v in NF_λ.

It is obvious that $V(\mathsf{NF}_\lambda) \subseteq V(\mathsf{NG}_\lambda)$ and $E(\mathsf{NF}_\lambda) \subseteq E(\mathsf{NG}_\lambda)$.

Based on definition of NF_λ, we are able to show that if NG_λ is dense, so is NF_λ.

Claim 30.3.3 (NF_λ is a dense graph)**.** *Let* $\mathsf{w}_{\mathsf{layers}}$ *be the number of different window sizes. Let* NG_λ *denote a graph such that* $|E(\mathsf{NG}_\lambda)| \geq k^{2-\beta} \cdot \mathsf{w}_{\mathsf{layers}}^2$ *for some* β *and* NF_λ *be defined as Definition 30.3.5. If* $\gamma/4 - \beta = \Omega(1)$*, then with probability at least* 0.98*, we have*

$$|E(\mathsf{NF}_\lambda)| = \Omega(|V(\mathsf{NF}_\lambda)|^{2-4\beta/\gamma} \cdot \mathsf{w}_{\mathsf{layers}}^2)$$

Proof. Based on the sampling rate, we know that the following hold in expectation:

$$\mathbb{E}[|V(\mathsf{NF}_\lambda)|] = \frac{1}{4k^\alpha}|V(\mathsf{NG}_\lambda)|, \quad \text{and} \quad \mathbb{E}[|E(\mathsf{NF}_\lambda)|] = \frac{1}{4^2k^{2\alpha}}|E(\mathsf{NG}_\lambda)|.$$

Using standard Chernoff bound, we have with probability 0.99,

$$|V(\mathsf{NF}_\lambda)| \in [1/2, 2] \cdot \frac{1}{4k^\alpha}|V(\mathsf{NG}_\lambda)| = [1/2, 2] \cdot \frac{1}{4}k^{1-\alpha} = [1/2, 2] \cdot \frac{1}{4}k^{\gamma/4},$$

To show the concentration of $|E(\mathsf{NF}_\lambda)|$, we define a random variable $x_{u,v}$ such that $x_{u,v} = 1$ if $(u, v) \in E(\mathsf{NF}_\lambda)$, 0 otherwise. Then we have

$$\begin{aligned}
&\mathbb{E}\left[|E(\mathsf{NF}_\lambda)|^2\right] \\
=\ &\mathbb{E}\left[\left(\sum_{(u,v)\in E(\mathsf{NG}_\lambda)} x_{u,v}\right)^2\right] \\
=\ &\mathbb{E}\left[\sum_{(u,v)\in E(\mathsf{NG}_\lambda)} x_{u,v}^2\right] + \mathbb{E}\left[\sum_{(u,v),(u,v')\in E(\mathsf{NG}_\lambda)} \mathbf{1}_{v\neq v'} x_{u,v}x_{u,v'}\right] \\
&+ \mathbb{E}\left[\sum_{(u,v)\in E(\mathsf{NG}_\lambda)} \sum_{(u',v')\in E(\mathsf{NG}_\lambda)} \mathbf{1}_{u\neq v\neq u'\neq v'} x_{u,v}x_{u',v'}\right] \\
\leq\ &p^2|E(\mathsf{NG}_\lambda)| + p^3 \cdot \#\text{2-walks} + p^4 \cdot \left(|E(\mathsf{NG}_\lambda)|^2 - \#\text{2-walks} - |E(\mathsf{NG}_\lambda)|\right).
\end{aligned}$$

Since $\mathbb{E}[|E(\mathsf{NF}_\lambda)|] = p^2|E(\mathsf{NG}_\lambda)|$. Thus,

$$\begin{aligned}
\mathbb{V}[|E(\mathsf{NF}_\lambda)|] =\ &\mathbb{E}\left[(|E(\mathsf{NF}_\lambda)|)^2\right] - (\mathbb{E}[|E(\mathsf{NF}_\lambda)|])^2 \\
&\leq p^2|E(\mathsf{NG}_\lambda)| + p^3 \cdot \#\text{2-walks} \\
&\leq p^2|E(\mathsf{NG}_\lambda)| + p^3|V(\mathsf{NG}_\lambda)| \cdot |E(\mathsf{NG}_\lambda)| \\
&\leq 2p^3|V(\mathsf{NG}_\lambda)| \cdot |E(\mathsf{NG}_\lambda)|. \qquad \text{by } p|V(\mathsf{NG}_\lambda)| \geq 1
\end{aligned}$$

In order to use Chebyshev's inequality, we need to make sure

$$p^2|E(\mathsf{NG}_\lambda)| > 1, \quad p^2|E(\mathsf{NG}_\lambda)| \geq 100(2p^3|V(\mathsf{NG}_\lambda)||E(\mathsf{NG}_\lambda)|)^{1/2}.$$

By $p = k^{\gamma/4-1}/4$ and $|E(\mathsf{NG}_\lambda)| \geq k^{2-\beta}$, we need

$$k^{\gamma/2-\beta}/16 > 1,$$

and the second condition is equivalent to

$$p|E(\mathsf{NG}_\lambda)| \geq 20000|V(\mathsf{NG}_\lambda)|.$$

We just need $k^{\gamma/4-\beta} \geq 80000$.

Using Chebyshev's inequality, we have

$$\Pr\left[\left||E(\mathsf{NF}_\lambda)| - \mathbb{E}[|E(\mathsf{NF}_\lambda)|]\right| \geq \tau\sqrt{\mathbb{V}[|E(\mathsf{NF}_\lambda)|]}\right] \leq \frac{1}{\tau^2}$$

combining with $\sqrt{\mathbb{V}[|E(\mathsf{NF}_\lambda)|]} \leq \frac{1}{100}\,\mathbb{E}[|E(\mathsf{NF}_\lambda)|]$ together implies

$$\Pr\left[\left||E(\mathsf{NF}_\lambda)| - \mathbb{E}[|E(\mathsf{NF}_\lambda)|]\right| \geq \tau\frac{1}{100}\,\mathbb{E}[|E(\mathsf{NF}_\lambda)|]\right] \leq \frac{1}{\tau^2}.$$

Choosing $\tau = 10$, we have with probability 0.99 that $|E(\mathsf{NF}_\lambda)| > 0.9\,\mathbb{E}[|E(\mathsf{NF}_\lambda)|]$, and consequently

$$\begin{aligned}
|E(\mathsf{NF}_\lambda)| &> 0.9\,\mathbb{E}[|E(\mathsf{NF}_\lambda)|] \\
&\geq 0.9\frac{1}{4^2k^{2\alpha}}|E(\mathsf{NG}_\lambda)| \\
&\geq 0.9\frac{1}{4^2}k^{\gamma/2-2}k^{2-\beta}\cdot\mathsf{w}_{\mathsf{layers}}^2 \\
&= 0.9\frac{1}{4^2}k^{\gamma/2-\beta}\cdot\mathsf{w}_{\mathsf{layers}}^2 \\
&\geq 0.9\frac{1}{4^2}k^{\frac{\gamma}{4}(2-4\beta/\gamma)}\cdot\mathsf{w}_{\mathsf{layers}}^2 \\
&\geq \Omega(|V(\mathsf{NF}_\lambda)|^{2-4\beta/\gamma}\cdot\mathsf{w}_{\mathsf{layers}}^2).
\end{aligned}$$

Thus, we complete the proof. □

Next, we show

Claim 30.3.4 (NF_λ has no reconstructive tuple)**.** *Let* NF_λ *be defined as Definition 30.3.5. With probability at least* 0.99*, there is no reconstructive tuple in* NF_λ.

Proof. By Lemma 30.3.1 and the definition of NG_λ, there is no pair of windows (w_i, w_j) in NG_λ such that pair (i, j) is well-connected. Formally speaking, for all pairs of windows (w_i, w_j), there are at most $k^{2-\gamma}$ pairs of windows (w_a, w_b) such that $\langle w_i, w_a, w_b, w_j\rangle$ is (ϵ, λ)-constructive.

For a fixed (i, a, b, j), the probability that we keep it in NF_λ is $(k^{-\alpha}/4)^4$. We can compute the expected number of constructive tuples in NF_λ,

$$\mathbb{E}[\#\text{constructive tuple}] \le k^2 k^{2-\gamma} \cdot (k^{-\alpha}/4)^4 = k^{4-\gamma-4\alpha}/256 = 1/256$$

where the last step follows from $\alpha = 1 - \gamma/4$.

By Markov's inequality, we have

$$\Pr[\#\text{constructive tuple} \ge 1/2] \le \frac{\mathbb{E}[\#\text{constructive tuple}]}{1/2} \le 1/100.$$

Thus, with probability 0.99, there is no reconstructive tuple in NF_λ. □

Finally, we use Lemma 30.3.2 to prove an upper bound on the number of edges in NG_λ.

Lemma 30.3.5. *Let* NG_λ *be as defined in Definition 30.3.3. Then with probability at least* 0.9*,* NG_λ *has at most* $k^{2-\Omega(\gamma\lambda\epsilon/\mathsf{w}_{\mathsf{gap}})} \cdot \mathsf{w}_{\mathsf{layers}}^2$ *edges.*

Proof. We start with assuming

$$|E(\mathsf{NG}_\lambda)| \geq k^{2-\beta} \cdot \mathsf{w}_{\mathsf{layers}}^2,$$

and will get the contradiction at the end.

We construct a graph NF_λ based on Definition 30.3.5. Using Claim 30.3.4, we know that NF_λ has no reconstructive tuple. Next, we are going to show two facts, and they are contradicting to each other by some choice of β.

(Fact A). Note that NF_λ does not satisfy the assumption in Lemma 30.3.2, thus we cannot apply Lemma 30.3.2 to NF_λ directly. Let $\mathsf{w}_{\mathsf{layers}}$ denote the number of different window sizes in total, we can decompose NF_λ into $\mathsf{w}_{\mathsf{layers}}^2$ graphs such that $\mathsf{NF}_\lambda^{i,j}$ only involves size i and j, $\forall i, j \in [\mathsf{w}_{\mathsf{layers}}] \times [\mathsf{w}_{\mathsf{layers}}]$. Now, applying Lemma 30.3.2, for every i, j, we imply that if $\mathsf{NF}_\lambda^{i,j}$ has no reconstructive tuple, then $\mathsf{NF}_\lambda^{i,j}$ has no bipartite graph of certain size, i.e., $K_{\Omega(\mathsf{w}_{\mathsf{gap}}/(\epsilon\lambda^3)),\Omega(\mathsf{w}_{\mathsf{gap}}/(\epsilon\lambda^3))}$.

(Fact B). Using the Turán's Theorem (Lemma 30.5.4), we know for any integer $s \geq 2$, a graph G with n vertices and $\Omega(n^{2-1/s})$ edges has at least one $K_{s,s}$ subgraph. We consider graph NF_λ. Since

$$|E(\mathsf{NF}_\lambda)| = \Omega(|V(\mathsf{NF}_\lambda)|^{2-4\beta/\gamma} \cdot \mathsf{w}_{\mathsf{layers}}^2),$$

by Claim 30.3.3, $|E(\mathsf{NF}_\lambda)| = \Omega(|V(\mathsf{NF}_\lambda)|^{2-4\beta/\gamma} \cdot \mathsf{w}_{\mathsf{layers}}^2)$. By the pigeonhole principle, there exist i and j such that $|E(\mathsf{NF}_\lambda^{i,j})| = \Omega(|V(\mathsf{NF}_\lambda)|^{2-4\beta/\gamma})$. By Turán's Theorem, such an $\mathsf{NF}_\lambda^{i,j}$ contains a large complete bipartite subgraph $K_{\gamma/(4\beta),\gamma/(4\beta)}$.

In order to get a contraction, we just need

$$\gamma/(4\beta) \geq c \cdot \mathsf{w}_{\mathsf{gap}}/(\epsilon\lambda^3).$$

for some sufficiently large constant $c > 1$ related to Lemma 30.3.2. Thus, we have

$$\beta \le \gamma\epsilon\lambda^3/(4c \cdot \mathsf{w}_{\mathsf{gap}}).$$

□

Theorem 30.3.6 (quadratic sparsification for constant λ)**.** *Given k windows $w_1, \cdots, w_k$. Let $\mathsf{w}_{\mathsf{max}} = \max_{i\in[k]} |w_i|$, $\mathsf{w}_{\mathsf{min}} = \min_{i\in[k]} |w_i|$ and $\mathsf{w}_{\mathsf{gap}} = \mathsf{w}_{\mathsf{max}}/\mathsf{w}_{\mathsf{min}}$. Let the number of different window sizes be $\mathsf{w}_{\mathsf{layers}}$. For any $\lambda \in (0,1)$ and $\epsilon \in (0, 1/10)$, there is a randomized algorithm (Algorithm 30.1) that runs in time*

$$O(\mathsf{w}_{\mathsf{max}}^2 k^{1.1} \log k + \mathsf{w}_{\mathsf{max}} k^{2.2} \log^2 k),$$

outputs a table $\widehat{\mathsf{O}}_{\lambda^2} \in \{0,1\}^{k\times k}$ such that

$$\|\mathsf{lcs}(w_i, w_j)\| \ge (1-\epsilon)\lambda^3, \text{ if } \widehat{\mathsf{O}}_{\lambda^2}[i][j] = 1$$

and

$$\left|\left\{(i,j) \;\middle|\; \|\mathsf{lcs}(w_i,w_j)\| \ge \lambda, \quad \text{and} \quad \widehat{\mathsf{O}}_{\lambda^2}[i][j] = 0\right\}\right| = O\left(k^{2-\Omega(\lambda\epsilon/\mathsf{w}_{\mathsf{gap}})} \cdot \mathsf{w}_{\mathsf{layers}}^2\right).$$

The algorithm has success probability $1/\operatorname{poly}(k)$.

Proof. The overall running time is

$$\begin{aligned}
&O(k|S|\mathsf{w}_{\mathsf{max}}^2 + k^2|S|^2\mathsf{w}_{\mathsf{max}}) \\
&= O(k \cdot k^\gamma \log k \cdot \mathsf{w}_{\mathsf{max}}^2 + k^2 \cdot k^{2\gamma} \log^2 k \cdot \mathsf{w}_{\mathsf{max}}) \\
&= O(k^{1.1} \log k \cdot \mathsf{w}_{\mathsf{max}}^2 + k^{2.2} \log^2 k \cdot \mathsf{w}_{\mathsf{max}})
\end{aligned}$$

where the first step follows from $|S| = O(k^\gamma \log k)$, the second step follows from $\gamma = 0.1$.

The guarantee of table $\widehat{\mathsf{O}}_{\lambda^2}$ follows from properties of graph NG_λ (Algorithm 30.1 provides the first property of table in Theorem statement, Lemma 30.3.5 provides the second property of table in Theorem statement). □

30.3.2 Sparsification for O_{λ^3}

One shortcoming of Lemma 30.3.5 is that the number of remaining edges is only truly subquadratic if λ is constant. As we discuss in Section 30.3.1, the overall running time of the algorithm depends on the number of edges in the remaining graph and in order for the running time to be truly subquadratic, we need to reduce the number of edges to truly subquadratic. In this section, we show how one can obtain this bound even when λ is super-constant. However, instead of losing a factor λ^2 in the approximation, our technique loses a factor of $O(\lambda^3)$.

Definition 30.3.6 ($\mathsf{lcs}_{w_a}(w_i, w_j)$)**.** For two windows w_i and w_j, and a window w_a, define $\mathsf{lcs}_{w_a}(w_i, w_j)$ as the length of LCS of $\mathsf{opt}_{i,a}$ and w_j, where $\mathsf{opt}_{i,a}$ denotes the LCS of w_i and w_a.

Notice that unlike lcs, this new definition is not symmetric. Similar to lcs, we also normalize the size of lcs_s by the geometric mean of the lengths of the two windows. That is, we divide the size of the common string by $\sqrt{|w_i||w_j|}$. In what follows, we first give an algorithm for detecting close pairs of windows, and then prove that the number of remaining pairs whose lcs is at least λ is truly subquadratic.

Our algorithm is based on a data structure which we call $\mathsf{lcs\text{-}cmp}(w_a, S, \widetilde{\lambda})$. Roughly

speaking, we will choose $\widetilde{\lambda} = \lambda^2$ when we use it. Let us fix a threshold $\widetilde{\lambda}$ and a window w_a. $\mathsf{lcs\text{-}cmp}(w_a, S, \widetilde{\lambda})$ receives a set S of windows as input such that the size of each window of S is at least $|w_a|$. Upon receiving the windows, it makes a preprocess in time $O(\widetilde{\lambda}^{-2}|w_a|\sum_{w_i \in S}|w_i|)$. Next, $\mathsf{lcs\text{-}cmp}(w_a, S, \widetilde{\lambda})$ would be able to answer each query of the following form in almost linear time:

- For two windows $w_i, w_j \in S$, either certify that $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| < \widetilde{\lambda}/2$ or find a solution for $\|\mathsf{lcs}_{w_a}(w_i, w_j)\|$ with a size of at least $\widetilde{\lambda}^2/8$.

We first show in Section 30.3.2.1, how lcs-cmp gives us a sparsification in truly sublinear time and then discuss the algorithm for lcs-cmp in Section 30.3.2.2.

30.3.2.1 λ^3 Sparsification using lcs-cmp

Similar to what we did in Section 30.3.1, we again use a parameter γ in our algorithm and in the end, we adjust γ to minimize the total running time. In our algorithm, we repeat the following procedure $k^\gamma \log k$ times: sample a window w_a uniformly at random and let S be the set of all the other windows whose length is not smaller than $|w_a|$. Next, we obtain $\mathsf{lcs\text{-}cmp}(w_a, S, \widetilde{\lambda})$ via running the preprocessing step. Finally, for each pair of windows $w_i, w_j \in S$, we make a query to lcs-cmp to verify one of the following two possibilities:

- $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| < \lambda^2/2$;
- $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| \geq \lambda^4/8$.

If the latter is verified we set $\widehat{\mathsf{O}}_{\lambda^3/8}[i][j]$ to 1 otherwise we take no action. In what follows, we prove that after the above sparsification, the number of edges in the remaining graph is

truly sublinear.

Algorithm 30.2 Sparsification for O_{λ^3}

          $\widehat{\mathsf{O}}_{\lambda^3/8}[i][j] \leftarrow 1$ ▷ $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| \geq \widetilde{\lambda}^2/8$
        end if
      end for
    end for
  end for
  return $\widehat{\mathsf{O}}_{\lambda^3/8}$
end procedure

In the rest of this section, we bound $|\{(i,j) \mid \|\mathsf{lcs}(w_i, w_j)\| \geq \lambda \text{ and } \widehat{\mathsf{O}}_{\lambda^3/8}[i][j] = 0\}|$. In other words, we prove an upper bound on the number of edges that remain in the graph. Define a graph NG_λ such that each vertex of NG_λ corresponds to a window and an edge (i,j) means that $\|\mathsf{lcs}(w_i, w_j)\| \geq \lambda$ but $\widehat{\mathsf{O}}_{\lambda^3/8}[i][j] = 0$. The goal is to prove an upper bound on the number of edges of NG_λ. We formally prove this in Lemma 30.3.9.

We define a notation called "close" which is similar to "well-connected" in Section 30.3.1.

In order to avoid confusion, we use "close" instead of well-connected.

Definition 30.3.7 (close)**.** Let $\gamma \in (0,1)$ and $\lambda \in (0,1)$. We say a pair (w_i, w_j) of windows is *close*, if there are at least $k^{1-\gamma}$ windows w_a such that $|w_a| \leq \min\{|w_i|, |w_j|\}$ and $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| \geq \lambda^2$.

Our first observation is that Algorithm 30.2 detects all the close pairs with high probability.

Lemma 30.3.7. *Let $\widehat{\mathsf{O}}_{\lambda^3/8} \in \{0,1\}^{k \times k}$ be the output of Algorithm 30.2. For each $(i,j) \in [k] \times [k]$, if (w_i, w_j) is close (Definition 30.3.7) and $\|\mathsf{lcs}(w_i, w_j)\| \geq \lambda$, then $\widehat{\mathsf{O}}_{\lambda^3/8}[i][j] = 1$ holds with probability at least $1 - 1/\operatorname{poly}(k)$.*

Proof. We consider a fixed (i,j) such that (w_i, w_j) is close. By Definition 30.3.7, there are at least $k^{1-\gamma}$ w_a such that $|w_a| \leq \min\{|w_i|, |w_j|\}$ and $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| \geq \lambda^2$. Then the probability that none of these windows is sampled is at most

$$\left(1 - \frac{k^{1-\gamma}}{k}\right)^t = \left(1 - \frac{1}{k^\gamma}\right)^t = \left(1 - \frac{1}{k^\gamma}\right)^{10k^\gamma \log k} \leq 1/\operatorname{poly}(k).$$

Taking a union over at most k^2 pairs completes the proof. □

Before we proceed to Lemma 30.3.9, we bring Lemma 30.3.8 as an auxiliary observation.

Lemma 30.3.8 (existence of a correlated pair)**.** *Let $\epsilon \in (0,1)$, $\lambda \in (0,1)$. Given a window w_a and a set of windows T. Let $\mathsf{w}_{\mathsf{gap}}$ denote the maximum size of windows divided by the minimum size of windows. Let T contain at most $\mathsf{w}_{\mathsf{layers}}$ different sizes and $|T| = \Omega(\mathsf{w}_{\mathsf{layers}} \cdot \mathsf{w}_{\mathsf{gap}}/(\epsilon\lambda))$. If for each $w_i \in T$ we have $\|\mathsf{lcs}(w_a, w_i)\| \geq \lambda$, then there exist two windows $w_i, w_j \in T$ such that $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| \geq (1-\epsilon)\lambda^2$.*

Proof. Since T has size $\Omega(\mathsf{w}_{\mathsf{layers}} \cdot \mathsf{w}_{\mathsf{gap}}/(\epsilon\lambda))$ and the windows of T have at most $\mathsf{w}_{\mathsf{layers}}$ different sizes, there must exists a subset $T' \subseteq T$ such that $|T'| = \Omega(\mathsf{w}_{\mathsf{gap}}/(\epsilon\lambda))$ and all the windows in T' have the same size. In the rest of the proof, we will focus on w_a and T'.

Let t_0 be the size of w_a and t be the size of all the windows in T'. We consider a window-based bipartite graph, on one side it has one node w_a, and on the other side it has $|T'|$ nodes. Then we can expand the window-based bipartite graph into a character-based bipartite graph, on one side it has t_0 nodes, and on the other side it has $t|T'|$ nodes. Two nodes x, y in the character-based graph are adjacent iff $(x, y) \in \mathsf{opt}_{a,i}$ where w_a is the window containing character x and w_i is the window containing character y. Since $\|\mathsf{lcs}(w_a, w_i)\| \geq \lambda$ for every $w_i \in T'$, the number of edges in character-based bipartite graph is at least $\lambda|T'|\sqrt{t_0 t}$.

For i-th character in window w_a, we use D_i to denote the degree of the corresponding node in the character-based bipartite graph. The number of 2-walks is at least

$$\begin{aligned}
\sum_{i=1}^{t_0} D_i(D_i - 1) &= \left(\sum_{i=1}^{t_0} D_i^2 - \sum_{i=1}^{t_0} D_i\right) \\
&\geq \left(\frac{1}{t_0}(\sum_{i=1}^{t_0} D_i)^2 - \sum_{i=1}^{t_0} D_i\right) && \text{by Cauchy-Schwarz inequality} \\
&\geq \left(\frac{1}{t_0}(\lambda|T'|\sqrt{t_0 t})^2 - (\lambda|T'|\sqrt{t_0 t})\right) && \text{by Eq. (30.1)} \\
&= \left(\lambda^2 t|T'|^2 - \lambda|T'|\sqrt{t_0 t}\right) \\
&\geq (1-\epsilon)\lambda^2 t|T'|^2 && \text{by } |T'| = \Omega(\mathsf{w}_{\mathsf{gap}}/(\epsilon\lambda))
\end{aligned}$$

It remains to show Eq. (30.1). Since the number of edges in the character-based bipartite graph is at least $\lambda|T'|\sqrt{t_0 t}$, we have

$$\sum_{i=1}^{t_0} D_i \geq \lambda|T'|\sqrt{t_0 t}.$$

By $|T'| = \Omega(\mathsf{w}_{\mathsf{gap}}/(\epsilon\lambda))$, we have

$$\lambda|T'|\sqrt{t_0 t} \geq t_0.$$

Due to a simple fact : $x(x-z) > y(y-z)$ as long as $x > y > z > 0$, we have

$$\frac{1}{t_0}(\sum_{i=1}^{t_0} D_i)^2 - \sum_{i=1}^{t_0} D_i \geq \frac{1}{t_0}(\lambda|T'|\sqrt{t_0 t})^2 - (\lambda|T'|\sqrt{t_0 t}). \tag{30.1}$$

The number of 3-tuple (w_i, w_a, w_j) is at most $|T'|^2$. Thus, there must exists a pair such that

$$\|\mathsf{lcs}_{w_a}(w_i, w_j)\| \geq (1-\epsilon)\lambda^2$$

□

We define graph NG_λ and NF_λ as follows:

Definition 30.3.8 (NG_λ)**.** We assume that the edges of NG_λ are directed in the following way: For an edge (i, j) if $|w_i| \neq |w_j|$ the starting point of the edge would be the vertex corresponding to the longer window and the ending point of the edge would be the one corresponding to the shorter window. If both corresponding windows have the same lengths, then we use an arbitrary direction for (i, j).

Definition 30.3.9 (NF_λ)**.** We construct graph NF_λ in the following way : let a denote the node in $V(\mathsf{NG}_\lambda)$ that has the highest outgoing degree, let $V(\mathsf{NF}_\lambda) = N(a)$. We add an edge between vertices (i, j) in NF_λ if $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| \geq (1-\epsilon)\lambda^2$. Give directions to the edges of NF_λ the same way we did it for NG_λ.

Now, we are ready to prove the main observation of this section.

Lemma 30.3.9 (upper bound on $E(\mathsf{NG}_\lambda)$)**.** *Let* NG_λ *be defined as Definition 30.3.3. Then*

$$|E(\mathsf{NG}_\lambda)| = O(k^{2-\gamma} \cdot \mathsf{w}_{\mathsf{layers}} \cdot \mathsf{w}_{\mathsf{gap}}/(\epsilon\lambda)).$$

holds with probability $1 - 1/\operatorname{poly}(k)$.

Proof. We start with assuming

$$|E(\mathsf{NG}_\lambda)| \geq \Omega(k^{2-\beta} \cdot \mathsf{w}_{\mathsf{layers}} \cdot \mathsf{w}_{\mathsf{gap}}/(\epsilon\lambda)).$$

We construct a graph NF_λ based on Definition 30.3.9. By Definition 30.3.9, we know that $|V(\mathsf{NF}_\lambda)| \geq \Omega(k^{1-\beta} \cdot \mathsf{w}_{\mathsf{layers}} \cdot \mathsf{w}_{\mathsf{gap}}/(\epsilon\lambda))$. By choosing some $\beta = \gamma$ we will make a contradiction.

Using Lemma 30.3.8, we have for each set $T \subseteq V(\mathsf{NF}_\lambda)$ with $|T| = \Omega(\mathsf{w}_{\mathsf{layers}} \cdot \mathsf{w}_{\mathsf{gap}}/(\epsilon\lambda))$, there exist two nodes u and v in T such that edge $(u, v) \in \mathsf{NF}_\lambda$.

If we look at the complement of graph NF_λ, we know there is no clique K_{r+1} where $r = O(\mathsf{w}_{\mathsf{layers}} \cdot \mathsf{w}_{\mathsf{gap}}/(\epsilon\lambda))$. Using Turan's theorem (Lemma 30.5.5) we know that complement of graph NF_λ has at most $(1 - \frac{1}{r})\frac{q^2}{2}$ edges, where $q = |V(\mathsf{NF}_\lambda)|$. Then we have

$$|E(\mathsf{NF}_\lambda)| \geq \frac{q(q-1)}{2} - (1 - \frac{1}{r})\frac{q^2}{2} = \frac{q^2}{2r} - \frac{q}{2}.$$

This implies that there is one vertex j whose outgoing degree in NF_λ is at least at least

$$\frac{|V(\mathsf{NF}_\lambda)|}{2r} - \frac{1}{2} \geq |V(\mathsf{NF}_\lambda)| \cdot \Omega\left(\frac{\epsilon\lambda}{\mathsf{w}_{\mathsf{layers}} \cdot \mathsf{w}_{\mathsf{gap}}}\right) \geq k^{1-\beta} \geq k^{1-\gamma}.$$

Thus, there is a node in NG_λ that has a lot of outgoing edges, which means NG_λ has a close pair.

On the other hand, Using definition of NG_λ and Lemma 30.3.7, we know that NG_λ should not contain any close pair. Thus, we get a contradiction. □

Theorem 30.3.10 (cubic sparsification for arbitrary λ)**.** *Given k windows $w_1, \cdots, w_k$. Let $\mathsf{w}_{\mathsf{layers}}$ denote the number of different sizes for windows. Let $\mathsf{w}_{\mathsf{max}} = \max_{i\in[k]} |w_i|$, $\mathsf{w}_{\mathsf{min}} = \min_{i\in[k]} |w_i|$ and $\mathsf{w}_{\mathsf{gap}} = \mathsf{w}_{\mathsf{max}}/\mathsf{w}_{\mathsf{min}}$. For any $\lambda \in (0,1), \gamma \in (0,1)$, there is a randomized algorithm (Algorithm 30.2) that runs in time*

$$O(\lambda^{-4} k^{1+\gamma} \mathsf{w}_{\mathsf{max}}^2 \log k + k^{2+\gamma} \mathsf{w}_{\mathsf{max}} \log k)$$

and outputs a table $\widehat{\mathsf{O}}_{\lambda^3} \in \{0,1\}^{k\times k}$ such that

$$\|\mathsf{lcs}(w_i, w_j)\| \geq \lambda^4/8, \text{ if } \widehat{\mathsf{O}}_{\lambda^3}[i][j] = 1$$

and

$$\left|\left\{(i,j) \mid \|\mathsf{lcs}(w_i,w_j)\| \geq \lambda, \quad \text{and} \quad \widehat{\mathsf{O}}_{\lambda^3}[i][j] = 0\right\}\right| = O(k^{2-\gamma} \mathsf{w}_{\mathsf{layers}} \mathsf{w}_{\mathsf{gap}}/\lambda).$$

The algorithm has success probability $1 - 1/\operatorname{poly}(k)$.

Proof. The running time of each round of Algorithm 30.2 is

$$\begin{aligned}
&= O(\text{ constructing } S \text{ time} + \mathsf{lcs\text{-}cmp}.\textsc{Initial} \text{ time} + |S|^2 \cdot (\mathsf{lcs\text{-}cmp}.\textsc{Query} \text{ time})) \\
&= O(k + \widetilde{\lambda}^{-2}|S|\mathsf{w}_{\mathsf{max}}^2 + |S|^2 \mathsf{w}_{\mathsf{max}}) \\
&= O(\lambda^{-4} k \mathsf{w}_{\mathsf{max}}^2 + k^2 \mathsf{w}_{\mathsf{max}})
\end{aligned}$$

where the last step follows by $\widetilde{\lambda} = \lambda^2$.

Since it repeats $O(k^\gamma \log k)$ rounds, thus the overall running time is

$$O(k^\gamma \log k) \cdot O(\lambda^{-4} k \mathsf{w}_{\mathsf{max}}^2 + k^2 \mathsf{w}_{\mathsf{max}}) = O(\lambda^{-4} k^{1+\gamma} \mathsf{w}_{\mathsf{max}}^2 \log k + k^{2+\gamma} \mathsf{w}_{\mathsf{max}} \log k).$$

□

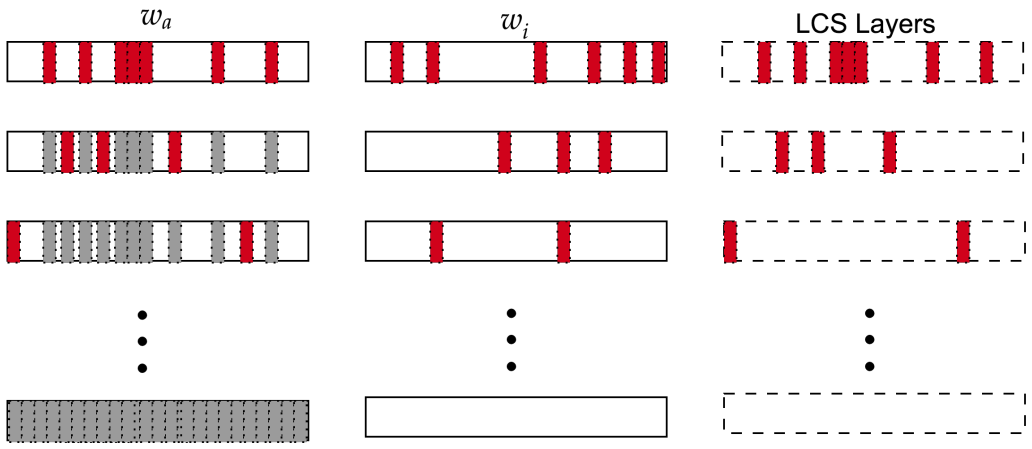

Figure 30.5: computing a set of common subsequences between w_a and w_i for each i such that every character of w_a appears at most once among the sequences for a fixed i.

30.3.2.2 Implementation of lcs-cmp

Given $\widetilde{\lambda}$, w_a and $w_1, w_2, \ldots, w_s$, we present an $O(\widetilde{\lambda}^{-1}|w_a|\sum_{i=1}^{s}|w_i|)$ time preprocessing algorithm and $O(|w_a|)$ time query algorithm for lcs-cmp such that for any $i, j \in [s]$

1. if $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| > \widetilde{\lambda}/2$, then the query algorithm outputs accept;
2. if $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| \leq \widetilde{\lambda}^2/8$, then the query algorithm outputs reject.

Algorithm 30.3 is our lcs-cmp preprocessing and query algorithm. The high level idea is to compute $\mathsf{opt}_{a,i}$ for every $i \in [s]$ and a set of at most $2/\lambda$ common subsequences between w_a and w_i for each i such that every character of w_a appears at most once among the sequences for a fixed i. $\mathsf{lcs}_{w_a}(w_i, w_j)$ is approximated by taking the longest intersection of $\mathsf{opt}_{a,i}$ and some sequence in the set of window w_j. Also see Figure 30.5 for the intuition.

Now we prove that Algorithm 30.3 implements lcs-cmp.

Lemma 30.3.11 (INITIAL)**.** *Given parameter $\widetilde{\lambda}$, a window w_a and a set of windows $w_1, \cdots, w_s$. The* INITIAL *of data structure* lcs-cmp *(Algorithm 30.3) takes $O(\widetilde{\lambda}^{-1}|w_a| \sum_{i=1}^{s} |w_i|)$ time, and outputs $\{X_{a,i}\}_{i\in[s]}$ and $\{Y_{a,i}\}_{i\in[s]}$ such that*

1. *$X_{a,i}$ corresponds to indices of a longest common subsequence between w_a and w_i for every $i \in [s]$.*
2. *$Y_{a,i}$ corresponds to indices of at most $2/\widetilde{\lambda}$ common subsequence between w_a and w_i for every $i \in [s]$.*
3. *If none of the element indices of a common subsequence between w_a and w_i is in $Y_{a,i}$, then the length of this common subsequence is less than $\widetilde{\lambda}|w_a|$.*

Proof. The first property follows from the definition of the algorithm.

For the second and third property, if an $\mathsf{opt}'_{a,i}$ obtained in Line 9 has length less than $\widetilde{\lambda}|w_a|/2$, then the element indices of $\mathsf{opt}'_{a,i}$ are not in $Y_{a,i}$. Hence, the third property holds. Also, it means that every time that Line 13 is executed, the size of $Y_{a,i}$ increases by at least $\widetilde{\lambda}|w_a|/2$. For a fixed $i \in [s]$, Line 13 is executed at most $2/\widetilde{\lambda}$ times. Thus, the second property holds.

The running time is also obtained by the fact that Line 13 is executed at most $2/\widetilde{\lambda}$ times for every fixed $i \in [s]$. □

Lemma 30.3.12 (QUERY)**.** *For any $(i, j) \in [s] \times [s]$, the* QUERY *of data structure* lcs-cmp *(Algorithm 30.3) runs in time $O(|w_a|)$ with the following properties:*

1. *If* $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| > \widetilde{\lambda}/2$*, then it outputs accept.*

2. *If* $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| \leq \widetilde{\lambda}^2/8$*, then it outputs reject.*

Proof. Let $\mathsf{opt}_{a,i,j}$ be the LCS between $\mathsf{opt}_{a,i}$ and w_j. By the definition, we have

$$\|\mathsf{lcs}_{w_a}(w_i, w_j)\| = \frac{|\mathsf{opt}_{a,i,j}|}{\sqrt{|w_i| \cdot |w_j|}}$$

Consider the case of $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| \geq \widetilde{\lambda}/2$. By the third property of Lemma 30.3.11, there are less than $\widetilde{\lambda}|w_a|/4$ elements of $\mathsf{opt}_{a,i,j}$ with indices not in $Y_{a,j}$. So we have

$$|X_{a,i} \cap Y_{a,j}| > \frac{1}{2}\widetilde{\lambda}\sqrt{|w_i||w_j|} - \frac{1}{4}\widetilde{\lambda}|w_a| \geq \frac{1}{4}\widetilde{\lambda}\sqrt{|w_i||w_j|}$$

where the last inequality follows from the fact that $|w_a|$ is smaller than or equal to $|w_i|$ for every $i \in [s]$. Hence the algorithm accepts.

Consider the case of $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| \leq \widetilde{\lambda}^2/8$. By the second property of Lemma 30.3.11, $Y_{a,j}$ corresponds to at most $2/\widetilde{\lambda}$ mutually non-overlapping common subsequence between w_a and w_j. Since $\|\mathsf{lcs}_{w_a}(w_i, w_j)\| \leq \widetilde{\lambda}^2/8$, the set of indices of every such a common subsequence has an intersection with $X_{a,i}$ of size at most $\widetilde{\lambda}^2\sqrt{|w_i||w_j|}/8$. Thus, we have

$$|X_{a,i} \cap Y_{a,j}| \leq \frac{1}{8}\widetilde{\lambda}^2\sqrt{|w_i||w_j|} \cdot \frac{2}{\widetilde{\lambda}} \leq \frac{1}{4}\widetilde{\lambda}\sqrt{|w_i||w_j|}.$$

Hence the algorithm rejects for this case. □

30.4 Longest Increasing Subsequence

We outlined the algorithm in Section 30.1.3.3. Here, we bring the details for each step of the algorithm. In Section 30.4.1 we discuss the solution domains and show how we construct them. Next, in Section 30.4.2 we discuss the details of constructing pseudo-solutions and finally in Section 30.4.3 we show how we can obtain an approximate solution from the pseudo-solutions. Also, in Section 30.4.4 we bring an improvement to the running time at the expense of having a larger approximation factor for the algorithm.

30.4.1 Solution Domains

We assume from now on that $\mathsf{lis}(A) > n\lambda$ holds. As mentioned earlier, we divide the input array into $\sqrt{n}$ subarrays of size $\sqrt{n}$ and denote them by $\mathsf{sa}_1, \mathsf{sa}_2, \ldots, \mathsf{sa}_{\sqrt{n}}$. For a fixed optimal solution opt, our goal is to approximate the smallest and the largest number of each subarray that contributes to opt. Let us refer to these numbers as the *domain* of each subarray. Let $\epsilon = 1/1000$ be accuracy. For a subarray sa_i, we sample k (will be decided later) different elements and refer to them by $a_{j_1}, a_{j_2}, \ldots, a_{j_k}$.

We first prove that,

Lemma 30.4.1 (constructing candidate domains)**.** *Let $\lambda \in (0,1)$, $\epsilon \in (0,1/2)$ and $\delta \in (0,1/10)$. Let sa_i be a length-$\sqrt{n}$ subarray whose contribution to the optimal solution is at least $\epsilon\sqrt{n}\lambda$, i.e., $\mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i) \geq \epsilon\sqrt{n}\lambda$. If we uniformly sample $k = 20\log(1/\delta)/(\lambda\epsilon^2)$ elements $a_{j_1}, a_{j_2}, \ldots, a_{j_k}$ from sa_i, then with probability at least $1-\delta$, there exists a pair $(\alpha, \beta) \in [k] \times [k]$ such that the following two conditions hold*

1. $\mathsf{sm}(\mathsf{sa}_i) \leq a_{j_\alpha} \leq a_{j_\beta} \leq \mathsf{lg}(\mathsf{sa}_i)$,

2. $\mathsf{lis}^{[a_{j_\alpha}, a_{j_\beta}]}(\mathsf{sa}_i) \geq (1-\epsilon)\mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i), \mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i)$.

Proof. At least $\epsilon\sqrt{n}\lambda$ elements of sa_i appear in opt. Let us put all these elements in an array b in the same order that they appear in sa_i. Then it is obvious that b has at least $\epsilon\sqrt{n}\lambda$ elements. To prove the lemma, we bound the probability that none of the first $\epsilon/2$ fraction of the elements of b is sampled in our algorithm.

$$
\begin{aligned}
& \Pr[\text{none of the elements in the first } \epsilon/2 \text{ fraction of } \mathsf{b} \text{ is sampled}] \\
\leq\ & \left(1 - \frac{\epsilon}{2} \cdot \epsilon\sqrt{n}\lambda \cdot \frac{1}{\sqrt{n}}\right)^k \\
=\ & \left(1 - \frac{\epsilon^2\lambda}{2}\right)^{\frac{2}{\epsilon^2\lambda} \cdot 10\log(1/\delta)} \\
\leq\ & e^{-10\log(1/\delta)} \\
\leq\ & \delta/2,
\end{aligned}
$$

where the first step follows from the fact that b contains at least $\epsilon\lambda\sqrt{n}$ elements, the second step follows from $k = 20\log(1/\delta)/(\lambda\epsilon^2)$, and the third step follows from the fact that the $(1-1/x)^x \leq 1/e$ for $\forall x \geq 4$. Hence, with probability at least $1-\delta/2$, at least one of the elements in the first $\epsilon/2$ fraction of b are sampled.

With the same analysis, one can prove that with probability at least $1-\delta/2$ at least one of the elements in the last $\epsilon/2$ fraction of b are also sampled.

Taking a union bound of two events, with probability at least $1-\delta$, at least one of the elements in the first and at least one of the elements in the last $\epsilon/2$ fraction of b are sampled.

Therefore, the lis of sa_i subject to this interval is at least a $1-\epsilon$ fraction of $\mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i)$.

□

Notice that the average contribution of each subarray to opt is $\sqrt{n}\lambda$ and Lemma 30.4.1 applies to a subarray if its contribution to opt is at least an ϵ fraction of this value. Therefore Lemma 30.4.1 implies that a considerable fraction of the solution is covered by the candidate domains.

Corollary 30.4.2 (existence of a desirable solution)**.** *Let $\lambda \in (0,1)$ such that $\mathsf{lis}(A) \geq n\lambda$ and $\epsilon \in (0, 1/4)$. If we run Algorithm 30.4 with parameter $\delta = \epsilon$ on every subarray independently, then with probability at least $1 - \exp(-\Omega(\epsilon^2\sqrt{n}\lambda))$, there exist a set $T \subseteq [\sqrt{n}]$ and elements α_i and β_i sampled from sa_i for each $i \in T$ such that the following conditions hold:*

1. *For any $i \in T$, $\alpha_i \leq \beta_i$.*
2. *For any $i, j \in T$ satisfying $i < j$, $\beta_i < \alpha_j$.*
3. *$\sum_{i\in T} \mathsf{lis}^{[\alpha_i,\beta_i]}(\mathsf{sa}_i) \geq (1-4\epsilon)\mathsf{lis}(A)$.*

Proof. Lemma 30.4.1 holds for all subarrays whose contribution to opt is at least $\epsilon\sqrt{n}\lambda$. Let $S \subseteq [\sqrt{n}]$ denote the set of coordinates such that for each $i \in S$

$$\mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i) \geq \epsilon\sqrt{n}\lambda.$$

Since $\sum_{i=1}^{\sqrt{n}} \mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i) \geq n\lambda$ and $\mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i) \leq \sqrt{n}$, we have

$$\sum_{i\in S} \mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i) \geq \sum_{i=1}^{\sqrt{n}} \mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i) - \sqrt{n}\cdot\epsilon\sqrt{n}\lambda \geq \mathsf{lis}(A) - \epsilon n\lambda. \tag{30.2}$$

Let $T \subseteq S$ denote the set of coordinates such that for each $i \in T$,

$$\mathsf{lis}^{[\alpha_i,\beta_i]}(\mathsf{sa}_i) \geq (1-\epsilon)\mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i), \quad \text{and} \quad \mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i) \geq \epsilon\sqrt{n}\lambda.$$

Now we show that with probability at least $1 - \exp(-\Omega(\epsilon^2\sqrt{n}\lambda))$,

$$\sum_{i\in T} \mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i) \geq (1-2\epsilon)\sum_{i\in S} \mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i). \tag{30.3}$$

For each $i \in S$, let X_i denote a random variable such that

$$X_i = \begin{cases} \mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i), & \text{with probability of } i \in T; \\ 0, & \text{with probability of } i \notin T, \end{cases}$$

and $X = \sum_{i\in S} X_i$. By Lemma 30.4.1 (with $\delta = \epsilon$), We have $\mathbb{E}[X] \geq (1-\epsilon)\sum_{i\in S} \mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i)$. By Hoeffding bound (Theorem 30.5.2),

$$\begin{aligned}
\Pr[X - \mathbb{E}[X] \geq \epsilon\,\mathbb{E}[X]] &\leq 2\exp\left(-\frac{2\epsilon^2(\mathbb{E}[X])^2}{\sum_{i\in S}\left(\mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i)\right)^2}\right) \\
&\leq 2\exp\left(-\frac{2\epsilon^2(1-\epsilon)^2\left(\sum_{i\in S}\mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i)\right)^2}{n^{3/2}}\right) \\
&\leq 2\exp(-2\epsilon^2(1-\epsilon)^4\sqrt{n}\lambda) \\
&\leq \exp(-\Omega(\epsilon^2\sqrt{n}\lambda)).
\end{aligned}$$

Hence, Equation (30.3) holds with probability at least $1 - \exp(-\Omega(\epsilon^2\sqrt{n}\lambda))$.

Conditioned on Equation (30.3), we have

$$\begin{aligned}
&\sum_{i\in T} \mathsf{lis}^{[\alpha_i, a_{\beta_i}]}(\mathsf{sa}_i) \\
&\geq \sum_{i\in T} (1-\epsilon)\mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i) \\
&\geq (1-\epsilon)(1-2\epsilon)\sum_{i\in S} \mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i),\mathsf{lg}(\mathsf{sa}_i)]}(\mathsf{sa}_i) \\
&\geq (1-\epsilon)(1-2\epsilon)(\mathsf{lis}(A) - \epsilon n\lambda) \\
&\geq (1-4\epsilon)\mathsf{lis}(A)
\end{aligned} \tag{30.4}$$

where the first inequality follows from the definition of T, the second inequality follows from Equation (30.3), the third inequality follows from Equation (30.2) and the last inequality follows from $\mathsf{lis}(A) \geq n\lambda$.

Finally, by Equation (30.3) and (30.4), we have

$$\Pr\left[\sum_{i\in T} \mathsf{lis}^{[\alpha_i, a_{\beta_i}]}(\mathsf{sa}_i) \geq (1-4\epsilon)\mathsf{lis}(A)\right] \geq 1 - \exp(-\Omega(\epsilon^2\sqrt{n}\lambda)).$$

□

30.4.2 Constructing Approximately Optimal Pseudo-solutions

We call a sequence of $\sqrt{n}$ intervals $[\ell_1, r_1], [\ell_2, r_2], \ldots, [\ell_{\sqrt{n}}, r_{\sqrt{n}}]$ a pseudo-solution if all of the intervals are monotone. That is $\ell_1 \leq r_1 < \ell_2 \leq r_2 < \ell_3 \leq r_3 \leq \ldots \leq \ell_{\sqrt{n}} \leq r_{\sqrt{n}}$. These intervals denote solution-domains for the subarrays. We also may decide not assign any solution domain to a subarray in which case we show the corresponding interval by $\emptyset$. Indeed, $\emptyset$ does not break the monotonicity of a pseudo-solution. The quality of a pseudo-solution is defined as $\sum_i \mathsf{lis}^{[\ell_i, r_i]}(\mathsf{sa}_i)$. We denote the quality of a pseudo-solution ps by $\mathsf{q}(\mathsf{ps})$.

Another way to interpret Corollary 30.4.2 is that one can construct a pseudo-solution using the sampled elements whose quality is at least a $1-\epsilon$ fraction of $\mathsf{lis}(A)$. In this section, we present an algorithm to construct a small set of pseudo-solutions with the promise that at least one of them has a quality of at least $\mathsf{lis}(A)/t$, where t is the number of pseudo-solutions. Finally, in Section 30.4.3, we present a method to approximate the size of the optimal solution using pseudo-solutions.

We construct the pseudo-solutions via Algorithm 30.5. The input of Algorithm 30.5 is the set of candidate domain intervals obtained by Algorithm 30.4 on every subarray. We first find an assignment of candidate solution domains to the subarrays which is monotone and has the largest number of candidate domain intervals. (This step can be implemented by dynamic programming.) We make a pseudo-solution out of this assignment and update the set of candidate intervals by removing the ones which are used in our pseudo-solution. We then repeat the same procedure to construct the second pseudo-solution and update the candidate solution domains accordingly. We continue on, until the number of solution domains used in our pseudo-solution drops below $\epsilon\sqrt{n}$ in which case we stop.

We first prove in Lemma 30.4.3 that the number of pseudo-solutions constructed in Algorithm 30.5 is bounded by $O(k^2/(\lambda\epsilon))$. Next, we show in Lemma 30.4.4 that at least one of the pseudo-solutions constructed by Algorithm 30.5 has a quality of at least $\Omega(\mathsf{lis}(A)/t)$ where t is the number of pseudo-solutions. Finally we prove in Lemma 30.4.5 that the running time of Algorithm 30.5 is $O(tk^2\sqrt{n}\log n)$.

Lemma 30.4.3 (number of pseudo-solutions)**.** *For each $i \in [\sqrt{n}]$, let cdi_i be a set of at most k^2 candidate domain intervals. Let t denote the number of pseudo-solutions constructed in Algorithm 30.5. Then, we have $t \leq k^2/(\lambda\epsilon)$.*

Proof. Note that for each subarray we have at most k^2 candidate domain intervals. Since there are $\sqrt{n}$ subarrays, then in total we have $\sqrt{n}k^2$ candidate domain intervals. Each time we construct a pseudo-solution, the total number of the candidate domain intervals is decreased by at least $\epsilon\sqrt{n}\lambda$. Thus, the total number of pseudo-solutions t can be upper bounded,

$$t \leq \frac{\sqrt{n}k^2}{\epsilon\sqrt{n}\lambda} \leq \frac{k^2}{\lambda\epsilon}.$$

□

Lemma 30.4.4 (quality of pseudo-solutions)**.** *Let* $\mathsf{ps}_1, \mathsf{ps}_2, \ldots, \mathsf{ps}_t$ *be the pseudo-solutions constructed by Algorithm 30.5. If* $\mathsf{lis}(A) \geq n\lambda$ *holds, then with probability at least* $1 - \exp(-\Omega(\sqrt{n}\lambda))$*, there exists an* $i \in [t]$ *such that*

$$\mathsf{q}(\mathsf{ps}_i) \geq \frac{\mathsf{lis}(A)}{2t}.$$

Proof. Let us focus again on the actual solution domains

$$[\mathsf{sm}(\mathsf{sa}_1), \mathsf{lg}(\mathsf{sa}_1)], [\mathsf{sm}(\mathsf{sa}_2), \mathsf{lg}(\mathsf{sa}_2)], \ldots, [\mathsf{sm}(\mathsf{sa}_{\sqrt{n}}), \mathsf{lg}(\mathsf{sa}_{\sqrt{n}})].$$

We define set $S \subseteq [\sqrt{n}]$ such that

$$\mathsf{lis}^{[\mathsf{sm}(\mathsf{sa}_i), \mathsf{lg}(\mathsf{sa}_i)]} \geq \epsilon\sqrt{n}\lambda, \forall i \in S.$$

Using Corollary 30.4.2 with $\epsilon = 1/10$, we know that there is a monotone pseudo-solution $[\alpha_i, \beta_i]_{i \in T}$ ($T \subseteq S$) such that $[\alpha_i, \beta_i]$ are candidate domain intervals and

$$\sum_{i \in T} \mathsf{lis}^{[\alpha_i, \beta_i]}(\mathsf{sa}_i) \geq (1 - 4\epsilon)\mathsf{lis}(A).$$

Denote this pseudo-solution as sol.

At the time we terminate Algorithm 30.5, there are at most $\epsilon\sqrt{n}\lambda$ candidate domain intervals of sol does not belongs to any pseudo-solution of the pseudo-solution set. Also, since each candidate domain interval contributes at most $\sqrt{n}$ to the quality of the pseudo-solution containing the interval, we have

$$\sum_{i=1}^{t} \mathsf{q}(\mathsf{ps}_i) \geq (1-4\epsilon)\mathsf{lis}(A) - \epsilon\sqrt{n}\lambda \cdot \sqrt{n} \geq (1-4\epsilon)\mathsf{lis}(A) - \epsilon\mathsf{lis}(A) = (1-5\epsilon)\mathsf{lis}(A).$$

Thus, there exists an $i \in [t]$ such that

$$\mathsf{q}(\mathsf{ps}_i) \geq (1-5\epsilon)\mathsf{lis}(A)/t = \mathsf{lis}(A)/(2t).$$

□

Lemma 30.4.5 (running time)**.** *For each $i \in [\sqrt{n}]$, let cdi_i be a set of at most k^2 candidate domain intervals. Let t denote the number of pseudo-solutions. The running time of Algorithm 30.5 is bounded by $O(tk^2\sqrt{n}\log n)$.*

Proof. Lemma 30.4.3 states that Algorithm 30.5 terminates after constructing t pseudo-solutions.

Now we show that constructing each pseudo-solution takes time $O(k^2\sqrt{n}\log n)$. Our solution is based on a dynamic programming technique. Let $D : [\sqrt{n}] \times [k^2] \to \mathbb{N}$ be an array such that $D[i][j]$ stores the size of the largest monotone pseudo-solution for the first i subarrays which ends with the j'th candidate domain interval of sa_i. Using classic segment-tree data structure (this data structure can be found in many textbooks, e.g. [CLRS09]), one can compute the value of $D[i][j]$ in time $O(\log n)$ from the previously computed elements of the array.

Thus, the total running is bounded by $O(tk^2\sqrt{n}\log n)$. □

30.4.3 Evaluating the Pseudo-solutions

We finally use a concentration bound to show that the quality of a pseudo-solution can be approximated well by sampling a small number of subarrays. Since a pseudo-solution specifies the range of the numbers used in every subarray, the quality of a pseudo-solution, or in other words, the size of the corresponding increasing subsequence of a pseudo-solution can be formulated as

$$\mathsf{q}(\mathsf{ps}) = \sum_{i=1}^{\sqrt{n}} \mathsf{lis}^{[\ell_i, r_i]}(\mathsf{sa}_i)$$

where $[\ell_i, r_i]$ denotes the corresponding solution domain of ps for sa_i.

In Lemma 30.4.6, we prove that by sampling $O(\log^{O(1)} n/\lambda^4)$ many subarrays and computing $\mathsf{lis}^{[\ell_i, r_i]}(\mathsf{sa}_i)$ for them, one can approximate the quality of a pseudo-solution pretty accurately.

Lemma 30.4.6 (the quality of pseudo-solution)**.** *Let $\lambda \in (0,1)$ and ϵ be a constant in $(0, 1/100)$. Let $\mathsf{ps}_1, \mathsf{ps}_2, \cdots, \mathsf{ps}_t$ be a set of t pseudo-solutions. With probability at least $1 - \exp(-\Omega(\log^2 n))$, Algorithm 30.6 runs in time $O(t^2\sqrt{n}\log^{O(1)} n/\lambda)$ such that ,*

1. *If there exists an $i \in [t]$, $\mathsf{q}(\mathsf{ps}_i) \geq \frac{\lambda n}{2t}$, then the algorithm outputs an estimation at least $\frac{\lambda n}{4t}$.*
2. *If $\mathsf{q}(\mathsf{ps}_i) < \frac{\lambda n}{8t}$ for al the $i \in [t]$, then the algorithm outputs an estimation smaller than $\frac{\lambda n}{4t}$.*

Proof. By Chernoff bound, with probability $1 - \exp(-\Omega(\log^3 n))$ most $2p\sqrt{n} = \frac{2000t\log^4 n}{\epsilon^4\lambda}$ subarrays are sampled. For each pseudo-solution, Algorithm 30.6 runs the algorithm for longest increasing subsequence once for every sampled subarray. Hence, the running time of the algorithm is $O(t^2\sqrt{n}\log^{O(1)} n/\lambda)$.

Consider an arbitrary pseudo-solution $\mathsf{ps} \in \{\mathsf{ps}_1, \ldots, \mathsf{ps}_t\}$ for now. We show that

$$\Pr\left[\left(1-\frac{\epsilon}{4}\right)^2\left(\mathsf{q}(\mathsf{ps}) - \frac{\epsilon\lambda^4 n}{100t}\right)\widetilde{\mathsf{q}}(\mathsf{ps}) \le \left(1+\frac{\epsilon}{4}\right)^2\mathsf{q}(\mathsf{ps}) + \frac{\epsilon\lambda^4 n}{100t}\right] \le 1 - \exp(-\Omega(\log^3 n)).$$

Then the lemma holds by a union bound on all the pseudo-solutions.

Let T be the set of subarray indices such that $i \in T$ iff there is a non-empty interval $[\ell_i, r_i]$ of ps corresponding to subarray sa_i. Let $p = \frac{1000t\log^4 n}{\epsilon^4\lambda\sqrt{n}}$ be the probability of sampling a subarray. For each $i \in T$, let X_i denote a random variable such that

$$X_i = \begin{cases} 1, & \text{with prob. } p; \\ 0, & \text{with prob. } 1-p. \end{cases}$$

and

$$X = \sum_{i\in T}\frac{1}{p}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)X_i.$$

We have

$$\mathbb{E}[X] = \mathbb{E}\left[\sum_{i\in T}\frac{1}{p}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)X_i\right] = \sum_{i\in T}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i) = \mathsf{q}(\mathsf{ps}).$$

Let

$$T_j = \left\{i \in T : (1+\epsilon/4)^{j-1} \le \mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i) < (1+\epsilon/4)^j\right\}$$

for integer $1 \le j \in \left\lceil \log_{1+\epsilon}\sqrt{n}\right\rceil$.

Let $\Delta = \frac{\epsilon^2 \lambda \sqrt{n}}{1000t \log n}$. Consider T_j's such that $|T_j| \geq \Delta$. The contribution of $\mathsf{q}(\mathsf{ps})$ mostly comes from T_j in the following sense

$$\sum_{j:|T_j|\geq\Delta} \sum_{i\in T_j} \mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i) \leq \mathsf{q}(\mathsf{ps}) \tag{30.5}$$

and

$$\begin{aligned}\sum_{j:|T_j|\geq\Delta} \sum_{i\in T_j} \mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i) =& \mathsf{q}(\mathsf{ps}) - \sum_{j:|T_j|<\Delta} \sum_{i\in T_j} \mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i) \\ \geq& \mathsf{q}(\mathsf{ps}) - \Delta\sqrt{n} \cdot \left\lceil \log_{1+\epsilon} \sqrt{n} \right\rceil \\ \geq& \mathsf{q}(\mathsf{ps}) - \frac{\epsilon\lambda n}{100t}.\end{aligned} \tag{30.6}$$

Now we bound the random variable $\sum_{j:|T_j|\geq\Delta} \sum_{i\in T_j} \mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i) X_i/p$. By Chernoff bound, for each j such that $|T_j| \geq \Delta$, we have

$$\Pr\left[\left(1-\frac{\epsilon}{4}\right) p|T_j| \leq \sum_{i\in T_j} X_i \leq \left(1+\frac{\epsilon}{4}\right) p|T_j|\right] \geq 1-\exp(-\Omega(\epsilon^2 p|T_j|)) = 1-\exp(-\Omega(\log^3 n)). \tag{30.7}$$

Notice that for set T_j,

$$\frac{(1+\epsilon/4)^{j-1}}{p} \sum_{i\in T_j} X_i \leq \sum_{i\in T_j} \frac{1}{p} \mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i) X_i \leq \frac{(1+\epsilon/4)^j}{p} \sum_{i\in T_j} X_i. \tag{30.8}$$

We have

$$
\begin{aligned}
&\Pr\left[\left(1-\frac{\epsilon}{4}\right)^2\sum_{i\in T_j}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)\le\sum_{i\in T_j}\frac{1}{p}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)X_i\le\left(1+\frac{\epsilon}{4}\right)^2\sum_{i\in T_j}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)\right]\\
\ge&\Pr\left[\left(1-\frac{\epsilon}{4}\right)^2\sum_{i\in T_j}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)\le\frac{(1+\epsilon/4)^{j-1}}{p}\sum_{i\in T_j}X_i\right.\\
&\qquad\left.\bigwedge\frac{(1+\epsilon/4)^{j}}{p}\sum_{i\in T_j}X_i\le\left(1+\frac{\epsilon}{4}\right)^2\sum_{i\in T_j}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)\right]\\
\ge&\Pr\left[\left(1-\frac{\epsilon}{4}\right)^2\left(1+\frac{\epsilon}{4}\right)^j|T_j|\le\frac{(1+\epsilon/4)^{j-1}}{p}\sum_{i\in T_j}X_i\right.\\
&\qquad\left.\bigwedge\ \frac{(1+\epsilon/4)^{j}}{p}\sum_{i\in T_j}X_i\le\left(1+\frac{\epsilon}{4}\right)^{j+1}|T_j|\right]\\
\ge&\Pr\left[\left(1-\frac{\epsilon}{4}\right)p|T_j|\le\sum_{i\in T_j}X_i\ \bigwedge\ \sum_{i\in T_j}X_i\le\left(1+\frac{\epsilon}{4}\right)p|T_j|\right]\\
=&1-\exp(-\Omega(\log^3 n)),
\end{aligned}
\tag{30.9}
$$

where the first inequality follows from Equation (30.8), the second inequality follows from the definition of T_j and the last inequality follows from Equation (30.7). By Equation (30.5),

(30.6), (30.10) and union bound, we have

$$\begin{aligned}
&\Pr\left[\left(1-\frac{\epsilon}{4}\right)^2\left(\mathsf{q}(\mathsf{ps})-\frac{\epsilon\lambda n}{100t}\right)\le\sum_{j:|T_j|\ge\Delta}\sum_{i\in T_j}\frac{1}{p}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)X_i\le\left(1+\frac{\epsilon}{4}\right)^2\mathsf{q}(\mathsf{ps})\right]\\
\ge&\Pr\left[\left(1-\frac{\epsilon}{4}\right)^2\sum_{j:|T_j|\ge\Delta}\sum_{i\in T_j}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)\le\sum_{j:|T_j|\ge\Delta}\sum_{i\in T_j}\frac{1}{p}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)X_i\right.\\
&\qquad\left.\le\sum_{j:|T_j|\ge\Delta}\left(1+\frac{\epsilon}{4}\right)^2\sum_{i\in T_j}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)\right]\\
\ge&1-O\left(\frac{\log n}{\epsilon}\right)\exp(-\Omega(\log^3 n))\\
=&1-\exp(-\Omega(\log^3 n)).
\end{aligned}\tag{30.10}$$

Now we bound random variable $\sum_{j:|T_j|<\Delta}\sum_{i\in T_j}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)X_i/p$. If $|T_j|<\Delta$, then by Chernoff bound we have

$$\Pr\left[\sum_{i\in T_j}X_i\le\frac{2\log^3 n}{\epsilon^2}\right]\ge 1-\exp(-\Omega(\log^3 n)).$$

By union bound we have

$$\Pr\left[\sum_{j:|T_j|<\Delta}\sum_{i\in T_j}\frac{1}{p}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)X_i\le\frac{2\log^3 n}{\epsilon^2}\cdot\frac{\sqrt{n}}{p}\cdot\left\lceil\log_{1+\epsilon}\sqrt{n}\right\rceil<\frac{\epsilon\lambda n}{100t}\right]\ge 1-\exp(-\Omega(\log^3 n))).\tag{30.11}$$

If $\mathsf{q}(\mathsf{ps})\ge\frac{\lambda n}{2t}$, then then by Equation (30.10)

$$\begin{aligned}
&\Pr\left[X>\frac{\lambda n}{4t}\right]\\
\ge&\Pr\left[\left(1-\frac{\epsilon}{4}\right)^2\left(\mathsf{q}(\mathsf{ps})-\frac{\epsilon\lambda n}{100t}\right)\le\sum_{j:|T_j|\ge\Delta}\sum_{i\in T_j}\frac{1}{p}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)X_i\right]\\
\ge&1-\exp(-\Omega(\log^3 n)).
\end{aligned}$$

If $\mathsf{q}(\mathsf{ps}) < \frac{\lambda n}{8t}$, then by Equation (30.10) and Equation (30.11),

$$\begin{aligned}
&\Pr\left[X < \frac{\lambda n}{4t}\right] \\
\geq &\Pr\left[\sum_{j:|T_j|\geq\Delta}\sum_{i\in T_j}\frac{1}{p}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)X_i \leq \left(1+\frac{\epsilon}{4}\right)^2\mathsf{q}(\mathsf{ps}) \bigwedge \sum_{j:|T_j|<\Delta}\sum_{i\in T_j}\frac{1}{p}\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i)X_i \leq \frac{\epsilon\lambda n}{100t}\right] \\
\geq &1-\exp(-\Omega(\log^3 n)).
\end{aligned}$$

□

Putting all the previous Lemmas together gives the following result:

Corollary 30.4.7 (algorithm for LIS decision problem)**.** *Given a length-n sequence A, let $\lambda \in [1/n, 1]$. There is a randomized algorithm that runs in time $O(\lambda^{-7}\sqrt{n}\log^{O(1)} n)$ such that with probability $1 - 1/\operatorname{poly}(n)$*

- *The algorithm accepts if $\mathsf{lis}(A) > n\lambda$.*
- *The algorithm rejects if $\mathsf{lis}(A) = O(n\lambda^4)$.*

Proof. The correctness follows from Lemma 30.4.6, Lemma 30.4.4, and Lemma 30.4.5.

Running time: The running time is

$$\begin{aligned}
\text{time} &= \underbrace{O(tk^2\sqrt{n}\log^{O(1)} n)}_{\text{Lemma 30.4.5}} + \underbrace{O(t^2\lambda^{-1}\sqrt{n}\log^{O(1)} n)}_{\text{Lemma 30.4.6}} \\
&= O(t^2\lambda^{-1}\sqrt{n}\log^{O(1)} n) && \text{by Lemma 30.4.3} \\
&= O(k^4\lambda^{-3}\sqrt{n}\log^{O(1)} n) && \text{by Lemma 30.4.3} \\
&= O(\lambda^{-7}\sqrt{n}\log^{O(1)} n)
\end{aligned}$$

Thus, we complete the proof. □

Finally, by starting with $\lambda = 1$ and iteratively multiplying λ by a $1/(1+\epsilon)$ factor until a solution is found, we can approximate $\mathsf{lis}(A)$ within an approximation factor of $O(\lambda^3)$.

Theorem 30.4.8 (polynomial approximation for LIS)**.** *Given a length-n sequence A such that $\mathsf{lis}(A) = n\lambda$ where $\lambda \in [1/n, 1]$ is unknown to the algorithm. There is an algorithm that runs in time $\widetilde{O}(\lambda^{-7}\sqrt{n})$ and outputs a number est such that*

$$\Omega(\mathsf{lis}(A)\lambda^3) \leq \mathsf{est} \leq O(\mathsf{lis}(A)).$$

with probability at least $1 - 1/\operatorname{poly}(n)$.

We remark that one can turn Theorem 30.4.8 into an algorithm with running time $\widetilde{O}(n^{17/20})$ by considering two cases separately. If $\lambda < n^{-1/20}$ we sample the array with a rate of $n^{-3/20}$ and compute the LIS for the sampled array. Otherwise, the running time of the algorithm is already bounded by $\widetilde{O}(n^{17/20})$.

30.4.4 An $O(n^\kappa)$ Time Algorithm via Bootstrapping

Let us move a step backward and analyze the previous algorithm for obtaining an $O(\lambda^3)$ approximate solution. We first divide the input array into $\sqrt{n}$ subarrays of size $\sqrt{n}$ and after constructing the pseudo-solutions, we sample $O(\lambda^4)$ subarrays to estimate the size of the solution for pseudo-solutions. The reason we set the size of the subarrays to $\sqrt{n}$ is that there is a trade-off between the first and the last steps of the algorithm. More precisely, if we have more than $\sqrt{n}$ subarrays then the number of samples we draw in the beginning would exceed $O_\lambda(\sqrt{n})$. On the other hand, having fewer than $\sqrt{n}$ subarrays results in larger subarrays which would be costly in the last step.

If one favors the running time over the approximation factor, the following improvement can be applied to the algorithm: In the last step of the algorithm, instead of sampling the entire subarrays and computing lis for every pseudo-solution, we recursively call the same procedure to approximate the size of the solution for each subarray. This way, having large subarrays would no longer be an issue and therefore we can have fewer subarrays to improve the number of samples we draw in the first step of the algorithm.

More formally, in order to obtain a running time of $O(\text{poly}(\lambda)n^{\kappa})$ we set the size of each subarray to $n^{1-\kappa}$ and therefore after constructing the pseudo-solutions, the problem boils down to approximating the solution for $\text{poly}(\lambda)$ many subarrays of length $n^{1-\kappa}$. By running the same algorithm, we would have n^{κ} subarrays of length $n^{1-2\kappa}$ in the second iteration. After $1/\kappa - 1$ iterations, the subarrays are small enough and we can access all their elements in time $O(\text{poly}(\lambda)n^{\kappa})$. Of course, this imposes a factor of $\text{poly}(\lambda)$ to the approximation.

By generalizing the ideas from previous subsections, we show that if there is an algorithm for LIS with approximation factor $f(\lambda)$, then we can get a $\left(f\left(\frac{\lambda^4}{2^{32}}\right) \cdot \frac{\lambda^4}{2^{33}}\right)$-approximate LIS algorithm with better running time using the $f(\lambda)$-approximate algorithm as a subroutine.

Lemma 30.4.9. *Assume we partition the sequence into ζ subarrays, where ζ is polynomially related to the length of the input sequence. For parameter $\lambda \in (0,1)$, let* Oracle *be a $f(\lambda)$-approximate LIS algorithm (with respect to a domain interval) with running time $g(n,\lambda)$ and success probability $1 - \exp(-\Omega(\log^2 n))$ where n is the length of the input sequence. Then Algorithm 30.7 using* Oracle *as a subroutine is a $\left(f\left(\frac{\lambda^4}{2^{32}}\right) \cdot \frac{\lambda^4}{2^{33}}\right)$-approximate LIS algorithm*

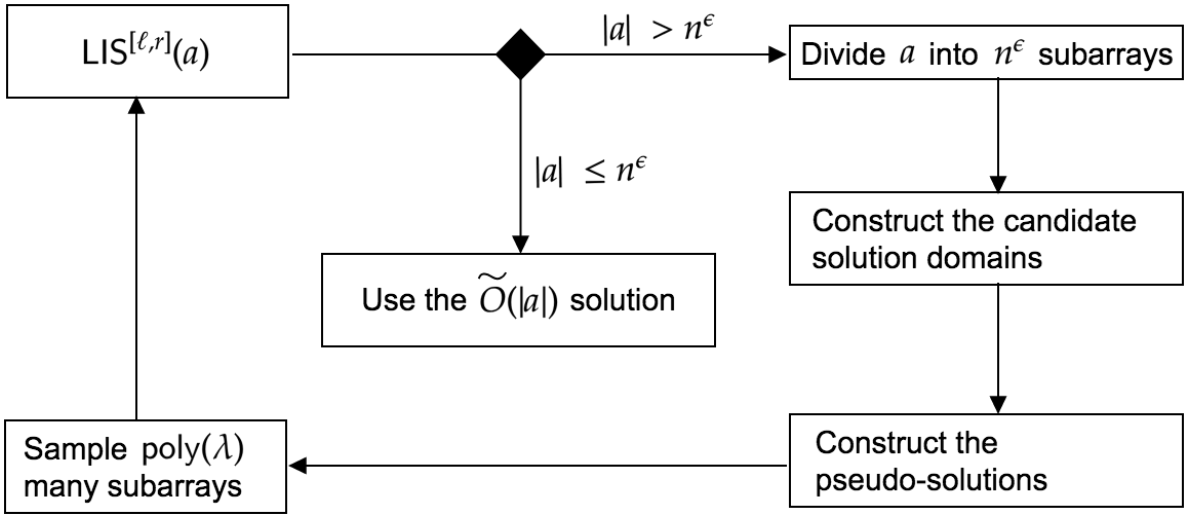

Figure 30.6: The flowchart of the $O_\lambda(n^\epsilon)$ time algorithm is shown.

with

$$O\left(\lambda^{-4} g\left(\frac{n}{\zeta}, \frac{\lambda^4}{2^{32}}\right) \log^{O(1)} n + \lambda^{-7}\zeta \log^{O(1)} n\right)$$

running time and success probability $1-\exp(-\Omega(\log^2 n))$*, where* ζ *is the number of subarrays.*

Proof. We first prove the correctness of the algorithm. Let A be a sequence of length n, and $\mathsf{sa}_1, \ldots, \mathsf{sa}_\zeta$ be the subarrays.

Consider the case of $\mathsf{lis}^{[\ell,r]}(A) \geq \lambda n$. By Corollary 30.4.2 and Lemma 30.4.4 with $\epsilon = \delta = 1/10$, with probability $1 - \exp(-\Omega(\zeta\lambda))$, there exists a pseudo-solution ps_j within interval $[\ell, r]$ satisfying

$$\mathsf{q}(\mathsf{ps}_j) \geq \frac{\mathsf{lis}^{[\ell,r]}(A)}{2t} \geq \frac{\mathsf{lis}^{[\ell,r]}(A)\lambda\epsilon}{2k^2} \geq \frac{\mathsf{lis}^{[\ell,r]}(A)\lambda\epsilon}{2 \cdot 20^2 \log^2(1/\delta)/(\lambda^2\epsilon^4)} \geq \frac{\epsilon^5\lambda^4}{800\log^2(1/\delta)} n \geq \frac{\lambda^4}{2^{31}} n.$$

Let α denote the number of subarrays sa_i such that $\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i) \geq \lambda_0 n/\zeta$ where $[\ell_i, r_i]$ is the

interval for subarray sa_i in ps_j. We have

$$\alpha \geq \frac{\mathsf{q}(\mathsf{ps}_j) - \lambda^4 n/2^{32}}{n/\zeta} \geq \frac{\lambda^4 \zeta}{2^{32}}.$$

By Chernoff bound, Step 14 to Step 22 of Algorithm 30.7 accepts on ps_j with probability at least $1 - \exp(-\Omega(\log^2 n))$.

Consider the case of

$$\mathsf{lis}^{[\ell,r]}(A) \leq f\left(\frac{\lambda^4}{2^{32}}\right)\frac{\lambda^4}{2^{33}}n.$$

Then for any pseudo-solution ps_j, we have

$$\mathsf{q}(\mathsf{ps}_j) \leq f\left(\frac{\lambda^4}{2^{32}}\right)\frac{\lambda^4}{2^{33}}n.$$

Let β denote the number of subarrays sa_i such that $\mathsf{lis}^{[\ell_i,r_i]}(\mathsf{sa}_i) \geq f(\lambda^4/2^{32})n/\zeta$ where $[\ell_i, r_i]$ is the interval for subarray sa_i in ps_j. We have

$$\beta \leq \frac{\mathsf{q}(\mathsf{ps}_j)}{f(\lambda^4/2^{32})n/\zeta} \leq \frac{\lambda^4}{2^{33}}\zeta.$$

By Chernoff bound, Step 14 to Step 22 of Algorithm 30.7 do not accept on ps_j with probability at least $1 - \exp(-\Omega(\log^2 n))$. By union bound, Algorithm 30.7 rejects with probability at least $1 - \exp(-\Omega(\log^2 n))$.

Hence, Algorithm 30.7 is a $\left(f\left(\frac{\lambda^4}{2^{32}}\right) \cdot \frac{\lambda^4}{2^{33}}\right)$-approximate algorithm for LIS of length n with success probability at least $1 - \exp(-\Omega(\log^2 n))$.

Finally, we discuss the running time of Algorithm 30.7. By the definition of procedures ConstructCandidateDomains and ConstructPseudoSolutions, the running time of Step 5 to Step 9 of Algorithm 30.7 is $O(\lambda^{-9}\zeta \log^{O(1)} n)$. By Lemma 30.4.3, $t = O(\lambda^{-3})$, and by Chernoff bound with probability $1 - \exp(-\Omega(\log^2 n))$ the size of Q is

at most $O(\lambda^{-4}\log^4 n)$. Hence, the running time of Step 12 to Step 24 of Algorithm 30.7 is $O(\lambda^{-7}g(n/\zeta, \lambda^4/2^{32})\log^4 n)$. □

By definition, we have the following basic fact about approximate ratio.

Fact 30.4.10. *Let f and f' be two functions mapping $(0,1)$ to $(0,1)$ such that $f(\lambda) \geq f'(\lambda)$ for any $\lambda \in (0,1)$. If there is a $f(\lambda)$-approximate LIS algorithm, then the algorithm is also $f'(\lambda)$-approximate.*

Now we present algorithm to approximate LIS using $\widetilde{O}(n^\kappa \operatorname{poly}(\lambda^{-1}))$ space by applying the pseudo-solution construction-evaluation framework recursively. In particular, we use the same algorithm on subarrays as an oracle and apply Lemma 30.4.9 recursively to approximate the entire sequence with slightly worse approximation ratio (compared with approximation ratio of the oracle).

Lemma 30.4.11. *Let κ be a constant of $(0,1)$ and $\lambda \in (0,1)$. Algorithm 30.8 approximates LIS with approximation ratio*

$$\frac{\lambda^{2\cdot 4^{(\lceil 1/\kappa \rceil - 1)}}}{256^{3\cdot 4^{(\lceil 1/\kappa \rceil - 1)}}}$$

and running time $O(n^\kappa \cdot \lambda^{-4^{O(1/\kappa)}} \log^{O(1)} n)$ and success probability $1 - \exp(-\Omega(\log^3 n))$.

Proof. We first prove the correctness of the algorithm by induction. Without loss of generality, we assume $1/\kappa$ is an integer.

For $i \in \{2, 3, \ldots, 1/\kappa\}$, denote

$$h_i(\lambda) = \frac{\lambda^{2\cdot 4^{(i-1)}-4}}{256^{2\cdot 4^{(i-1)}+3\cdot 4^{(i-2)}-7}}.$$

We show that if the length of the input sequence is $n^{i\cdot\kappa}$ then Algorithm 30.8 is $h_i(\lambda)$-approximate.

If the length of input sequence is $n^{2\kappa}$, then $h_2(\lambda) = \frac{\lambda^4}{2^{32}}$. By Corollary 30.4.2, Lemma 30.4.4, and Lemma 30.4.6, Algorithm 30.8 is $h_2(\lambda)$-approximate.

In the induction step, for an integer $2 \leq i < 1/\kappa$, we assume Algorithm 30.8 is $h_i(\lambda)$-approximate for input instance of length $n^{i\cdot\kappa}$. By Lemma 30.4.9, Algorithm 30.8 is $\left(h_i\left(\frac{\lambda^4}{2^{32}}\right)\frac{\lambda^4}{2^{33}}\right)$-approximate for input instance of length $n^{(i+1)\cdot\kappa}$. Since

$$\begin{aligned}
h_i\left(\frac{\lambda^4}{2^{32}}\right)\frac{\lambda^4}{2^{33}} =& \frac{\lambda^{4\cdot(2\cdot 4^{(i-1)}-4)}\cdot\lambda^4}{256^{4\cdot(2\cdot 4^{(i-1)}-4)}\cdot 256^{2\cdot 4^{(i-1)}+3\cdot 4^{(i-2)}-7}\cdot 2^{33}} \\
=& \frac{\lambda^{2\cdot 4^i-12}}{256^{2\cdot 4^i+2\cdot 4^{(i-1)}+3\cdot 4^{(i-2)}-18.875}} \\
>& \frac{\lambda^{2\cdot 4^i-4}}{256^{2\cdot 4^i+3\cdot 4^{(i-1)}-7}} \\
=& h_{i+1}(\lambda),
\end{aligned}$$

by Fact 30.4.10, Algorithm 30.8 is $h_{i+1}(\lambda)$-approximate for input instance of length $n^{(i+1)\cdot\kappa}$. Since

$$h_{1/\kappa}(\lambda) > \frac{\lambda^{2\cdot 4^{((1/\kappa)-1)}}}{256^{3\cdot 4^{((1/\kappa)-1)}}},$$

by Fact 30.4.10, Algorithm 30.8 is $\left(\frac{\lambda^{2\cdot 4^{((1/\kappa)-1)}}}{256^{3\cdot 4^{((1/\kappa)-1)}}}\right)$-approximate for input instance of length n.

By Corollary 30.4.2, Lemma 30.4.4, Lemma 30.4.6 and Lemma 30.4.9, we have the desired running time. The success probability is obtained by same corollaries/lemmas and union bound. □

Finally, by starting with $\lambda = 1$ and iteratively multiplying λ by a $1/(1+\epsilon)$ factor until a solution is found, we can approximate $\mathsf{lis}(A)$ within an approximation factor of $\lambda^{O(4^{1/\kappa})}$.

Theorem 30.4.12. *Let κ be a constant of $(0,1)$ and $\lambda \in (0,1)$. There exists a $\widetilde{O}(n^{\kappa} \cdot \lambda^{-4^{O(1/\kappa)}})$ time algorithm for lis with approximation factor $\lambda^{4^{O(1/\kappa)}}$ and success probability $1 - \exp(-\Omega(\log^3 n))$.*

30.5 Probability and Graph Tools

In this section, we restate probability and graph tools that we use throughout this paper. All these theorems are proven in previous work.

Theorem 30.5.1 (Chernoff Bounds)**.** *Let $X = \sum_{i=1}^{n} X_i$, where $X_i = 1$ with probability p_i and $X_i = 0$ with probability $1 - p_i$, and all X_i are independent. Let $\mu = \mathbb{E}[X] = \sum_{i=1}^{n} p_i$. Then*

1. $\Pr[X \geq (1+\delta)\mu] \leq \exp(-\delta^2\mu/3)$, $\forall \delta > 0$;

2. $\Pr[X \leq (1-\delta)\mu] \leq \exp(-\delta^2\mu/2)$, $\forall 0 < \delta < 1$.

Theorem 30.5.2 (Hoeffding bound)**.** *Let $X_1, \cdots, X_n$ denote n independent bounded variables in $[a_i, b_i]$. Let $X = \sum_{i=1}^{n} X_i$, then we have*

30.6 LCS Step 0: Window-compatible Solutions

The goal of this section is to show window-compatible solutions provide very accurate estimates for LCS. Roughly speaking, in this section, we construct a set of windows for A and a set of windows for B and we show that it suffices to only compute the LCS of the windows. If that information is available, then we can estimate the LCS of two strings very accurately.

We use the same definition of window-compatible transformation as [BEG+18], but we will use a richer set of windows. Every window is essentially a substring of each string. Notice that windows may not have the same length. We use W_A to denote the set of windows constructed for A and W_B for the set of the windows that we construct for B.

Let us first state our definition of window-compatible solutions for LCS.

Definition 30.6.1 (Window-compatible LCS)**.** Let $S = \langle w_1, w_2, \cdots, w_\alpha \rangle$ and $S' = \langle w'_1, w'_2, \cdots w'_\alpha \rangle$ be two sequences of non-overlapping windows from W_1 and W_2, respectively.

- We call a *common substring* of (A, B) *window-compatible* with respect to S and S', if it is a union of k common substrings of $(w_1, w'_1), \ldots, (w_\alpha, w'_\alpha)$

We call a common substring window-compatible, if it is window-compatible with respect to at least a pair of sequence of non-overlapping windows from W_1 and W_2, respectively.

30.6.1 Construction of the Windows

This section presents a definition (see Definition 30.6.2) of a multiple layers window set for strings A and B. The construction is the same for both strings, therefore, we only

state it for A. As mentioned earlier, each window is a substring of the strings. For clarity, we use $A^{(j,l)}$ to denote a length-l substring of A which starts at index j and ends at index $j+l-1$. Our construction has multiple layers, each of which contains windows with equal lengths.

Given two length n strings A, B, and two parameters $1 \leq d \leq n$ and $\epsilon_0 \in (0,1)$, we define window set W_A to be a set of continuous subsequence of string A. The sizes of the windows depend on parameter d and the accuracy of our construction depends on parameter ϵ. Setting $d = n^x$ leads to a truly subquadratic time solution for any $0 < x < 1$, however, one can play with the value of d to optimize the running time.

Our construction has multiple layers, where in each layer the lengths of the windows are the same. Let $f = \Theta(\frac{1}{\epsilon_0} \log \frac{1}{\epsilon_0})$ and $f+1$ denote the number of different layers of windows in W_A.

For each $i \in \{0, 1, \cdots, f\}$, we define $d_i = d(1+\epsilon_0)^i$, $g_i = \epsilon_0 d_i$, and $t_i = n/d_i$. For each i, let W_A^i denote the set of all the windows in this layer. We consider window set W_A^i, in i-th layer, all the window have the same size which is d_i; g_i is the shift size, it means for each window (except the leftmost and rightmost one), if we shift either to the left or to the right, it becomes another window in W_A^i.

Formally speaking, we define W_A^i as follows

Definition 30.6.2. Let W_A be the set of windows we construct for string A. Then we have

$$W_A^i = \left\{ A^{(\text{left},\text{len})} \;\middle|\; \text{left} = x \cdot g_i + y \cdot d_i, \text{len} = d_i, \forall x \in \{0, 1, \cdots, d_i/g_i - 1\}, \forall y \in \{0, 1, \cdots, t_i - 1\} \right\}$$

where we use $A^{(\text{left},\text{len})}$ denotes a continuous subsequence of string A that starts at left and

has length len. Finally W_A is $\cup_{i\in\{0,1,\cdots,f\}} W_A^i$. Similarly, for each $i \in \{0, 1, \cdots, f\}$, we can obtain W_B^i and W_B.

Indeed, the running time of constructing the windows is truly subquadratic.

Lemma 30.6.1 (Generating (d, ϵ_0)-multiple layers window set)**.** *Given two strings A, B of n symbols over Σ symbols, and parameters $d \geq 1, \epsilon_0 \in (0, 1)$. Let set W_A and W_B be generated by procedure* GenerateMultipleLevels *(Algorithm 30.9). The algorithm takes $n \cdot \widetilde{O}(1/\epsilon_0^2)$ time and $|W_A| = |W_B| = O(n/(d\epsilon_0^2))$.*

Proof. Given two sets of blocks W_A and W_B, for each block $A^{(j_1,l_1)} \in W_A$, $A^{(j_1,l_1)}$ starts at j_1 and has length l_1. Similarly, for each block $B^{(j_2,l_2)} \in W_B$, $B^{(j_2,l_2)}$ starts at j_2 and has length l_2.

We can compute

$$\sum_{i=0}^{f} t_i = n \sum_{i=0}^{f} 1/d_i = (n/d) \sum_{i=0}^{f} (1+\epsilon_0)^{-i} \leq 2n/(d\epsilon_0). \tag{30.12}$$

Then we calculate the size of window set W_A,

$$\begin{aligned}
|W_A| &= \sum_{i=0}^{f} (\#\text{ shifts}) \cdot (\#\text{ windows per shift}) \\
&= \sum_{i=0}^{f} (d_i/g_i) \cdot t_i \\
&= \sum_{i=0}^{f} \frac{1}{\epsilon_0} \cdot t_i \\
&= \frac{1}{\epsilon_0} \sum_{i=0}^{f} t_i \\
&= 2n/(d\epsilon_0^2),
\end{aligned}$$

where the second step follows from definition of window set in each layer i, the third step follows from $d_i/g_i = 1/\epsilon_0$, and last step follows from Eq. (30.12).

The running time is

$$\sum_{i=0}^{f} (d_i/g_i) \cdot t_i \cdot d_i = n \sum_{i=0}^{f} (d_i/g_i) = n \sum_{i=0}^{f} 1/\epsilon_0 = \widetilde{O}(n/\epsilon_0^2).$$

□

Remark 30.6.1. In order to make sure the loss in the approximation is negligible, we use $\epsilon_0 = \epsilon\lambda$ and therefore we have

- The total number of windows is equal to $k = |W_A| + |W_B| = O((1/\lambda)^2 n/d)$.
- The maximum size of the windows is equal to $\mathsf{w}_{\mathsf{max}} = O(d/\lambda)$.
- The minimum size of the windows is equal to $\mathsf{w}_{\mathsf{min}} = d$.
- The ratio of the maximum window size over the minimum window size is bounded by $\mathsf{w}_{\mathsf{gap}} = \mathsf{w}_{\mathsf{max}}/\mathsf{w}_{\mathsf{min}} \leq O(1/\lambda)$.
- The number of different layers which is equal to the number of different window sizes is equal to $\mathsf{w}_{\mathsf{layers}} = O((1/\lambda)\log(1/\lambda))$.

30.6.2 Optimality of the Windows

We present a structural lemma for the windows in the following. This essentially, shows that the problem of computing LCS between the two strings reduces to the problem of computing the LCS's between the windows.

Lemma 30.6.2 (Improved Structural Lemma)**.** *For any two strings A, B of length n:*

- *If $\|\operatorname{LCS}(A, B)\| \geq \lambda$, there exists a window-compatible common substring of A, B of length at least $\lambda n - 8\epsilon_0 n$ via (d, ϵ_0)-Multiple layers window (Definition 30.6.2).*

Proof. We fix d and ϵ_0.

We pick the first block $\widetilde{A}_1$ to be length d, and consider the optimal matching. Suppose the optimal matching block for $\widetilde{A}_1$ is $\widetilde{B}_1$, there are three possibilities.

First, $\widetilde{B}_1$ has length between $[\epsilon_0 d, d/\epsilon_0]$. That's good and we keep this pair.

Second, $\widetilde{B}_1$ has length at least d/ϵ_0, then we throw out this pair. The characters we throw out from $2n$ is at least d/ϵ_0, and we decrease the entire LCS by at most d.

Third, the length of $\widetilde{B}_1$ has length at most $d\epsilon_0$, then we also throw out this pair. The characters we throw out from $2n$ is at least d, and we decrease the entire LCS by at most $\epsilon_0 d$.

The above procedure can be recursively applied until we found all the matching blocks. Let's say there are k matching pairs, $(\widetilde{A}_1, \widetilde{B}_1), (\widetilde{A}_2, \widetilde{B}_2), \cdots (\widetilde{A}_\alpha, \widetilde{B}_\alpha)$. Note that $\widetilde{A}_1, \widetilde{A}_2, \cdots, \widetilde{A}_\alpha$ is a partition of A. Similarly, $\widetilde{B}_1, \widetilde{B}_2, \cdots, \widetilde{B}_\alpha$ is a partition of B. Let z_i denote the variable such that $z_i = 0$ indicates we throw out the pair, and $z_i = 1$ otherwise. Since whenever we throw out a pair, the amount of LCS got decreased is always at most ϵ_0 fraction of the characters we throw out. Since there are $2n$ characters in total. Then we LCS we decrease is at most $2\epsilon_0 n$, i.e.,

$$\sum_{i \in Z} \operatorname{LCS}(\widetilde{A}_i, \widetilde{B}_i) \geq \operatorname{LCS}(A, B) - 2\epsilon_0 n, \tag{30.13}$$

where $Z = \{i \mid z_i = 1, i \in [k]\}$.

We consider a fixed $i \in Z$. For each pair $\widetilde{A}_i, \widetilde{B}_i$, let p and q denote the integer that

$$|\widetilde{A}_i| \in ((1+\epsilon_0)^p, (1+\epsilon_0)^{p+1}], \text{ and } |\widetilde{B}_i| \in ((1+\epsilon_0)^q, (1+\epsilon_0)^{q+1}].$$

Let $\widehat{A}_i$ and $\widehat{B}_i$ denote the two pairs from W_A and W_B that has the largest LCS and satisfies the following

$$|\widehat{A}_i| = (1+\epsilon_0)^{p-1},\ \widehat{A}_i \subseteq \widetilde{A}_i,\ |\widehat{B}_i| = (1+\epsilon_0)^{q-1},\ \widehat{B}_i \subseteq \widetilde{B}_i.$$

Since $|\widetilde{A}_i| - |\widehat{A}_i| \geq (1+\epsilon_0)^p - (1+\epsilon_0)^{p-1} = \epsilon_0(1+\epsilon_0)^{p-1}$. Recall the construction of W_A, we places a length $(1+\epsilon_0)^{p-1}$ block for every $\epsilon_0(1+\epsilon_0)^{p-1}$ shifts. Thus, there must exist such block $\widehat{A}_i$ from W_A and $\widehat{A}_i \subseteq \widetilde{A}_i$. Similarly, the same argument holds for $\widehat{B}_i$.

According to the definition of W_A and W_B, we know that

$$\begin{aligned}
|\widetilde{A}_i \backslash \widehat{A}_i| &\leq (1+\epsilon_0)^{p+1} - (1+\epsilon_0)^{p-1} \\
&\leq (1+\epsilon_0)^{p-1} 3\epsilon_0 \\
&\leq 3\epsilon_0 |\widetilde{A}_i|.
\end{aligned}$$

Similarly, $|\widetilde{B}_i \backslash \widehat{B}_i| \leq 3\epsilon_0 |\widetilde{B}_i|$. The characters we ignore is at most $3\epsilon_0 \cdot \max(|\widetilde{A}_i|, |\widetilde{B}_i|)$. Let $\tau_i = 3\epsilon_0 \cdot \max(|\widetilde{A}_i|, |\widetilde{B}_i|)$, then $\tau_i \leq 3\epsilon_0(|\widetilde{A}_i| + |\widetilde{B}_i|)$.

If we consider $\sum_{i \in Z} |\operatorname{LCS}(\widehat{A}_i, \widehat{B}_i)|$,

$$\begin{aligned}
\sum_{i \in Z} |\operatorname{LCS}(\widehat{A}_i, \widehat{B}_i)| &\geq \sum_{i \in Z} (|\operatorname{LCS}(\widetilde{A}_i, \widetilde{B}_i)| - \tau_i) \\
&\geq \sum_{i \in Z} |\operatorname{LCS}(\widetilde{A}_i, \widetilde{B}_i)| - 6\epsilon_0 n \\
&\geq |\operatorname{LCS}(A, B)| - 8\epsilon_0 n,
\end{aligned}$$

where the second step follows from $\sum_{i \in Z} \tau_i \leq 6\epsilon_0 n$, the third step follows from Eq. (30.13).

□

30.6.3 Dynamic Programming for Block-based LCS

We showed in Section 30.6.2 that there always exists a window-compatible solution whose size is very close to that of the optimal solution. In this section, we show how one can find such a solution via dynamic programming. Therefore, we assume that a matrix M is provided as input that stores the LCS of every pair of windows.

Lemma 30.6.3 (Dynamic Programming for Longest Common Sequence)**.** *Given two strings A, B of length n. Let $\epsilon \in (0,1)$, $d \geq 1$. Let W_A, W_B be generated by procedure* CreateMultipleLevels *$(A, B, n, d, \Theta(\epsilon\lambda))$ (Algorithm 30.9). Let table M be generated by procedure* NonMetricEstimation *(W_A, W_B).*

Then there is an algorithm (Algorithm 30.10) that runs in $(n/d)^2 \cdot \mathrm{poly}(\lambda, 1/\epsilon)$ time to output a monotone matching between two sets W_A and W_B which gives a string C such that

$$|C| \geq (1 - o(1)) \cdot (1 - \epsilon) \cdot |\operatorname{LCS}(A, B)|.$$

Proof. We choose $\epsilon_0 = \Theta(\epsilon/\lambda)$.

Using Lemma 30.6.2, we know there exits a batch of window-pairs $(\widehat{A}_{i_1}, \widehat{B}_{j_1}), (\widehat{A}_{i_2}, \widehat{B}_{j_2}), \cdots$ from W_A, W_B such that

$$\sum_l |\operatorname{LCS}(\widehat{A}_{i_l}, \widehat{B}_{i_l})| \geq |\operatorname{LCS}(A, B)| - 8\epsilon_0 n. \tag{30.14}$$

By assumption on M, we know that M gives a good estimation for every pair in W_A, W_B :

$$\delta_{i_l,j_l} d_{i_l,j_l} \geq M_{i_l,j_l} \geq (1 - o(1))\delta_{i_l,j_l}^3 \cdot d_{i_l,j_l}.$$

where $d_{i_l,j_l} = \max\{|\widehat{A}_{i_l}|, |\widehat{B}_{j_l}|\}$, $\delta_{i_l,j_l} = |\operatorname{LCS}(\widehat{A}_{i_l}, \widehat{B}_{j_l})|/d_{i_l,j_l}$. It implies that

$$|\operatorname{LCS}(\widehat{A}_{i_l}, \widehat{B}_{j_l})| \geq M_{i_l,j_l} \geq (1 - o(1))\delta_{i_l,j_l}^2 |\operatorname{LCS}(\widehat{A}_{i_l}, \widehat{B}_{j_l})|.$$

Now, if we consider this cost $\sum_l M_{i_l,j_l}$,

$$\begin{aligned}
\sum_l M_{i_l,j_l} &\geq (1 - o(1)) \cdot \sum_l \delta_{i_l,j_l}^2 |\operatorname{LCS}(\widehat{A}_{i_l}, \widehat{B}_{j_l})| \\
&\geq (1 - o(1)) \cdot \lambda^{-2} \sum_l |\operatorname{LCS}(\widehat{A}_{i_l}, \widehat{B}_{j_l})| \\
&\geq (1 - o(1)) \cdot (|\operatorname{LCS}(A, B)| - 8\epsilon_0 n) \\
&= (1 - o(1)) \cdot (|\operatorname{LCS}(A, B)| - \epsilon n/\lambda) \\
&\geq (1 - o(1))(1 - \epsilon)|\operatorname{LCS}(A, B)|
\end{aligned}$$

where the second step follows from $\delta_{i_l,j_l} \geq \lambda^{-1}$, the third step follows from Eq. (30.14), the fourth step follows from $\epsilon_0 = \Theta(\epsilon/\lambda)$, the last step follows from $\operatorname{LCS}(A, B) \geq \lambda n$.

Next, we prove the correctness of running time. Using Lemma 30.6.1, we know that $|W_A| = |W_B| = O(n/(d\epsilon_0^2))$. Then $|S_1| = |S_2| = O(n/(d\epsilon_0^2))$. The running time of sorting takes $O(|S_1| \log |S_1|)$.

The dominated part of the running time is three for-loops. For the third one, if we consider a fixed i_1 and i_2, there are $O((\frac{1}{\epsilon_0} \log(1/\epsilon_0))^2)$ pairs could have right index at i_1, i_2. Thus the running time of dynamic programming takes

$$(n/(d\epsilon_0^2)) \cdot (n/(d\epsilon_0^2)) \cdot O\left(((1/\epsilon_0) \log(1/\epsilon_0))^2\right) = (n/d)^2 \cdot \widetilde{O}(1/\epsilon_0^6).$$

For the correctness of dynamic programming, it follows from three cases cover all the possibilities. For each i_1, i_2, we define $C[i_1][i_2]$ to be optimal solution that only uses blocks from W_A with ending index no later than i_1 and blocks from W_B with ending index no later than i_2. Suppose we are at i_1, i_2. There are three cases, the first case is, the last pair of the optimal solution for $C[i_1][i_2]$ is ending at i_1, i_2. The second case is, the last pair of the optimal solution for $C[i_1][i_2]$ is ending at $\text{prev}(i_1), i_2$. The third case is, the last pair of the optimal solution for $C[i_1][i_2]$ is ending at $i_1, \text{prev}(i_2)$. □

Remark 30.6.2. If in the above algorithm, M instead of the correct LCS's has a $(1-\epsilon)\lambda^2$ or $O(\lambda^3)$ approximation of the solutions, then the overall approximation factor of the algorithm would be $(1-\epsilon)\lambda^2$ or $O(\lambda^3)$, respectively.

30.7 LCS Step 2: Discovering the Sparse Graph

The arguments of this section follow from the work of [CDG+18]. However, for the sake of completeness, we restate the overall ideas here. This section is dedicated to presenting a method NonMetricEstimation(W_A, W_B) to be used for estimating the longest common subsequence. The output of NonMetricEstimation(W_A, W_B) is a matrix $M : [|W_A|] \times [|W_B|] \to \mathbb{Z}^+$ where $M[i][j]$ estimates the LCS of windows $w_i \in W_A$ and $w_j \in W_B$. We allow for errors in a few elements of M but we prove at the end of this section that with high probability, the error does not affect the solution significantly.

Similar to Section 30.3, we define $W = W_A \cup W_B$ and denote the windows inside W by $w_1, w_2, \ldots, w_k$. For a threshold λ the edges of graph G_λ reflect pairs of windows (w_i, w_j) such that $\|\mathsf{lcs}(w_i, w_j)\| \geq \lambda$. In order to estimate M, we need to discover the edges of G_λ for $\lambda \in \{\epsilon\lambda_0, \epsilon\lambda_0(1+\epsilon), \epsilon\lambda_0(1+\epsilon)^2, \ldots, 1\}$ and build M based on that. In other words, for each w_i and w_j, we find the largest λ such that G_λ contains edge (i, j) and set $M[i][j] = \lambda$.

Let us for simplicity fix the approximation factor to be $(1-\epsilon)\lambda^2$. As mentioned earlier, we represent the edges of G_λ by a matrix $\mathsf{O} : [k] \times [k] \to \{0, 1\}$ where $\mathsf{O}[i][j] = 1$ implies that edge (i, j) exists in G_λ. The $(1-\epsilon)\lambda^2$ sparsification gives us an output $\widehat{\mathsf{O}}_{(1-\epsilon)\lambda^2}$ where except for a few pairs the rest of the edges of G_λ are detected within an approximation factor $(1-\epsilon)\lambda^2$. If all the edges were detected with this algorithm, this would provide us with a matrix M such that $(1-\epsilon)\|\mathsf{lcs}(w_i, w_j)\|^3 \leq M[i][j] \leq \|\mathsf{lcs}(w_i, w_j)\|$ holds if $\|\mathsf{lcs}(w_i, w_j)\| \geq \epsilon\lambda$. If such a matrix is given to Algorithm 30.11, it would result in a solution with approximation factor $(1-\epsilon)\lambda^2$.

However, not all the edges of G_λ are detected in Step 1. Therefore, if we use the

discovered edges to construct a matrix $\widehat{M}$ for the LCS of the windows, $\widehat{M}$ may not meet the guarantee of M for at most $\widetilde{O}(k^{2-\Omega(1)})$ pairs. In what follows, we present an algorithm that resolves this issue.

To simplify the notation, define a graph NG in which every window is a vertex and there is an edge between pair (i, j) if the LCS of windows w_i and w_j is not estimated correctly in the sparsification step. Our algorithm is not aware of the edges of NG but since the number of remaining edges is truly subquadratic, we have $|E(\mathsf{NG})| = \widetilde{O}(k^{2-\Omega(1)})$.

Let us assume that NG contains at most $\widetilde{O}(k^{2-\eta})$ edges. This implies that the average degrees of the vertices of NG is upper bounded by $\widetilde{O}(k^{1-\eta})$. Although we are not given the edges of NG explicitly, we can verify for each pair (i, j) whether there is an edge between them in NG by computing the LCS of w_i and w_j and comparing it to the value that has been obtained in $\widehat{M}$.

Let $\mathsf{w_{max}} = \max_i |w_i|$ be the maximum length of the windows. Define two windows (w_i, w_j) of W_A or two windows (w_i, w_j) of W_B to be *nearby* if their distance is bounded by at most $\mathsf{w_{max}}k^{\eta/2}$. That is w_i covers an index a and w_j covers an index b such that $|a-b| \leq \mathsf{w_{max}}k^{\eta/2}$. We subsample a set S of W_A with a rate of $\epsilon^{-1}k^{-\eta/2}$. That is, each window of W_A appears in S independently, with probability $\epsilon^{-1}k^{-\eta/2}$. Next, for each window $w_i \in S$, we discover all of its incident edges in NG by computing the LCS of w_i and every window $w_j \in W_B$. Every time we discover one edge of NG we add this edge to NG'. Notice that NG' contains a subset of edges of NG however, the edges of NG' are known to the algorithm and are available. Finally, we update M by computing the LCS of pairs of windows (w_i, w_j) such that there exist windows $w_{i'} \in W_A$ and $W_{j'} \in W_B$ such that 1) w_i and $w_{i'}$ are nearby, 2) w_j and $w_{j'}$ are nearby, and 3) vertices i and j are neighbors in NG'. This is shown in Algorithm

30.12.

It follows from the analysis of [CDG+18] that if we use M as an estimation of the windows, then Algorithm 30.11 finds the desired solution even though M does not correctly estimate all the values.

Lemma 30.7.1 ([CDG+18])**.** *Let $\widehat{M}$ be the output of the sparsification algorithm and M be constructed by Algorithm 30.12 from $\widehat{M}$. If NG has at most $\widetilde{O}(k^{2-\eta})$ edges, then the runtime of Algorithm 30.12 is bounded by $\widetilde{O}\left(k^{2-\eta/2}\mathsf{w}_{\mathsf{max}}^2/\lambda^4\right)$. Also using M as an estimate for the LCS of the windows hurts the solution by a factor of at most $1+\epsilon$.*

Proof. The proof follow from the arguments of [CDG+18]. Here we just mention the intuition and the overall ideas.

Runtime: Since every window of W_A is sampled with probability $k^{-\eta/2}$ the size of S is bounded by $O(k^{1-\eta/2})$ with high probability. In order to discover the incident edges of set S in NG, we compute the LCS of every element in S and all other windows. Therefore, the total running time at this point is $\widetilde{O}(k^{2-\eta/2}\mathsf{w}_{\mathsf{max}}^2)$.

NG contains at most $k^{2-\eta}$ edges and therefore the expected number of edges that we put in NG' is $\widetilde{O}(k^{2-3\eta/2})$. For every edge that we discover in NG' we compute the LCS of $\widetilde{O}((2k^{\eta/2}/\lambda^2)^2) = \widetilde{O}(k^{\eta}/\lambda^4)$ pairs of windows. Since computing the LCS of every pair of windows takes time $O(\mathsf{w}_{\mathsf{max}}^2)$ then the expected overall running time is

$$\widetilde{O}\left(k^{2-\eta/2}\mathsf{w}_{\mathsf{max}}^2 + k^{2-3\eta/2}\cdot k^{\eta}/\lambda^4 \cdot \mathsf{w}_{\mathsf{max}}^2\right) = \widetilde{O}\left(k^{2-\eta/2}\mathsf{w}_{\mathsf{max}}^2/\lambda^4\right).$$

Notice that $k^2\mathsf{w}_{\mathsf{max}}^2 \simeq n^2$ and thus the above running time is truly subquadratic.

Sketch of the correctness: We refer the reader to [CDG+18] for a complete proof. The high-level idea is based on the following: Originally, the window size is defined based on a parameter d. Now, suppose we define some larger windows by setting $d' = dk^{\eta/2}$. Let W'_A and W'_B be the two sets of windows we obtain by using d' as the base parameter for constructing windows. Our window-compatibility lemma holds for any window size and therefore there is also a desired window-compatible solution when using W'_A and W'_B.

The intuition behind the proof of [CDG+18] is the following: Suppose we know a window w'_x of W'_A is mapped to a window w'_y of W'_B in the optimal window-compatible solution for W'_A and W'_B. There are at least $k^{\eta/2}$ smaller windows of W_A that lie inside w'_x and similarly w'_y contains at least $k^{\eta/2}$ windows of W_B. Let the two sets be X and Y. There is indeed a window-compatible solution for the windows of X and Y. Now, the question that we need to answer, is how well such a window-compatible solution between w'_x and w'_y is approximated via $\widehat{M}$. If fewer than $\epsilon|X|$ pairs of this mapping are among the edges of NG then we can be sure that the approximation factor does not hurt by much. On the other hand, if more than $\epsilon|X|$ pairs are among the edges of NG then we can imply that one of such edges is discovered via Algorithm 30.12 in NG' and thus M would have the correct value of LCS between all windows of X and all windows of Y. Thus, when we run Algorithm 30.10 on M, the output has an error of at most ϵ even though M does not have the correct estimates for all pairs. □

Chapter 31

Fourier Transform

31.1 One dimensional Fourier transform

The result in this section is based on the unpublished manuscript by Jerry Li, Ruoqi Shen and Zhao Song [LSS19].

Lemma 31.1.1 (Claim 5.2 in [CKPS16])**.** *For any k, there exists $m = O(k^2 \log k)$ such that for any k-Fourier-sparse signal $x(t)$, any $t_0 \geq 0$ and $\tau > 0$, there always exists $C_1, ..., C_m \in \mathbb{C}$ such that $|C_j| \leq 11$ for all $j \in [m]$ and*

$$x(t_0) = \sum_{j \in [m]} C_j \cdot x(t_0 + j \cdot \tau).$$

Lemma 31.1.2 (Bounding absolute by discrete sum on grids)**.** *For any k-Fourier-sparse signal $x(t) = \sum_{j=1}^k v_j e^{2\pi \mathbf{i} f_j t}$, we have*

$$\max_{t \in [0,T]} |x(t)|^2 \leq O(k^6 \log^3 k) \cdot \frac{1}{T} \sum_{t=0}^{T} |x(t)|^2.$$

Proof. Without loss of generality, we fix $T = 1$ and assume $|x(0)|^2 = \max_{t \in [0,T]} |x(t)|^2$. If $t^* = \arg\max_{t \in [0,T]} |x(t)|^2$ is not 0 or $T = 1$, we can rescale the two intervals $[0, t^*]$ and $[t^*, T]$ to $[0, 1]$. By Lemma 31.1.1, we choose $t_0 = 0$ such that $\forall \tau > 0$, there exists $C_1, ..., C_m \in \mathbb{C}$ and

$$x(0) = \sum_{j \in [m]} C_j \cdot x(j \cdot \tau).$$

By the Cauchy-Schwarz inequality, it implies that for any τ,

$$\begin{aligned}|x(0)|^2 &\le m \sum_{j\in[m]} |C_j|^2 |x(j\cdot\tau)|^2 \\ &\lesssim m \sum_{j\in[m]} |x(j\cdot\tau)|^2.\end{aligned}$$

Then,

$$\begin{aligned}|x(0)|^2 &= \frac{1}{\lfloor T/m \rfloor} \sum_{\tau=0}^{\lfloor T/m \rfloor} |x(0)|^2 \\ &\lesssim \frac{m}{T} \sum_{\tau=0}^{\lfloor T/m \rfloor} \left(m \sum_{j\in[m]} |x(j\cdot\tau)|^2 \right) \\ &= \frac{m^2}{T} \sum_{j\in[m]} \sum_{\tau=0}^{\lfloor T/m \rfloor} |x(j\cdot\tau)|^2 \\ &\le \frac{m^3}{T} \sum_{t=0}^{T} |x(t)|^2.\end{aligned}$$

From $m = O(k^2 \log k)$, we obtain $|x(0)|^2 = O(k^6 \log^3 k \|x\|_{[T]})$. □

31.2 High dimensional Fourier transform

The result in this section is based on the unpublished result by Zhao Song [Son17].

Lemma 31.2.1 (d dimensional version of Lemma 5.1 in [CKPS16])**.** *For any d-dimensional k-Fourier-sparse signal $x(t) : \mathbb{R}^d \to \mathbb{C}$ and any duration T, we have*

$$\max_{t\in[0,T]^d} |x(t)|^2 \le k^{O(d)} \|x\|_T^2,$$

where $\|x\|_T^2 = \frac{1}{T^d} \int_{[0,T]^d} |x(t)|^2 \mathrm{d}t$.

Proof. Without loss of generality, we fix $T = 1$. Then $\|x\|_T^2 = \int_{[0,1]^d} |x(t)| \mathrm{d}t$. Because $\|x\|_T^2$ is the average over the interval $[0, T]^d$, if $t^* = \arg\max_{t \in [0,T]^d} |x(t)|^2$ is not 0^d or $T = 1$, we can rescale the two intervals $[0^d, t^*]$ and $[t^*, T^d]$ to $[0, 1]$ and prove the desired property separately. Hence we assume that $|x(0)|^2 = \max_{t \in [0,T]} |x(t)|^2$ in the proof.

The proof of the following Claim can be found in Section 31.3 (is similarly to the proof of Claim 5.2 in [CKPS16])

Claim 31.2.2 (d-variables version of Claim 5.2 in [CKPS16])**.** *For any k and d, there exists $m = O(k^2 \log k)$ such that for any d-dimensional k-Fourier-sparse signal $x(t)$, any $t_0 \in \mathbb{R}^d_{\geq 0}$ and $\tau \in \mathbb{R}^d_{>0}$, there always exist $C_1, C_2, \cdots, C_m \in \mathbb{C}$ such that the following properties hold,*

$$\begin{aligned} &\text{Property I} \quad |C_j| \leq 11 \quad \textit{for all } j \in [m], \\ &\text{Property II} \quad x(t_0) = \sum_{j \in [m]} C_j \cdot x(t_0 + j \cdot \tau). \end{aligned}$$

In the next a few paragraph, we show how to use the above Claim to prove Lemma 31.2.1.

We use 0^d to denote a length-d vector with 0 everywhere. We choose $t_0 = 0^d$ such that $\forall \tau \in \mathbb{R}^d_{>0}$ there always exist $C_1, \cdots, C_m \in \mathbb{C}$, and

$$x(0^d) = \sum_{j \in [m]} C_j \cdot x(j \cdot \tau).$$

By the Cauchy-Schwarz inequality, it implies that for any τ,

$$|x(0^d)|^2 \leq m \sum_{j \in [m]} |C_j|^2 |x(j \cdot \tau)|^2$$

At last, we obtain

$$
\begin{aligned}
|x(0^d)|^2 &= m^d \int_{[0,1/m]^d} |x(0^d)|^2 \mathrm{d}\tau \\
&\lesssim m^d \cdot \int_{[0,1/m]^d} \left(m \sum_{j=1}^{m} |x(j \cdot \tau)|^2 \right) \mathrm{d}\tau \\
&= m^{d+1} \cdot \sum_{j=1}^{m} \int_{[0,1/m]^d} |x(j \cdot \tau)|^2 \mathrm{d}\tau \\
&= m^{d+1} \cdot \sum_{j=1}^{m} \frac{1}{j^d} \int_{[0,j/m]^d} |x(\tau)|^2 \mathrm{d}\tau \\
&= m^{d+1} \cdot \sum_{j=1}^{m} \frac{1}{j^d} \int_{[0,1]^d} |x(\tau)|^2 \mathrm{d}\tau \\
&\lesssim m^{d+1} \log m \cdot \|x\|_T^2 \\
&\leq k^{O(m)} \|x\|_T^2, \qquad (31.1)
\end{aligned}
$$

where the third step follows by moving m outside of the integral and swapping the integration and the summation, the fourth step follows by replacing $j\tau$ by τ, the fifth step follows by $j/m \leq 1$, the sixth step follows by $\sum_{j=1}^{m} 1/j = O(\log m)$ and the definition of $\|x\|_T^2$, and the last step follows by $m = \mathrm{poly}(k)$.

Thus, we have the desired bound. □

31.3 Proof of Claim 31.2.2

For $x(t) = \sum_{i=1}^{k} v_i e^{2\pi \mathbf{i} f_i^\top t}$, where $f_i \in \mathbb{R}^d$ and $t \in \mathbb{R}^d$. We fix $t_0 \in \mathbb{R}^d$ and $\tau \in \mathbb{R}^d$ then rewrite $x(t_0 + j \cdot \tau)$ as a polynomial of $b_i = v_i \cdot e^{2\pi \mathbf{i} f_i^\top t_0}$ and $z_i = e^{2\pi \mathbf{i} f_i^\top \tau}$ for each $i \in [k]$.

$$\begin{aligned} x(t_0 + j \cdot \tau) &= \sum_{i=1}^{k} v_i e^{2\pi \mathbf{i} f_i^\top (t_0 + j\tau)} \\ &= \sum_{i=1}^{k} v_i e^{2\pi \mathbf{i} f_i^\top t_0} e^{2\pi \mathbf{i} f_i^\top j\tau} \\ &= \sum_{i=1}^{k} b_i \cdot z_i^j. \end{aligned}$$

Given k and $z_1, \cdots, z_k$, let $P(z) = \sum_{j=0}^{m} c_j z^j$ be the degree m polynomial in Lemma 5.4 ([CKPS16]).

$$\begin{aligned} \sum_{j=0}^{m} c_j x(t_0 + j\tau) &= \sum_{j=0}^{m} c_j \sum_{i=1}^{k} b_i \cdot z_i^j \\ &= \sum_{i=1}^{k} b_i \sum_{j=0}^{m} c_j \cdot z_i^j \\ &= \sum_{i=1}^{k} b_i P(z_i) \\ &= 0, \end{aligned}$$

where the last step follows by Property I of P(z) in Lemma 5.4 ([CKPS16]). From the Property II and III of $P(z)$ (Lemma 5.4 [CKPS16]), we obtain $x(t_0) = -\sum_{j=1}^{m} c_j x(t_0 + j\tau)$.

Chapter 32

Map-Reduce

Many modern parallel systems, such as MapReduce, Hadoop and Spark, can be modeled well by the MPC model. The MPC model captures well coarse-grained computation on large data — data is distributed to processors, each of which has a sublinear (in the input data) amount of memory and we alternate between rounds of computation and rounds of communication, where each machine can communicate an amount of data as large as the size of its memory. This model is stronger than the classical PRAM model, and it is an intriguing question to design algorithms whose running time is smaller than in the PRAM model.

One fundamental graph problem is connectivity. On an undirected graph with n nodes and m edges, $O(\log n)$ round connectivity algorithms have been known for over 35 years. However, no algorithms with better complexity bounds were known. In this work, we give **fully scalable, faster algorithms for the connectivity problem**, by parameterizing the time complexity as a function of the *diameter* of the graph. Our main result is a $O(\log D \log \log_{m/n} n)$ time connectivity algorithm for diameter-D graphs, using $\Theta(m)$ total memory. If our algorithm can use more memory, it can terminate in fewer rounds, and there is no lower bound on the memory per processor.

We extend our results to related graph problems such as spanning forest, finding a

DFS sequence, exact/approximate minimum spanning forest, and bottleneck spanning forest. We also show that achieving similar bounds for reachability in *directed graphs* would imply faster boolean matrix multiplication algorithms.

We introduce several new algorithmic ideas. We describe a general technique called *double exponential speed problem size reduction* which roughly means that if we can use total memory N to reduce a problem from size n to n/k, for $k = (N/n)^{\Theta(1)}$ in one phase, then we can solve the problem in $O(\log \log_{N/n} n)$ phases. In order to achieve this fast reduction for graph connectivity, we use a multistep algorithm. One key step is a carefully constructed truncated broadcasting scheme where each node broadcasts neighbor sets to its neighbors in a way that limits the size of the resulting neighbor sets. Another key step is *random leader contraction*, where we choose a smaller set of leaders than many previous works do.

This part is based upon the following previous publication

- Alexandr Andoni, Zhao Song, Clifford Stein, Zhengyu Wang, Peilin Zhong
  Parallel graph connectivity in log diameter rounds.
  FOCS 2018 [ASS+18]

32.1 Introduction

Recently, several parallel systems, including MapReduce [DG04, DG08], Hadoop [Whi12], Dryad [IBY+07], Spark [ZCF+10], and others, have become successful in practice. This success has sparked a renewed interest in algorithmic ideas for these parallel systems.

One important theoretical direction has been to develop good models of these modern systems and to relate them to classic models such as PRAM. The work of [FMS+10, KSV10, GSZ11, BKS13, ANOY14] have led to the model of *Massive Parallel Computing* (MPC) that balances accurate modeling with theoretical elegance. MPC is a variant of the Bulk Synchronous Parallel (BSP) model [Val90]. In particular, MPC allows N^δ space per machine (processor), where $\delta \in (0, 1)$ and N is the input size, with alternating rounds of unlimited local computation, and communication of up to N^δ data per processor. An MPC algorithm can equivalently be seen as a small circuit, with arbitrary, N^δ-fan-in gates; the depth of the circuit is the parallel time. Any PRAM algorithm can be simulated on MPC in the same parallel time [KSV10, GSZ11]. However, MPC is in fact more powerful than the PRAM: even computing the XOR of N bits requires near-logarithmic parallel-time on the most powerful CRCW PRAMs [BH89], whereas it takes constant, $O(1/\delta)$, parallel time on the MPC model.

The main algorithmic question of this area is then: for which problems can we design MPC algorithms that are *faster* than the best PRAM algorithms? Indeed, this question has been the focus of several recent papers, see, e.g., [KSV10, LMSV11, EIM11, ANOY14, AG18, AK17, IMS17b, CLM+18]. Graph problems have been particularly well studied and one fundamental problem is *connectivity in a graph*. While this problem has a standard logarithmic time PRAM algorithm [SV82], we do not know whether we can solve it faster in the MPC model.

While we would like *fully scalable* algorithms—which work for any value of $\delta > 0$—there have been graph algorithms that use space close to the number of vertices n of the graph. In particular, the result of [LMSV11] showed a faster algorithm for the setting when the space per machine is polynomially larger than the number of vertices, i.e., $s \geq n^{1+\Omega(1)}$, and hence the number of edges is necessarily $m \geq n^{1+\Omega(1)}$. In fact, similar space restrictions are pervasive for all known sub-logarithmic time graph algorithms, which require $s = \Omega(\frac{n}{\log^{O(1)} n})$ [LMSV11, AG18, AK17, CLM+18] (the only exception is [ANOY14] who consider geometric graphs). We highlight the work of [CLM+18], who manage to obtain *slightly sublinear* space of $n/\log^{\Omega(1)} n$ in $\log^{O(1)} \log n$ parallel time, for the approximate matching problem and [ABB+17] who obtain *slightly sublinear* space of $n/\log^{\Omega(1)} n$ in $O(\log \log n)$ parallel time. We note that the space of $\sim n$ also coincides with the space barrier of the semi-streaming model: essentially no graph problems are solvable in less than n space in the streaming model, unless we have many more passes; see e.g. the survey [McG09].

It remains a major open question whether there exist fully scalable connectivity MPC algorithms with sub-logarithmic time (e.g., for sparse graphs). There are strong indications that such algorithms do *not* exist: [BKS13] show logarithmic lower bounds for restricted algorithms. Alas, showing an unconditional lower bound may be hard to prove, as that would imply circuit lower bounds [RVW16].

In this work, we show **faster, fully scalable algorithms for the connectivity problem**, by parameterizing the time complexity as a function of the *diameter* of the graph. The diameter of the graph is the largest diameter of its connected components. Our main result is an $O(\log D \log \log_{m/n} n)$ time connectivity algorithm for diameter-D graphs with m edges. Parameterizing as a function of D is standard, say, in the distributed computing

literature [PRS16, HHW18]. In fact, some previous MPC algorithms for connectivity in the applied communities have been *conjectured* to obtain $O(\log D)$ time [RMCS13]; alas, we show in Section 32.11 the algorithm of [RMCS13] has a lower bound of $\Omega(\log n)$ time.

Our algorithms exhibit a tradeoff between the total amount of memory available and the number of rounds of computation needed. For example, if the total space is $\Omega(n^{1+\gamma'})$ for some constant $\gamma' > 0$, then our algorithms run in $O(\log D)$ rounds only.

32.1.1 The MPC model

Before stating our full results, we briefly recall the MPC model [BKS13]. A detailed discussion appears in Section 32.7, along with some core primitives implementable in the MPC model.

Definition 32.1.1 ($(\gamma, \delta)-$MPC model)**.** Fix parameters $\gamma, \delta > 0$, and suppose $N \geq 1$ is the input size. There are $p \geq 1$ machines (processors) each with local memory size $s = \Theta(N^{\delta})$, such that $p \cdot s = O(N^{1+\gamma})$. The space size is measured by words, each of $\Theta(\log(s \cdot p))$ bits. The input is distributed on the local memory of $\Theta(N/s)$ input machines. The computation proceeds in rounds. In each round, each machine performs computation on the data in its local memory, and sends messages to other machines at the end of the round. The total size of messages sent or received by a machine in a round is bounded by s. In the next round, each machine only holds the received messages in its local memory. At the end of the computation, the output is distributed on the output machines. Input/output machines and other machines are identical except that input/output machine can hold a part of the input/output. The parallel time of an algorithm is the number of rounds needed to finish the computation.

In this model, the space per machine is sublinear in N, and the total space is only an $O(N^{\gamma})$ factor more than the input size N. In this paper, we consider the case when δ is an arbitrary constant in $(0, 1)$. Our results are for both the most restrictive case of $\gamma = 0$ (total space is linear in the input size), as well as $\gamma > 0$ (for which our algorithms are a bit faster). The model from Definition 32.1.1 matches the model MPC(ϵ) from [BKS13] with $\epsilon = \gamma/(1 + \gamma - \delta)$ and the number of machines $p = O(N^{1+\gamma-\delta})$.

32.1.2 Our Results

While our main result is a $\sim \log D$ time connectivity MPC algorithm, our techniques extend to related graph problems, such as spanning forest, finding a DFS sequence, and exact/approximate minimum spanning forest. We also prove a lower bound showing that, achieving similar bounds for reachability in *directed graphs* would imply faster boolean matrix multiplication algorithms.

We now state our results formally. For all results below, consider an input graph $G = (V, E)$, with $n = |V|$, $N = |V| + |E|$, and D being the upper bound on the diameter of any connected component of G.

Connectivity: In the connectivity problem, the goal is to output the connected components of an input graph G, i.e. at the end of the computation, $\forall v \in V$, there is a unique tuple (x, y) with $x = v$ stored on an output machine, where y is called the color of v. Any two vertices u, v have the same color if and only if they are in the same connected component.

Theorem 32.1.1 (Connectivity in MPC, restatement of Theorem 32.8.4)**.** *For any $\gamma \in [0, 2]$ and any constant $\delta \in (0, 1)$, there is a randomized $(\gamma, \delta) -$ MPC algorithm (see Algorithm 32.3) which outputs the connected components of the graph G in $O(\min(\log D \cdot \log \frac{\log n}{\log(N^{1+\gamma}/n)}, \log n))$ parallel time. The success probability is at least 0.98. In addition, if the algorithm fails, then it returns* FAIL.

Notice that in the most restrictive case of $\gamma = 0$ and $m = n$, we obtain $O(\min(\log D \cdot \log \log n, \log n))$ time. When the total space is slightly larger, or the graph is slightly denser—i.e. $\gamma > c$ or $\log_n m > 1 + c$, where $c > 0$ is an arbitrarily small constant—then we obtain $O(\log D)$ time.

Remark 32.1.1. We note the concurrent and independent work of [ASW18], who also give a connectivity algorithm in the MPC model but with different guarantees. In particular, their runtime is parameterized as a function of λ, which is a lower bound on the spectral gap[1] of the connected components of G. For a graph G with n vertices and $m = \widetilde{O}(n)$ edges, their algorithm runs in $O(\log\log n + \log(1/\lambda))$ parallel time and uses $\widetilde{O}(n/\lambda^2)$ total space. In contrast, our algorithm has a runtime of $O(\log D \cdot \log\log_{N/n} n)$, where D is the largest diameter of a connected component of G, and $N = \Omega(m)$ is the total space available. To compare the two runtimes, we note that: 1) $D \leq O(\frac{\log n}{\lambda})$ for any undirected graph G; and 2) there exist sparse graphs G[2] with n vertices and $O(n)$ edges such that $\frac{1}{\lambda} \geq D \cdot n^{\Omega(1)}$ and $D \leq O(\log n)$. Thus, our results subsume [ASW18] in the case when total space is $N = n^{1+\Omega(1)}$, but are incomparable otherwise.

Spanning forest problem: In the spanning forest problem, the goal is to output a subset of edges of an input graph G such that the output edges together with the vertices of G form a spanning forest of the graph G. In the rooted spanning forest problem, in addition to the edges of the spanning forest, we are also required to orient the edge from child to parent, so that the parent-child pairs form a rooted spanning forest of the input graph G.

Theorem 32.1.2 (Spanning Forest, restatement of Theorem 32.8.14)**.** *For any $\gamma \in [0, 2]$ and any constant $\delta \in (0, 1)$, there is a randomized $(\gamma, \delta) -$ MPC algorithm (see Algorithm 32.11 and Algorithm 32.12) which outputs the rooted spanning forest of the graph G in $O(\min(\log D \cdot \log \frac{\log n}{\log(N^{1+\gamma}/n)}, \log n))$ parallel time. The success probability is at least 0.98. In addition, if*

[1]The spectral gap of a graph G is the second smallest eigenvalue of the normalized Laplacian of G.

[2]We can construct G as the following: a bridge connects two 3-regular expanders where each expander has $n/2$ vertices.

the algorithm fails, then it returns FAIL.

Our spanning forest algorithm can also output an approximation to the diameter, as follows.

Theorem 32.1.3 (Diameter Estimator, restatement of Theorem 32.8.15)**.** *For any $\gamma \in [0,2]$ and any constant $\delta \in (0,1)$, there is a randomized $(\gamma,\delta)-$*MPC *algorithm which outputs a diameter estimator D' of the input graph G in $O(\min(\log D \cdot \log \frac{\log n}{\log(N^{1+\gamma}/n)}, \log n))$ parallel time such that $D \leq D' \leq D^{O(\log(1/\gamma'))}$, where $\gamma' = \frac{\log(N^{1+\gamma}/n)}{\log n}$. The success probability is at least* 0.98*. In addition, if the algorithm fails, then it returns* FAIL*.*

Depth-First-Search sequence: If the input graph G is a tree, then we are able to output a Depth-First-Search sequence of that tree in $O(\log D)+T$ parallel time, where T is parallel time to compute a rooted tree (see Theorem 32.1.2 for our upper bound of T) for G. (See Section 32.7.2 for a discussion how to represent a sequence in the MPC model.)

Theorem 32.1.4 (DFS Sequence of a Tree, restatement of Theorem 32.8.21)**.** *Suppose the graph G is a tree. For any $\gamma \in [\beta,2]$ and any constant $\delta \in (0,1)$, there is a randomized $(\gamma,\delta)-$*MPC *algorithm (Algorithm 32.17) that outputs a Depth-First-Search sequence for the input graph G in $O(\min(\log D \cdot \log(1/\gamma), \log n))$ parallel time, where $\beta = \Theta(\log\log n/\log n)$. The success probability is at least* 0.98*. In addition, if the algorithm fails, then it returns* FAIL*.*

Applications of DFS sequence of a tree include lowest common ancestor, tree distance oracle, the size of every subtree, and others. See Section 32.6.4 for a more detailed discussion of the DFS sequence of a tree.

Minimum Spanning Forest: In the minimum spanning forest problem, the goal is to compute the minimum spanning forest of a weighted graph G.

Theorem 32.1.5 (Minimum Spanning Forest, restatement of Theorem 32.9.3)**.** *Consider a weighted graph G with weights $w : E \to \mathbb{Z}$ such that $\forall e \in E, |w(e)| \leq \text{poly}(n)$. For any $\gamma \in [0, 2]$ and any constant $\delta \in (0, 1)$, there is a randomized $(\gamma, \delta) - \text{MPC}$ algorithm which outputs a minimum spanning forest of G in $O(\min(\log D_{MSF} \cdot \log(\frac{\log n}{1+\gamma \log n}), \log n) \cdot \frac{\log n}{1+\gamma \log n})$ parallel time, where D_{MSF} is the diameter (with respect to the number of edges/hops) of a minimum spanning forest of G. The success probability is at least 0.98. In addition, if the algorithm fails, then it returns* FAIL*.*

We note that we require the bounded weights condition merely to ensure that each weight is described by one word.

Theorem 32.1.6 (Approximate Minimum Spanning Forest, restatement of Theorem 32.9.4)**.** *Consider a weighted graph G with weights $w : E \to \mathbb{Z}_{\geq 0}$ such that $\forall e \in E, |w(e)| \leq \text{poly}(n)$. For any $\epsilon \in (0, 1)$, $\gamma \in [\beta, 2]$ and any constant $\delta \in (0, 1)$, there is a randomized $(\gamma, \delta) - \text{MPC}$ algorithm which can output a $(1 + \epsilon)$ approximate minimum spanning forest for G in $O(\min(\log D_{MSF} \cdot \log(\frac{\log n}{\log(N^{1+\gamma}/(\epsilon^{-1} n \log n))}), \log n))$ parallel time, where $\beta = \Theta(\log(\epsilon^{-1} \log n)/\log n)$, and D_{MSF} is the diameter (with respect to the number of edges/hops) of a minimum spanning forest of G. The success probability is at least 0.98. In addition, if the algorithm fails, then it returns* FAIL*.*

Theorem 32.1.7 (Bottleneck Spanning Forest, restatement of Theorem 32.9.5)**.** *Consider a weighted graph G with weights $w : E \to \mathbb{Z}$ such that $\forall e \in E, |w(e)| \leq \text{poly}(n)$. For any $\gamma \in$*

$[0,2]$ *and any constant* $\delta \in (0,1)$*, there is a randomized* $(\gamma,\delta)-$MPC *algorithm which can output a bottleneck spanning forest for* G *in* $O(\min(\log D_{MSF} \cdot \log(\frac{\log n}{1+\gamma \log n}), \log n) \cdot \log(\frac{\log n}{1+\gamma \log n}))$ *parallel time, where* D_{MSF} *is the diameter (with respect to the number of edges/hops) of a minimum spanning forest of* G*. The success probability is at least* 0.98*. In addition, if the algorithm fails, then it returns* FAIL*.*

Conditional hardness for directed reachability. We also consider the reachability question in the directed graphs, for which we show similar to the above results are unlikely. In particular, we show that if there is a fully scalable multi-query directed reachability $(0,\delta)-$ MPC algorithm with $n^{o(1)}$ parallel time and polynomial local running time, then we can compute the Boolean Matrix Multiplication in $n^{2+\epsilon+o(1)}$ time for arbitrarily small constant $\epsilon > 0$. We note that the equivalent problem for *undirected graphs* can be solved in $O(\log D \log\log n)$ parallel time via Theorem 32.1.1.

Theorem 32.1.8 (Directed Reachability vs. Boolean Matrix Multiplication, restatement of Theorem 32.10.1)**.** *Consider a directed graph* $G = (V,E)$*. If there is a polynomial local running time, fully scalable* $(\gamma,\delta)-$MPC *algorithm that can answer* $|V|+|E|$ *pairs of reachability queries simultaneously for* G *in* $O(|V|^{\alpha})$ *parallel time, then there is a sequential algorithm which can compute the multiplication of two* $n \times n$ *boolean matrices in* $O(n^2 \cdot n^{2\gamma+\alpha+\epsilon})$ *time, where* $\epsilon > 0$ *is a constant which can be arbitrarily small.*

Finally, in Section 32.11 we show hard instances for the algorithm [RMCS13].

32.1.3 Our Techniques

In this section, we give an overview of the various techniques that we use in our algorithms. More details, as well as some of the low level details of the implementation in the MPC model, are defered to later sections.

Before getting into our techniques, we mention two standard tools to help us build our MPC subroutines. The first one is sorting: while in the PRAM model it takes $\sim \log N$ parallel time, sorting takes only constant parallel time in the MPC model [Goo99, GSZ11]. The second tool is indexing/predecessor search [GSZ11], which also has a constant parallel time in MPC. Furthermore, these two tools are fully scalable, and hence all the subroutines built on these two tools are also fully scalable. See Section 32.7 for how to use these two tools to implement the MPC operations needed for our algorithms.

Graph Connectivity: A natural approach to the graph connectivity problem is via the classic primitive of contracting to leaders: select a number of leader verteces, and contract every vertex (or most vertices) to a leader from its connected component (this is usually implemented by labeling the vertex by the corresponding leader). Indeed, many previous works (see e.g. [KSV10, RMCS13, KLM+14b]) are based on this approach. There are two general questions to address in this approach: 1) how to choose leader vertices, and 2) how to label each vertex by its leader. For example, the algorithm in [KSV10] randomly chooses half of the vertices as leaders, and then contracts each non-leader vertex to one of its neighbor leader vertex. Thus, in each round of their algorithm, the number of vertices drops by a constant fraction. At the same time, half of the vertices are leaders, and hence their algorithm still needs at least $\Omega(\log n)$ rounds to contract all the vertices to one leader. Note

that a constant fraction of leaders is needed to ensure that there is a constant fraction of non-leader vertices who are adjacent to at least one leader vertex and hence are contracted. This leader selection method appears optimal for some graphs, e.g. path graphs.

To improve the runtime to $\ll \log n$, one would have to choose a much smaller fraction of the vertices to be leaders. Indeed, for a graph where every vertex has a large degree, say at least $d \gg \log n$, we can choose fewer leaders: namely, we can choose each vertex to be a leader with probability $p = \Theta((\log n)/d)$. Then the number of leaders will be about $\widetilde{O}(n/d)$, while each non-leader vertex has at least one leader neighbor with high probability. After contracting non-leader vertices to leader vertices, the number of remaining vertices is only a $1/d$ fraction of original number of vertices.

By the above discussion, the goal would now be to modify our input graph G so that every vertex has a uniformly large degree, without affecting the connectivity of the graph. An obvious such modification is to add edges between pairs of vertices that are already in the same connected component. In particular, if a vertex v learns of a large number of vertices which are in the same connected component as v, then we can add edges between v and those vertices to increase the degree of v. A naïve way to implement the latter is via broadcasting: each vertex v first initializes a set S_v which contains all the neighbors of v, and then, in each *round*, every vertex v updates the set S_v by adding the union of the sets S_u over all neighbors u of v (old and new). This approach takes log-diameter number of rounds, and each vertex learns all vertices which are in the same connected component at the end of the procedure. However, in a single round, the total communication needed may be as huge as $\Omega(n^3)$ since each of n vertices may have $\Omega(n)$ neighbors, each with a set of size $\Omega(n)$.

Since our goal of each vertex v is to learn only d vertices in the same component (not

necessarily the entire component), we can therefore implement a "truncated" version of the above broadcasting procedure:

1. If S_v already had size d, then we do not need any further operation for S_v.
2. If u is in S_v, and S_u already has d vertices, then we can just put all the elements from S_u into S_v and thus S_v becomes of size d.
3. If $|S_v| < d$, and for every $u \in S_v$, the set S_u is also smaller than d, then we can implement one step of the broadcasting — add the union of S_u's, for all neighbors $u \in S_v$, to S_v.

In the above procedure, if the number of vertices in S_v is smaller than d after the i^{th} round, then we expect S_v to contain all the vertices whose distance to v is at most 2^i. Thus, the above procedure also takes at most log-diameter rounds. Furthermore, the total communication needed is at most $O(n \cdot d^2)$.

Our full graph connectivity algorithm implements the above "truncated broadcasting" procedure iteratively, for values d that follow a certain "schedule", depending on the available space. At the beginning of the algorithm, we have an n vertex graph G with diameter D, and a total of $\Omega(m)$ space. The algorithm proceeds in phases, where each phase takes $O(\log D)$ rounds of communication. In the first phase, the starting number of vertices is $n_1 = n$. We implement a truncated broadcasting procedure where the target degree d is $d_1 = (m/n_1)^{1/2}$, using $O(\log D)$ rounds and $O(m)$ total space. Then we can randomly select $\widetilde{O}(n_1/d_1)$ leaders, and contract all the non-leader vertices to leader vertices. At the end of the first phase, the total number of remaining vertices is at most $n_2 = \widetilde{O}(n_1/d_1) = \widetilde{O}(n_1^{1.5}/m^{0.5})$. In general,

suppose, at the beginning of the i^{th} phase, the number of remaining vertices is n_i. Then we use the truncated broadcasting procedure for value d set to $d_i = (m/n_i)^{1/2}$, thus making each vertex have degree at least $d_i = (m/n_i)^{1/2}$ in $O(\log D)$ number of communication rounds and $O(m)$ total space. Then we choose $\widetilde{O}(n_i/d_i)$ leaders, and, after contracting non-leaders, the number n_{i+1} of remaining vertices is at most $\widetilde{O}(n_i^{1.5}/m^{0.5})$. Let us look at the progress of the value d_i. We have that $d_{i+1} = \widetilde{\Omega}((m/n_{i+1})^{1/2}) = \widetilde{\Omega}((m^{1.5}/n_i^{1.5})^{1/2}) = \widetilde{\Omega}(d_i^{1.5})$. Thus, we are making double exponential progress on d_i, which implies that the total number of phases needed is at most $O(\log \log_{m/n} n)$, and the total parallel time is thus $O(\log D \cdot \log \log_{m/n} n)$.

This technique of double-exponential progress is more general and extends to other problems beyond connectivity. In particular, for a problem, suppose its size is characterized by a parameter n (not necessarily the input size—e.g. in connectivity problem, n is the number of vertices). When n is a constant, the problem can be solved in $O(1)$ parallel time. If there is a procedure that uses total space $\Theta(m)$ to reduce the problem size to at most n/k for $k = (m/n)^c, c = \Omega(1)$, then we can repeat the procedure $O(\log \log_{m/n} n)$ times to solve the overall problem. In particular, after repeating the procedure i times, the problem size is $n_i \leq n_{i-1}/(m/n_{i-1})^c \leq n \cdot (n/m)^{(1+c)^i - 1}$. We call this technique *double-exponential speed problem size reduction*.

Remark 32.1.2. For any problem characterized by a size parameter n, if we can use parallel time T and total space $\Theta(m)$ to reduce the problem size such that the reduced problem size is n/k for $k = (m/n)^{\Omega(1)}$, then we can solve the problem in $O(m)$ total space and $O(T \cdot \log \log_{m/n} n)$ parallel time.

Spanning Forest and Diameter Estimator: Extending a connectivity algorithm to a spanning forest algorithm is usually straightforward. For example, in [KSV10], they only contract a non-leader vertex to an adjacent leader vertex, thus their algorithm can also give a spanning forest, using the contracted edges. Here however, extending our connectivity algorithm to a spanning forest algorithm requires several new ideas. In our connectivity algorithm, because of the added edges, we only ensure that when a vertex u is contracted to a vertex v, u and v must be in the same connected component; but u and v may not be adjacent in the original graph. Thus, we need to record more information to help us build a spanning forest.

We can represent a forest as a collection of parent pointers $\mathrm{part}(v)$, one for each vertex $v \in V$. If v is a root in the forest, then we let $\mathrm{part}(v) = v$. We use $\mathrm{dep}_{\mathrm{par}}(v)$ to denote the depth of v in the forest, i.e. $\mathrm{dep}_{\mathrm{par}}(v)$ is the distance from v to its root. Let $\mathrm{dist}_G(u, v)$ denote the distance between two vertices u and v in a graph G.

Our connectivity algorithm uses the "neighbor increment" procedure described above. We observed that if the set S_v has fewer than d vertices after the i^{th} round, then S_v should contain all the vertices with distance at most 2^i to v. This motivates us to maintain a shortest path tree for S_v, with root v. In the i^{th} round, if we need to update S_v to be $\bigcup_{u \in S_v} S_u$, then we can update the shortest path tree of S_v in the following way:

1. For each $x \in S_u$ for some $u \in S_v$, we can create a tuple (x, u).

2. Then, for each $x \in \left(\bigcup_{u \in S_v} S_u\right) \setminus S_v$, we can sort all the tuples $(x, u_1), (x, u_2), \cdots, (x, u_k)$ such that u_1 minimizes $\min_{u \in S_v} \mathrm{dist}_G(v, u) + \mathrm{dist}_G(u, x)$. Since u is in S_v, x is in S_u, it is easy to get the value of $\mathrm{dist}_G(v, u), \mathrm{dist}_G(u, x)$ by the information of shortest path

tree for S_v and S_u. Then we set the new parent of x in the shortest path tree for S_v to be the parent of x in the shortest path tree for S_{u_1}.

Since S_v before the update contains all the vertices which have distance to v at most 2^{i-1}, the union of the shortest path from x to u_1 and the shortest path from u_1 to v must be the shortest path from x to v. Then by induction, we can show that the parent of x in the shortest path tree for S_{u_1} is also the parent of x in the shortest path tree for updated S_v. Thus, this modified "neighbor increment" procedure can find n local shortest path trees where there is a tree with root v for each vertex v. Furthermore, the procedure still takes $O(\log D)$ rounds. And we can still use $O(nd^2)$ total space to make each shortest path tree have size at least d. Next, we show how to use these n local shortest path trees to construct a forest with the roots in the forest being the leaders.

As discussed in the connectivity algorithm, if every local shortest path tree has size at least d, we can choose each vertex as a leader with probability $p = \Theta((\log n)/d)$ and then every tree will contain at least one leader with high probability. Let L be the set of sampled leaders, and let $\text{dist}_G(v, L)$ be defined as $\min_{u \in L} \text{dist}_G(v, u)$. Let v be a non-leader vertex, i.e. $v \in V \setminus L$. According to the shortest path tree for S_v [3], since $L \cap S_v \neq \emptyset$, we can find a child u of the root v such that $\text{dist}_G(v, L) > \text{dist}_G(u, L)$; in this case we set $\text{part}(v) = u$. For vertex $v \in L$, we can set $\text{part}(v) = v$. We can see now that par denotes a rooted forest where the roots are sampled leaders. Furthermore, since $\forall v \notin L$, $(v, \text{part}(v))$ is from the shortest path tree for S_v, we know that v and $\text{part}(v)$ are adjacent in the original graph G. After doing

[3]The construction of S_v for spanning forest algorithm is slightly different from that described in the connectivity algorithm. S_v in spanning forest algorithm has a stronger property: $\forall u \in V \setminus S_v$, $\text{dist}_G(u, v)$ must be at least $\text{dist}_G(u', v)$ for any $u' \in S_v$.

the above for all nodes v, the forest denoted by the resulting vector par must be a subgraph of the spanning forest of G. We then apply the standard doubling algorithm to contract all the vertices to their leaders (roots), in $O(\log D)$ rounds. Therefore, the problem is reduced to finding a spanning forest in the contracted graph. The number of vertices remaining in the contracted graph is at most $\widetilde{O}(n/d)$, where $d = (m/n)^{\Theta(1)}$. By Remark 32.1.2, we can output a spanning forest in $O(\log D \cdot \log\log_{m/n} n)$ parallel time.

Although the above algorithm can output the edges of a spanning forest, it cannot output a rooted spanning forest. To output a rooted spanning forest, we follow a top-down construction. Suppose now we have a rooted spanning forest of the contracted graph. Since we have all the information of how vertices were contracted, we know the contraction trees in the original graph. To merge these contraction trees into the rooted spanning forest of the contracted graph, we only need to change the root of each contraction tree to a proper vertex in that tree. This changing root operation can be implemented by the doubling algorithm via a divide-and-conquer approach.

Since the spanning forest algorithm needs $O(\log\log_{m/n} n)$ phases to contract all vertices to a single vertex, the total parallel time to compute a rooted spanning forest is $O(\log D \cdot \log\log_{m/n} n)$. Furthermore, the depth of the rooted spanning forest will be at most $O(D^{O(\log\log_{m/n} n)})$. Thus, we can use the doubling algorithm to calculate the depth of the tree, and output this depth as an estimator of the diameter of the input graph.

Depth-First-Search Sequence: Here, when the input graph G is a tree, our goal is to output a DFS sequence for this tree. Once we have this sequence, it is easy to output a rooted tree. Thus, computing a DFS sequence is at least as hard as computing a rooted tree,

and all the previous algorithms need $\Omega(\log n)$ parallel time to do so.

First of all, we use our spanning forest algorithm to compute a rooted tree, reducing the problem to computing a DFS sequence for a rooted tree. The idea is motivated by TeraSort [O'M08]. If the size of the tree is small enough such that it can be handled by a single machine, then we can just use a single machine to generate its DFS sequence. Otherwise, our algorithm can be roughly described as follows. (Recall that δ is the parameter such that each machine has $\Theta(n^{\delta})$ local memory.)

1. Sample $n^{\delta/2}$ leaves $l_1, l_2, \cdots, l_s$.
2. Determine the order of sampled leaves in the DFS sequence.
3. Compute the DFS sequence $\widetilde{A}$ of the tree which only consists of sampled leaves and their ancestors.
4. Compute the DFS sequence A_v of every root-v subtree which does not contain any sampled leaf.
5. Merge $\widetilde{A}$ and all the A_v.

The first and second steps go as follows. Since we only sample $n^{\delta/2}$ leaves, we can send them to a single machine. We generate queries for every pair of sampled leaves where each query (l_i, l_j) queries the lowest common ancestor of (l_i, l_j). We have n^{δ} such queries in total. Since the input tree is rooted, we can use a doubling algorithm to preprocess a data structure in $O(\log D)$ parallel time and answer all the queries simultaneously in $O(\log D)$ parallel time. Thus, we know the lowest common ancestor of any pair of sampled leaves,

and we can store this all on a single machine. Based on the information of lowest common ancestors of each pair of sampled leaves, we are able to determine the order of the leaves.

For the third step, suppose the sampled leaves have order $l_1, l_2, \cdots, l_s$. Let v be the root of the tree. Then the DFS sequence $\widetilde{A}$ should be: the path from v to l_1, the path from l_1 to the lowest common ancestor of (l_1, l_2), the path from the lowest common ancestor of (l_1, l_2) to l_2, the path from l_2 to the lowest common ancestor of (l_2, l_3), ..., the path from l_s to v. We can find these paths simultaneously by a doubling algorithm together with a divide-and-conquer algorithm in $O(\log D)$ parallel time.

In the fourth step, we apply the procedure recursively. Suppose the total number of leaves in the tree is $q \leq n$. Since we randomly sampled $n^{\delta/2}$ number of leaves, with high probability, each subtree which does not contain a sampled leaf will have at most $O(q/n^{\delta/2})$ number of leaves. Thus, the depth of the recursion will be at most a constant, $O(1/\delta)$.

Minimum Spanning Forest and Bottleneck Spanning Forest. Recall that the input is a graph $G = (V, E = (e_1, e_2, \cdots, e_m))$ together with a weight function w on E. Without loss of generality, we only consider the case when all the weights of edges are different, i.e. $w(e_1) < w(e_2) < \cdots < w(e_m)$. Since the weights of edges are different, the minimum spanning forest of the graph is unique. By Kruskal's algorithm, the diameter of the graph induced by the first i edges for any $i \in [m]$ is at most the depth of the minimum spanning forest. Now, let us use D to denote the depth of the minimum spanning forest.

We first discuss the minimum spanning forest algorithm. A crucial observation of Kruskal's algorithm is: if we want to determine which edges in $e_i, e_{i+1}, \cdots, e_j$ are in the minimum spanning forest, we can always contract the first $i-1$ edges to obtain a graph G',

run a minimum spanning forest algorithm on the contracted graph G', and observe whether an edge is included in the spanning forest of G'. Thus, if the total space is $\Theta(m^{1+\gamma})$, we can have m^{γ} copies of the graph, where the i^{th} copy contracts the first $(i-1)\cdot m^{1-\gamma}$ edges. Thus, we are able to divide the edges into m^{γ} groups where each group has $m^{1-\gamma}$ number of edges. We only need to solve the minimum spanning forest problem for each group. Then in the second phase, we can divide the edges into $m^{2\gamma}$ groups where each group has $m^{1-2\gamma}$ number of edges. Thus, the total number of phases needed is at most $O(1/\gamma)$. In each phase, we just need to run our connectivity algorithm to contract the graph.

For the approximate minimum spanning forest algorithm, we use a similar idea. If we want a $(1+\epsilon)$ approximation, then we round each weight to the closest value $(1+\epsilon)^i$ for some integer i. After rounding, there are only $O(1/\epsilon \cdot \log n)$ edge groups. Since our total space is at least $\Omega(m \log(n)/\epsilon)$, we can make $O(1/\epsilon \cdot \log n)$ copies of the graph. The i^{th} copy of the graph contracts all the edges in group $1, 2, \cdots, i-1$. Then, we only need to run our spanning forest algorithm on each copy to determine which edges should be chosen in each group.

Another application of our *double exponential speed problem size reduction* technique is bottleneck spanning forest. For the bottleneck spanning forest, suppose we have $\Theta(km)$ total space. We can have k copies of the graph where the i^{th} copy contracts the first $(i-1)\cdot m/k$ number of edges. We can determine the group of $O(m/k)$ edges which contains the bottleneck edge. Thus, we reduce the problem to $O(m/k)$. According to Remark 32.1.2, the number of phases is at most $O(\log \log_k m)$, and each phase needs T parallel time, where T is the parallel time for spanning forest.

Directed Reachability vs. Boolean Matrix Multiplication If there is a fully scalable multi-query directed reachability MPC algorithm with almost linear total space, we can simulate the algorithm in sequential model. Thus, it will imply a good sequential multi-query directed reachability algorithm which implies a good sequential Boolean Matrix Multiplication algorithm.

32.1.4 Roadmap

The rest of the paper contains the technical details of our algorithms. In Section 32.2, we described a simplified connectivity algorithm. In Section 32.3, we described the notations. In Sections 32.4, 32.5, and 32.6, we give the details of our main algorithms for connectivity, spanning forest and depth first search sequence. In these sections, we focus on the design of the algorithms and the analysis of the number of rounds. In Section 32.7, we describe the MPC model in detail and discuss some known primitives in that model. In Section 32.8, we discuss how to implement the details of our algorithms in the MPC model to achieve the bounds claimed in the previous sections. In Section 32.9, we show how to apply our connectivity and spanning forest algorithm in minimum spanning forest and bottleneck spanning forest problems. In Section 32.11, we show hard instances for the algorithm [RMCS13]. In Section 32.12, we show an alternative approach for random leader selection.

32.2 A Simplified Batch Algorithm for Connectivity

In this section, we show a simplified version of our connectivity algorithm.

Firstly, let us describe the simplified version of truncated broadcasting procedure in the following. Since G' is obtained by adding edges between the vertices in the same component of G. G' will preserve the connectivity of G. The parallel time needed is at most $O(\log D)$ where D is the diameter of G. The procedure takes at most $O(nd^2+m)$ total space.

Truncated Broadcasting for Neighbor Increment:

- **Input**:
  - A graph $G = (V, E)$ with $n = |V|$ vertices and $m = |E|$ number of edges.
  - A parameter d.
- **Output**:
  - A graph $G' = (V, E')$ such that $\forall v \in V$, $|\Gamma(v)| \geq d$. $\triangleright$ $\Gamma(v)$ denotes the neighbors of v.
- **While** $\exists x \in V$ such that $|\Gamma(x)| < d$:
  - For each $v \in V$ with $|\Gamma(v)| < d$:
    - If $\exists u \in \Gamma(v)$ which has $|\Gamma(u)| \geq d$, then $\Gamma(v) \leftarrow \Gamma(v) \cup \Gamma(u)$.
    - Otherwise, $\Gamma(v) \leftarrow \Gamma(v) \cup \bigcup_{u \in \Gamma(v)} \Gamma(u)$.

We can apply the above procedure to make each vertex have a large degree. Next, let us briefly describe how to choose the leaders and implement the contraction operation for the graph where each vertex has a large degree. The following procedure just needs $O(n+m)$ total space and $O(1)$ parallel time. If every vertex has degree at least d, then in the following

procedure we can reduce the number of vertices to $\widetilde{O}(n/d)$ by contracting all the vertices to $\widetilde{O}(n/d)$ number of leaders.

Random Leader Contraction:

- **Input**:
  - A graph $G = (V, E)$ with $n = |V|$ vertices where each vertex has degree at least d.
- **Output**:
  - A graph $G' = (V', E')$ with $\widetilde{O}(n/d)$ vertices.
  - A mapping par : $V \to V'$, such that part(v) is the vertex that v contracts to.
- **Leader Selection:**
  - Let L denote the set of leaders.
  - For each $v \in V$, with probability at least $\widetilde{\Omega}(1/d)$, choose v as a leader, i.e. $L \leftarrow L \cup \{v\}$.
- **Contraction:**
  - For each $v \in L$, let part$(v) = v$, and put v into V'.
  - For each $v \in V \setminus L$, choose $u \in \Gamma(v) \cap L$, and set part$(u) = v$.
  - For each $(u, v) \in E$, if part$(u) \neq$ part(v), put the edge (part(u), part(v)) into E'.

Finally, we describe the simplified version of our connectivity algorithm in the following.

Connectivity:

- **Input**:
  - A graph $G = (V, E)$ with $n = |V|$ vertices and $m = |E|$ edges.
  - Total space N which is $\Theta(m)$.
- **Output**:
  - A mapping $\text{col} : V \to V$ satisfies $\forall u, v \in V, \text{col}(u) = \text{col}(v)$ if and only if u and v are connected.
- **Initialization:**
  - Let $G_0 \leftarrow G, n_0 \leftarrow n$.
- **In phase i:**
  - Compute G'_{i-1} : Increase the degree of every vertex in G_{i-1} to at least $d_i = \Theta\left((N/n_{i-1})^{1/2}\right)$.
  - Compute G_i : Select $n_i = \widetilde{O}(n_{i-1}/d_i)$ leaders in G'_{i-1} and contract all the vertices to the leaders.
  - If v is contracted to u, record $\text{part}(v) = u$.
  - If G_i does not have any edges, then for every vertex v in G_i, set $\text{part}(v) = v$, and exit the loop.
- **Finding the root leader:**
  - For each $v \in V$, find the root of v in par, i.e. find $u = \text{part}(\text{part}(\cdots \text{part}(v)))$ such that $\text{part}(u) = u$.
  - Set $\text{col}(v) = u$.

After phase i, the number of vertices survived is at most $\widetilde{O}(n_{i-1}/(N/n_{i-1})^{1/2})$. By Remark 32.1.2, there will be at most $O(\log \log_{N/n} n)$ phases. For phase i, we need $O(\log D)$ parallel time to increase the neighbors of every vertex in G_{i-1}. The total parallel time is thus

$O(\log D \cdot \log \log_{N/n} n)$. The total space used in phase i is at most $O(m + (N/n_{i-1})^{1/2} \cdot n_{i-1}) = O(N)$.

32.3 Notations

$[n]$ denotes the set $\{1, 2, \cdots, n\}$. Let G be an undirected graph with vertex set V and edge set E. For $v \in V$, $\Gamma_G(v)$ denotes the set of neighbors of v in G, i.e. $\Gamma_G(v) = \{u \in V \mid (v, u) \in E\}$. For any $u, v \in V$, $\mathrm{dist}_G(u, v)$ denotes the distance between u, v in graph G. If u, v are not in the same connected component, then $\mathrm{dist}_G(u, v) = \infty$. If u, v are in the same connected component, then $\mathrm{dist}_G(u, v) < \infty$. For $v \in V$, $\{u \in V \mid \mathrm{dist}_G(u, v) < \infty\}$ is the set of all the vertices in the same connected component as v. The diameter $\mathrm{diam}(G)$ of G is the largest diameter of its components, i.e. $\mathrm{diam}(G) = \max_{u,v \in V : \mathrm{dist}_G(u,v) < \infty} \mathrm{dist}_G(u, v)$.

32.4 Graph Connectivity

32.4.1 Neighbor Increment Operation

In this section, we describe a procedure which can increase the number of neighbors of every vertex and preserve the connectivity at the same time. The input of the procedure is an undirected graph $G = (V, E)$ and a parameter m which is larger than $|V|$. The output is a graph $G' = (V, E')$ such that for each vertex v, either the connected component which contains v is a clique or v has at least $\lceil (m/|V|)^{1/2} \rceil - 1$ neighbors. Furthermore, $|E'| \leq |E| + m$. We use $\Gamma_G(v)$ to denote the neighbors of v in graph G, i.e. $\Gamma_G(v) = \{u \in V \mid (u, v) \in E\}$. Similarly, we let $\Gamma_{G'}(v)$ be the neighbors of v in G', i.e. $\Gamma_{G'}(v) = \{u \in V \mid (u, v) \in E'\}$.

Lemma 32.4.1. *Let $G = (V, E)$ be an undirected graph, $m \in \mathbb{Z}_{\geq 0}$ which has $m \geq 4|V|$. Let $n = |V|$. Let r be the value at the end of the procedure* NeighborIncrement(m, G) *(Algorithm 32.1.) Then $\forall i \in \{0, 1, \cdots, r\}, v \in V$, $S_v^{(i)}$ satisfies the following properties:*

1. $v \in S_v^{(i)}$.
2. $\forall u \in S_v^{(i)}$, $\mathrm{dist}_G(u, v) < \infty$.
3. $|S_v^{(i)}| < \lceil (m/n)^{1/2} \rceil \Rightarrow S_v^{(i)} = \{u \in V \mid \mathrm{dist}_G(u, v) \leq 2^i\}$.
4. $|S_v^{(i)}| \leq m/n$.

Proof. For property 1, we can prove it by induction. When $i = 0$, due to line 3, we know $v \in S_v^{(0)}$. Suppose property 1 holds for $S_v^{(i-1)}$ for all $v \in V$. If $S_v^{(i)}$ is updated by line 17, there are two cases: 1. if $u = v$, then $v \in S_u^{(i-1)}$, and the condition of line 17 does not hold, thus $v \in S_v^{(i)}$; 2. if $u \neq v$, then after implementing line 17, v will not be removed, thus $v \in S_v^{(i)}$.

If $S_v^{(i)}$ is updated by line 20, then since $v \in S_v^{(i-1)}$, v is also in the set $S_v^{(i)}$. Thus, property 1 holds for every $S_v^{(i)}$.

For property 2, we can prove it by induction. When $i = 0$, it is easy to see $S_v^{(0)} \subseteq \Gamma_G(v) \cup \{v\}$, thus property 2 holds for it. Suppose property 2 holds for $S_v^{(i-1)}$ for all $v \in V$. If $S_v^{(i)}$ is updated by line 17, then since $u \in S_v^{(i-1)}$ and $S_v^{(i)} \subseteq S_u^{(i-1)} \cup \{v\}$, all the vertices from $S_v^{(i)}$ are in the same connected component as u and u is in the same connected component as v. Thus, property 2 holds in this case. If $S_v^{(i)}$ is updated by the line 20, then $\forall p \in S_v^{(i)}$, there exists $u \in S_v^{(i-1)}$ such that $p \in S_u^{(i-1)}$. We have p is in the same connected component as u, and u is in the same connected component as v. Thus, property 2 also holds in this case.

For property 3, we can prove it by induction. When $i = 0$, due to line 7, we have $|S_v^{(0)}| < \lceil (m/n)^{1/2} \rceil \rightarrow S_v^{(0)} = \Gamma_G(v) \cup \{v\} = \{u \in V \mid \text{dist}_G(u, v) \leq 1\}$. Suppose property 3 holds for $S_v^{(i-1)}$ for all $v \in V$. Since if $|S_v^{(i)}| < \lceil (m/n)^{1/2} \rceil$, then $S_v^{(i)}$ can only be updated by line 20, and $\forall u \in S_v^{(i-1)}$, it has $|S_u^{(i-1)}| < \lceil (m/n)^{1/2} \rceil$. Thus, $S_v^{(i)} = \bigcup_{u \in S_v^{(i-1)}} S_u^{(i-1)} = \bigcup_{u \in V, \text{dist}_G(u,v) \leq 2^{i-1}} \{p \in V \mid \text{dist}_G(p, u) \leq 2^{i-1}\} = \{u \in V \mid \text{dist}_G(u, v) \leq 2^i\}$. Thus, property 3 holds.

For property 4, we can prove it by induction. When $i = 0$, due to line 7, $\forall v \in V$, we have $|S_v^{(0)}| \leq \lceil (m/n)^{1/2} \rceil \leq m/n$, where the last inequality follows by $m/n \geq 4$. Now suppose property 4 holds for $S_v^{(i-1)}$ for all $v \in V$. If $S_v^{(i)}$ is updated by line 17, then $|S_v^{(i)}| = |S_u^{(i-1)}| \leq m/n$. If $S_v^{(i)}$ is updated by line 20, we know $\forall u \in S_v^{(i-1)}, |S_u^{(i-1)}| < \lceil (m/n)^{1/2} \rceil$. Notice that by property 1, $v \in S_v^{(i-1)}$, so $|S_v^{(i-1)}| < \lceil (m/n)^{1/2} \rceil$. Thus, $|S_v^{(i)}| = |\bigcup_{u \in S_v^{(i-1)}} S_u^{(i-1)}| \leq (m/n)^{1/2} \cdot (m/n)^{1/2} \leq m/n$. □

Algorithm 32.1 Neighbor Increment Operation

      Let $E' = E \cup \bigcup_{v \in V} \{(v, u) \mid v \in S_u^{(r)}$ or $u \in S_v^{(r)}, u \neq v\}$.
      return $G' = (V, E')$
    else
      $r \leftarrow r + 1$.
    end if
  end for
end procedure

The following definition defines the number of iterations of Algorithm 32.1.

Definition 32.4.1. Given an undirected graph $G = (V, E)$ and a parameter $m \in \mathbb{Z}_{\geq 0}, m \geq 4|V|$, the number of iterations of NeighborIncrement(m, G) (Algorithm 32.1) is the value of r at the end of the procedure.

In the following lemma, we characterize the properties of Algorithm 32.1.

Lemma 32.4.2. *Let $G = (V, E)$ be an undirected graph, $m \in \mathbb{Z}_{\geq 0}$ which has $m \geq 4|V|$. Let $G' = (V, E')$ be the output of* NeighborIncrement(m, G). *We have:*

1. *The number of iterations (Definition 32.4.1), $r \leq \min(\lceil \log(\mathrm{diam}(G)) \rceil, \lceil \log(m/n) \rceil) + 1$.*

2. *For all $u, v \in V$, $\mathrm{dist}_G(u, v) < \infty \Leftrightarrow \mathrm{dist}_{G'}(u, v) < \infty$.*

3. *$\forall v \in V$, if $|\Gamma_{G'}(v)| < \lceil (m/n)^{1/2} \rceil - 1$, then the connected component in G' which contains v is a clique. It also implies that $\forall u, v \in V$, if $|\Gamma_{G'}(v)| < \lceil (m/n)^{1/2} \rceil - 1$ and $|\Gamma_{G'}(u)| \geq \lceil (m/n)^{1/2} \rceil - 1$, then $\mathrm{dist}_{G'}(u, v) = \infty$.*

4. *$E \subseteq E', |E'| \leq |E| + m$.*

Proof. For property 1, if $r > \lceil \log(\mathrm{diam}(G)) \rceil + 1$, then let $i = \lceil \log(\mathrm{diam}(G)) \rceil + 1$. Let $v \in V$. By property 3 of Lemma 32.4.1, if $|S_v^{(i)}| < \lceil (m/n)^{1/2} \rceil$, then $S_v^{(i)} = \{u \in V \mid \mathrm{dist}_G(u, v) \leq 2^i\} = \{u \in V \mid \mathrm{dist}_G(u, v) \leq 2 \cdot 2^{\lceil \log(\mathrm{diam}(G)) \rceil}\} = \{u \in V \mid \mathrm{dist}_G(u, v) < \infty\}$. Furthermore, if $|S_v^{(i)}| < \lceil (m/n)^{1/2} \rceil$, then $|S_v^{(i-1)}| < \lceil (m/n)^{1/2} \rceil$, which means that $S_v^{(i-1)} = \{u \in V \mid \mathrm{dist}_G(u, v) \leq 2^{i-1}\} = \{u \in V \mid \mathrm{dist}_G(u, v) \leq 2^{\lceil \log(\mathrm{diam}(G)) \rceil}\} = \{u \in V \mid \mathrm{dist}_G(u, v) <$

$\infty\} = S_v^{(i)}$. Then due to the condition in line 24, it will end the procedure in this round, which contradicts to $r > \lceil \log(\text{diam}(G)) \rceil + 1 = i$. Similarly, if $r > \lceil \log(m/n) \rceil + 1$, then let $i = \lceil \log(m/n) \rceil + 1$. Furthermore, if $|S_v^{(i)}| < \lceil (m/n)^{1/2} \rceil$, then $|S_v^{(i-1)}| < \lceil (m/n)^{1/2} \rceil$, which means that $S_v^{(i-1)} = \{u \in V \mid \text{dist}_G(u, v) \leq 2^{i-1}\} \neq \{u \in V \mid \text{dist}_G(u, v) \leq 2^i\} = S_v^{(i)}$. Thus, there exists $u \in S_v^{(i)}$ such that $|S_v^{(i)}| > \text{dist}_G(u, v) > 2^{i-1} > m/n \geq \lceil (m/n)^{1/2} \rceil$ which leads to a contradiction.

For property 2, if u, v are in the same connected component in G, then since $E \subseteq E'$, u, v are in the same connected component in G'. If u, v are in the same connected component in G', then there should be a path $u = u_1 \to u_2 \to \cdots \to u_p = v$ in G', i.e. $\forall j \in [p-1], (u_j, u_{j+1}) \in E'$. $(u_j, u_{j+1}) \in E'$ implies that either $(u_j, u_{j+1}) \in E$ or $u_j \in S_{u_{j+1}}^{(r)}$ or $u_{j+1} \in S_{u_j}^{(r)}$. By property 2 of Lemma 32.4.1, we know that $\forall j \in [p-1]$, u_j and u_{j+1} are in the same connected component in G. Thus, u and v are in the same connected component in G.

For property 3, due to line 25, if $|\Gamma_{G'}(v)| < \lceil (m/n)^{1/2} \rceil - 1$, then we have $|S_v^{(r)}| < \lceil (m/n)^{1/2} \rceil$. By property 3 of Lemma 32.4.1, and the condition in line 24, we know $\{u \in V \mid \text{dist}_G(u, v) \leq 2^r\} = S_v^{(r)} = S_v^{(r-1)} = \{u \in V \mid \text{dist}_G(u, v) \leq 2^{r-1}\}$. Thus, $S_v^{(r)} = \{u \in V \mid \text{dist}_G(u, v) < \infty\}$. Due to property 2, we have $\Gamma_{G'}(v) \cup \{v\} \subseteq \{u \in V \mid \text{dist}_G(u, v) < \infty\}$. Notice that $S_v^{(r)} \subseteq \Gamma_{G'}(v) \cup \{v\}$, thus, we have $\Gamma_{G'}(v) \cup \{v\} = \{u \in V \mid \text{dist}_G(u, v) < \infty\}$. Let $v' \in \{u \in V \mid \text{dist}_G(u, v) < \infty\}$, then due to property 2, $\Gamma_{G'}(v') \cup \{v'\} \subseteq \{u \in V \mid \text{dist}_G(u, v') < \infty\} = \{u \in V \mid \text{dist}_G(u, v) < \infty\}$, then we have $|\Gamma_{G'}(v') \cup \{v'\}| < \lceil (m/n)^{1/2} \rceil$. Thus, $|S_{v'}^{(r)}| < \lceil (m/n)^{1/2} \rceil$. By property 3 of Lemma 32.4.1, and the condition in line 24, we know $\{u \in V \mid \text{dist}_G(u, v') \leq 2^r\} = S_{v'}^{(r)} = S_{v'}^{(r-1)} = \{u \in V \mid \text{dist}_G(u, v') \leq 2^{r-1}\}$. Thus, $S_{v'}^{(r)} = \{u \in V \mid \text{dist}_G(u, v') < \infty\}$. Thus, $\Gamma_{G'}(v') \cup \{v'\} = \{u \in V \mid \text{dist}_G(u, v') < \infty\} =$

$\{u \in V \mid \text{dist}_G(u, v) < \infty\}$. Thus, $\forall p, q \in \{u \in V \mid \text{dist}_G(u, v) < \infty\}$, we have $(p, q) \in E'$, which means that $\{u \in V \mid \text{dist}_G(u, v) < \infty\}$ is a clique in G'.

Now consider two vertices $u, v \in V$. Suppose $|\Gamma_{G'}(v)| < \lceil (m/n)^{1/2} \rceil - 1$, then we have that $\{p \in V \mid \text{dist}_G(p, v) < \infty\}$ is a clique in G'. Thus, $\forall q \in \{p \in V \mid \text{dist}_G(p, v) < \infty\}$, we have $|\Gamma_{G'}(q)| = |\Gamma_{G'}(v)| < \lceil (m/n)^{1/2} \rceil - 1$. If $|\Gamma_{G'}(u)| \geq \lceil (m/n)^{1/2} \rceil - 1$, then $\text{dist}_{G'}(u, v) = \infty$.

For property 4, by line 25, we have $E \subseteq E'$ and $|E'| \leq |E| + \sum_{v \in V} |S_v^{(r)}| \leq |E| + n \cdot m/n = |E| + m$ where the last inequality follows by the property 4 of Lemma 32.4.1. $\square$

32.4.2 Random Leader Selection

Given an undirected graph $G = (V, E)$, to design a connected component algorithm, a natural way is constantly contracting the vertices in the same component. One way to do the contraction is that we randomly choose some vertices as leaders, then contract non-leader vertices to the neighbor leader vertices.

In this section, we show that if $\forall v \in V$, the number of neighbors of v is large enough, then we can just sample a small number of leaders such that for each non-leader vertex $v \in V$, there is at least one neighbor of v which is chosen as a leader. A more generalized statement is stated in the following lemma.

Lemma 32.4.3. *Let V be a vertex set with n vertices. Let $0 < \gamma \leq n, \delta \in (0, 1)$. For each $v \in V$, let S_v be a subset of $V \setminus \{v\}$ with size at least $\gamma - 1$. Let $l : V \to \{0, 1\}$ be a random hash function such that $\forall v \in V, l(v)$ are i.i.d. Bernoulli random variables, i.e.*

$$l(v) = \begin{cases} 1 & \text{with probability } p; \\ 0 & \text{otherwise.} \end{cases}$$

If $p \geq \min((10 \log(2n/\delta))/\gamma, 1)$, then, with probability at least $1 - \delta$,

1. $\sum_{v \in V} l(v) \leq \frac{3}{2} pn$;
2. $\forall v \in V, \exists u \in S_v \cup \{v\}$ *such that* $l(u) = 1$.

Proof. For a fixed vertex $v \in V$, we have

$$\begin{aligned}
&\Pr\left(\sum_{u\in S_v\cup\{v\}}(\mathbb{E}(l(u))-l(u)) > \frac{1}{2}\sum_{u\in S_v\cup\{v\}}\mathbb{E}(l(u))\right)\\
\leq\ &\exp\left(-\frac{\frac{1}{2}\left(\frac{1}{2}\sum_{u\in S_v\cup\{v\}}\mathbb{E}(l(u))\right)^2}{\sum_{u\in S_v\cup\{v\}}\mathbb{V}(l(u))+\frac{1}{3}\cdot 1\cdot\frac{1}{2}\sum_{u\in S_v\cup\{v\}}\mathbb{E}(l(u))}\right)\\
\leq\ &\exp\left(-\frac{\frac{1}{2}\left(\frac{1}{2}\sum_{u\in S_v\cup\{v\}}\mathbb{E}(l(u))\right)^2}{\sum_{u\in S_v\cup\{v\}}\mathbb{E}(l(u))+\frac{1}{3}\cdot 1\cdot\frac{1}{2}\sum_{u\in S_v\cup\{v\}}\mathbb{E}(l(u))}\right)\\
=\ &\exp\left(-\frac{3}{28}\cdot\sum_{u\in S_v\cup\{v\}}\mathbb{E}(l(u))\right) = \exp\left(-\frac{3}{28}\cdot p\cdot|S_v\cup\{v\}|\right)\leq\frac{\delta}{2n},
\end{aligned}$$

where the first inequality follows by Bernstein inequality and $|l(u) - E(l(u))| \leq 1$, the second inequality follows by $\mathbb{V}(l(u)) \leq \mathbb{E}(l^2(u)) = \mathbb{E}(l(u))$. The last inequality follows by $|S_v \cup \{v\}| \geq \gamma$, and $p \geq \min((10\log(2n/\delta))/\gamma, 1)$. Since $\frac{1}{2}\sum_{u\in S_v\cup\{v\}}\mathbb{E}(l(u)) \geq 1$, with probability at least $1-\delta/(2n)$, $\sum_{u\in S_v\cup\{v\}} l(v) \geq 1$. By taking union bound over all S_v, with probability at least $1-\delta/2$, $\forall v \in V, \exists u \in S_v \cup \{v\}, l(u) = 1$.

Similarly, we have

$$\begin{aligned}
&\Pr\left(\sum_{u\in V}(l(u)-\mathbb{E}(l(u)))>\frac{1}{2}\sum_{u\in V}\mathbb{E}(l(u))\right)\\
\leq\ &\exp\left(-\frac{\frac{1}{2}\left(\frac{1}{2}\sum_{u\in V}\mathbb{E}(l(u))\right)^2}{\sum_{u\in V}\mathbb{V}(l(u))+\frac{1}{3}\cdot 1\cdot\frac{1}{2}\sum_{u\in V}\mathbb{E}(l(u))}\right)\\
\leq\ &\exp\left(-\frac{\frac{1}{2}\left(\frac{1}{2}\sum_{u\in V}\mathbb{E}(l(u))\right)^2}{\sum_{u\in V}\mathbb{E}(l(u))+\frac{1}{3}\cdot 1\cdot\frac{1}{2}\sum_{u\in V}\mathbb{E}(l(u))}\right)\\
=\ &\exp\left(-\frac{3}{28}\cdot\sum_{u\in V}\mathbb{E}(l(u))\right)\\
=\ &\exp\left(-\frac{3}{28}\cdot p\cdot|V|\right)\leq\frac{\delta}{2n}\leq\frac{\delta}{2}.
\end{aligned}$$

Since $\sum_{u\in V}\mathbb{E}(l(u))=p\cdot n$, with probability at least $1-\delta/2$, $\sum_{u\in V}l(u)\leq 1.5pn$.

By taking union bound, with probability at least $1-\delta, \sum_{u\in V}l(u)\leq 1.5pn$ and $\forall v\in V, \exists u\in S_v\cup\{v\}, l(u)=1$. □

If the number of neighbors of each vertex is not large, then we can still have a constant fraction of vertices which can contract to a leader.

Lemma 32.4.4. *Let V be a vertex set with n vertices. Let S_v be a subset of $V\setminus\{v\}$ with size at least 1. Let $l: V\to\{0,1\}$ be a random hash function such that $\forall v\in V, l(v)$ are i.i.d. Bernoulli random variables, i.e.*

$$l(v)=\begin{cases}1 & \text{with probability } \frac{1}{2};\\ 0 & \text{otherwise.}\end{cases}$$

Let $L=\{v\in V\mid l(v)=1\}\cup\{v\in V\mid\forall u\in S_v\cup\{v\}, l(u)=0\}$. $\mathbb{E}(L)\leq 0.75n$.

Proof. For $v\in V$, $\Pr(l(v)=1)=\frac{1}{2}$. Let $u\in S_v$. Then $\Pr(\forall x\in S_v\cup\{v\}, l(x)=0)\leq\Pr(l(v)=0, l(u)=0)=0.25$. $\mathbb{E}(|L|)=\sum_{v\in V}\Pr(v\in L)\leq 0.75n$. □

32.4.3 Tree Contraction Operation

In this section, we introduce the contraction operation. Firstly, let us introduce the concept of the parent pointers which can define a rooted forest.

Definition 32.4.2. Given a set of vertices V, let $\mathrm{par} : V \to V$ satisfy that $\forall v \in V, \exists i > 0$ such that $\mathrm{par}^{(i)}(v) = \mathrm{par}^{(i+1)}(v)$, where $\forall v \in V, j > 0, \mathrm{par}^{(j)}(v)$ is defined as $\mathrm{part}(\mathrm{par}^{(j-1)}(v))$, and $\mathrm{par}^{(0)}(v) = v$. Then, we call such par a set of parent pointers on V. For $v \in V$, if $\mathrm{part}(v) = v$, then we say v is a root of par . par can have more than one root. The depth of $v \in V$, $\mathrm{dep}_{\mathrm{par}}(v)$ is the smallest $i \in \mathbb{Z}_{\geq 0}$ such that $\mathrm{par}^{(i)}(v) = \mathrm{par}^{(i+1)}(v)$. The root of $v \in V$, $\mathrm{par}^{(\infty)}(v)$ is defined as $\mathrm{par}^{(\mathrm{dep}_{\mathrm{par}}(v))}(v)$. The depth of par, $\mathrm{dep}(\mathrm{par})$ is defined as $\max_{v \in V} \mathrm{dep}_{\mathrm{par}}(v)$.

It is easy to see that a set of parent pointers par on V formed a rooted forest on V. For a vertex $v \in V$, if $\mathrm{part}(v) = v$, then v is a root in the forest. Otherwise $\mathrm{part}(v)$ is the parent of v in the forest.

In the following, we define the union operation of several sets of parent pointers.

Definition 32.4.3. Let $\mathrm{par}_1 : V_1 \to V_1, \mathrm{par}_2 : V_2 \to V_2, \cdots, \mathrm{par}_k : V_k \to V_k$ be k sets of parent pointers on vertex sets $V_1, V_2, \cdots, V_k$ respectively, where $\forall i \neq j \in [k], V_i \cap V_j = \emptyset$. Then $\mathrm{par} = \mathrm{par}_1 \cup \mathrm{par}_2 \cup \cdots \cup \mathrm{par}_k$ is a set of parent pointers on the vertex set $V_1 \cup V_2 \cup \cdots \cup V_k$ such that $\forall i \in [k], v \in V_i, \mathrm{part}(v) = \mathrm{par}_i(v)$.

Now we focus on the parent pointers which can preserve the connectivity of the graph.

Definition 32.4.4. Given a graph $G = (V, E)$ and a set of parent pointers par on V, if $\forall v \in V$, we have $\mathrm{dist}_G(v, \mathrm{part}(v)) < \infty$, then par is *compatible* with G.

It is easy to show the following fact:

Fact 32.4.5. *Given a graph $G = (V, E)$ and a set of parent pointers* par *which is compatible with G, then $\forall u, v \in V$ with $\mathrm{par}^{(\infty)}(u) = \mathrm{par}^{(\infty)}(v)$, we have $\mathrm{dist}_G(u, v) < \infty$.*

Proof. By the definition of compatible, $\forall v \in V, \mathrm{dist}_G(v, \mathrm{part}(v)) < \infty$. By induction, $\forall l \in \mathbb{Z}_{>0}, v \in V$, we have $\mathrm{dist}_G(v, \mathrm{par}^{(l)}(v)) \leq \mathrm{dist}_G(v, \mathrm{par}^{(l-1)}(v)) + \mathrm{dist}_G(\mathrm{par}^{(l-1)}(v), \mathrm{par}^{(l)}(v)) < \infty$. Thus, for any pair of vertices $u, v \in V$, if $\mathrm{par}^{(\infty)}(u) = \mathrm{par}^{(\infty)}(v)$, then $\mathrm{dist}_G(u, v) \leq \mathrm{dist}_G(u, \mathrm{par}^{(\infty)}(u)) + \mathrm{dist}_G(\mathrm{par}^{(\infty)}(v), v) < \infty$. □

In this section, we describe a procedure which can be used to reduce the number of vertices. The input of the procedure is an undirected graph $G = (V, E)$ and a set of parent pointers $\mathrm{par} : V \to V$, where par is compatible with G. The output of the procedure will be the root of each vertex in V and an undirected graph $G' = (V', E')$ which satisfies $V' = \{v \in V \mid \mathrm{part}(v) = v\}, E' = \{(u, v) \in V' \times V' \mid u \neq v, \exists (p, q) \in E, \mathrm{par}^{(\infty)}(p) = u, \mathrm{par}^{(\infty)}(q) = v\}$. Notice that V' only contains all the roots in the forest induced by par, and $|E'| \leq |E|$.

Lemma 32.4.6. *Let $G = (V, E)$ be an undirected graph, $\mathrm{par} : V \to V$ be a set of parent pointers (See Definition 32.4.2). Then* TreeContraction(G, par) *(See Algorithm 32.2) will output $(G', g^{(r)})$ with $r \leq \lceil \log \mathrm{dep}(\mathrm{par}) \rceil$ satisfies the following properties:*

1. $\forall v \in V$, $g^{(r)}(v) = \mathrm{par}^{(\infty)}(v)$.
2. $V' = \{v \in V \mid \mathrm{part}(v) = v\}$.
3. $E' = \{(u, v) \in V' \times V' \mid u \neq v, \exists (p, q) \in E, \mathrm{par}^{(\infty)}(p) = u, \mathrm{par}^{(\infty)}(q) = v\}$.

Proof. One crucial observation is the following claim.

Algorithm 32.2 Tree Contraction Operation

1: **procedure** TREECONTRACTION($G = (V, E)$, par : $V \to V$) ▷ Lemma 32.4.6, Corollary 32.4.8
2: ▷ Output: $G' = (V', E')$, $\text{par}^{(\infty)}(v)$ for all $v \in V$
3: Initially, for each $v \in V$ let $g^{(0)}(v) \leftarrow \text{part}(v)$. Let $V' = \emptyset, E' = \emptyset$.
4: $l \leftarrow 0$.
5: **for** $\exists v \in V, \text{part}(g^{(l)}(v)) \neq g^{(l)}(v)$ **do**
6: $l \leftarrow l + 1$.
7: For each $v \in V$, compute $g^{(l)}(v) = g^{(l-1)}(g^{(l-1)}(v))$. ▷ $g^{(l)}$ is $\text{par}^{(2^l)}$
8: **end for**
9: $r \leftarrow l$. ▷ r is the number of iterations, and is used in the analysis.
10: For $v \in V$, if $\text{part}(v) = v$, let $V' \leftarrow V' \cup \{v\}$.
11: For $(u, v) \in E$, if $g^{(r)}(u) \neq g^{(r)}(v)$, let $E' \leftarrow E' \cup \{(g^{(r)}(u), g^{(r)}(v))\}$.
▷ $\forall v \in V$, contract v to $\text{par}^{(\infty)}(v)$
12: **return** $g^{(r)}(v)$ as $\text{par}^{(\infty)}(v)$ for all $v \in V$, and $G' = (V', E')$
13: **end procedure**

Claim 32.4.7. *$\forall l \in \{0, 1, \cdots, r\}, v \in V$, we have $g^{(l)}(v) = \text{par}^{(2^l)}(v)$.*

Proof. The proof is by induction. When $l = 0$, $\forall v \in V, g^{(0)}(v) = \text{part}(v) = \text{par}^{(1)}(v)$, the claim is true. Suppose for $l-1$, we have $\forall v \in V, g^{(l-1)}(v) = \text{par}^{(2^{l-1})}(v)$, then $\forall v \in V, g^{(l)}(v) = g^{(l-1)}(g^{(l-1)}(v)) = \text{par}^{(2^{l-1})}(\text{par}^{(2^{l-1})}(v)) = \text{par}^{(2^l)}(v)$. So the claim is true. □

If $r > \lceil \log \text{dep}(\text{par}) \rceil$, then $r - 1 \geq \lceil \log \text{dep}(\text{par}) \rceil$. Due to claim 32.4.7, we have $\forall v \in V, g^{(r-1)}(v) = \text{par}^{(2^{r-1})}(v) = \text{par}^{(\infty)}(v)$. Due to the condition in line 5, the loop will stop when $l \leq r - 1$ which leads to a contradiction to line 9. Thus, at the end of the algorithm, r should be at most $\lceil \log \text{dep}(\text{par}) \rceil$.

Since we have $\forall v \in V, \text{part}(g^{(r)}(v)) = g^{(r)}(v)$ at the end of the Algorithm 32.2, $\forall v \in V, g^{(r)}(v)$ must be $\text{par}^{(\infty)}(v)$. Then due to line 10 and line 11, we have $V' = \{v \in V \mid \text{part}(v) = v\}, E' = \{(u, v) \in V' \times V' \mid u \neq v, \exists (p, q) \in E, \text{par}^{(\infty)}(p) = u, \text{par}^{(\infty)}(q) = v\}$. □

Definition 32.4.5. Let $G = (V, E)$ be an undirected graph, $\mathrm{par} : V \to V$ be a set of parent pointers (See Definition 32.4.2). Then the number of iteration of TreeContraction(G, par) is defined as the value of r at the end of the procedure.

Corollary 32.4.8 (Preserved connectivity and diameter)**.** *Let $G = (V, E)$ be an undirected graph, $\mathrm{par} : V \to V$ be a set of parent pointers (See Definition 32.4.2) which is compatible (See Definition 32.4.4) with G. Then at the end of the Algorithm 32.2, $r \le \lceil \log \mathrm{dep}(\mathrm{par}) \rceil$ and the output $(G', g^{(r)})$ will satisfy the following properties:*

1. $\mathrm{diam}(G') \le \mathrm{diam}(G)$.
2. $\forall u, v \in V, \mathrm{dist}_G(u, v) < \infty \Rightarrow \mathrm{dist}_{G'}(\mathrm{par}^{(\infty)}(u), \mathrm{par}^{(\infty)}(v)) < \infty$.
3. $\forall u, v \in V, \mathrm{dist}_G(u, v) < \infty \Leftarrow \mathrm{dist}_{G'}(\mathrm{par}^{(\infty)}(u), \mathrm{par}^{(\infty)}(v)) < \infty$.

Proof. By Lemma 32.4.6, we have $r \le \lceil \log \mathrm{dep}(\mathrm{par}) \rceil$, $V' = \{v \in V \mid \mathrm{part}(v) = v\}$ and $E' = \{(u, v) \in V' \times V' \mid u \ne v, \exists (p, q) \in E, \mathrm{par}^{(\infty)}(p) = u, \mathrm{par}^{(\infty)}(q) = v\}$.

For any two vertices $u, v \in V$ which are in the same connected component in G, then there should be a path $u = u_1 \to u_2 \to \cdots \to u_p = v$ in graph G. So $\forall i \in [p-1], (u_i, u_{i+1}) \in E$ which means that either $\mathrm{par}^{(\infty)}(u_i) = \mathrm{par}^{(\infty)}(u_{i+1})$ or $(\mathrm{par}^{(\infty)}(u_i), \mathrm{par}^{(\infty)}(u_{i+1})) \in E'$. Thus, $\mathrm{par}^{(\infty)}(u_1) \to \mathrm{par}^{(\infty)}(u_2) \to \cdots \to \mathrm{par}^{(\infty)}(u_p)$ is a valid path in G', and the length of this path in G' is at most p. Thus, the properties 1 and 2 are true.

For any two vertices $u, v \in V$ which are not in the same connected component in G, but there is a path $\mathrm{par}^{(\infty)}(u) = u'_1 \to u'_2 \to \cdots \to u'_p = \mathrm{par}^{(\infty)}(v)$ in G', then it means that there exists vertices $u_{1,1}, u_{1,2}, u_{2,1}, u_{2,2}, \cdots, u_{p,1}, u_{p,2} \in V$ which satisfies

(a) $\forall i \in [p-1], (u_{i,2}, u_{i+1,1}) \in E, \mathrm{par}^{(\infty)}(u_{i,2}) = u'_i, \mathrm{par}^{(\infty)}(u_{i+1,1}) = u'_{i+1}$.

(b) $u_{1,1} = u, u_{p,2} = v$.

(c) $\forall i \in [p], \mathrm{par}^{(\infty)}(u_{i,1}) = \mathrm{par}^{(\infty)}(u_{i,2})$. By Fact 32.4.5, we have $\mathrm{dist}_G(u_{i,1}, u_{i,2}) < \infty$.

Thus, there exists a path from u to v. This contradicts to that u, v are not in the same connected component. Therefore, property 3 is also true. □

32.4.4 Connectivity Algorithm

In this section, we described a batch algorithm for graph connectivity/connected components problem. The input is an undirected graph $G = (V, E)$, a space/rounds trade-off parameter m, and the rounds parameter $r \leq |V|$. The output is a function $\text{col} : V \to V$ such that $\forall u, v \in V, \text{dist}_G(u, v) < \infty \Leftrightarrow \text{col}(u) = \text{col}(v)$.

The algorithm is described in Algorithm 32.3. The following theorem shows the correctness of Algorithm 32.3.

Theorem 32.4.9 (Correctness of Algorithm 32.3)**.** *Let $G = (V, E)$ be an undirected graph, $m \geq 4|V|$, and $r \leq |V|$ be the rounds parameter. If $\textsc{Connectivity}(G, m, r)$ (Algorithm 32.3) does not output FAIL, then $\forall u, v \in V$, we have $\text{dist}_G(u, v) < \infty \Leftrightarrow \text{col}(u) = \text{col}(v)$.*

Proof. Firstly, we show that the input of line 18 is valid.

Claim 32.4.10. *$\forall i \in [r]$, par_i is a set of parent pointers on V_i'', (See Definition 32.4.2) and is compatible (See Definition 32.4.4) with G_i''.*

Proof. $\forall v \in V_i''$, if $v \in L_i$, then $\text{par}_i(v) = v$. For $v \in V_i'' \setminus L_i$, due to property 3 of Lemma 32.4.2, we have $\text{par}_i(v) \in V_i''$. Since $\text{par}_i(v) \in L_i$, we have $\text{par}_i(\text{par}_i(v)) = \text{par}_i(v)$. Thus, $\text{par}_i : V_i'' \to V_i''$ is a set of parent pointers on V_i''. Due to property 2 of Lemma 32.4.2 and $\text{dist}_{G_i'}(\text{par}_i(v), v) < \infty$, we know that $\text{dist}_{G_{i-1}}(\text{par}_i(v), v) < \infty$. Thus, $\text{dist}_{G_i''}(\text{par}_i(v), v) < \infty$. It implies that par_i is compatible with G_i''. □

The following claim shows that the number of the remaining vertices cannot increase after each round.

Claim 32.4.11. *If* CONNECTIVITY(G, m, r) *does not output FAIL, then* $\forall i \in [r], V_i \subseteq V_i'' \subseteq V_i' = V_{i-1}$.

Proof. Let $i \in [r]$. Due to Claim 32.4.10, the input of line 18 is valid. Then, we can apply property 2 of Lemma 32.4.6 to get $V_i \subseteq V_i''$. By the construction of V_i'' we have $V_i'' \subseteq V_i'$. Since the procedure NEIGHBORINCREMENT(m, G_{i-1}) (Algorithm 32.1) does not change the vertex set, we have $V_i' = V_{i-1}$. □

Now, we show that $\forall u, v \in V_i, \text{dist}_{G_i}(u, v) < \infty \Leftrightarrow \text{dist}_G(u, v) < \infty$.

Claim 32.4.12. *If* CONNECTIVITY(G, m, r) *does not output* FAIL*, then* $\forall i \in [r], \forall u, v \in V_i$, *we have* $\text{dist}_{G_i}(u, v) < \infty \Leftrightarrow \text{dist}_G(u, v) < \infty$.

Proof. The proof is by induction. Suppose $\forall u, v \in V_{i-1}, \text{dist}_{G_{i-1}}(u, v) < \infty \Leftrightarrow \text{dist}_G(u, v) < \infty$. $\forall w, z \in V_i$, according to Claim 32.4.11, $w, z \in V_i''$. By property 2,3 of Lemma 32.4.8, and property 2 of Lemma 32.4.6, $\text{dist}_{G_i}(w, z) < \infty \Leftrightarrow \text{dist}_{G_i''}(w, z) < \infty$. Due to property 2,3 of Lemma 32.4.2, there is no edge in E_{i-1} between V_i'' and $V_i' \setminus V_i''$. According to Claim 32.4.11, $w, z \in V_{i-1}$. Thus, $\text{dist}_{G_i''}(w, z) < \infty \Leftrightarrow \text{dist}_{G_{i-1}}(w, z) < \infty$. By induction hypothesis, we have $\forall w, z \in V_i, \text{dist}_{G_i}(w, z) < \infty \Leftrightarrow \text{dist}_G(w, z)$. □

The following claim states that once a vertex $v \in V$ is contracted to an another vertex, it will never be operated.

Claim 32.4.13. *Suppose* CONNECTIVITY(G, m, r) *does not output* FAIL. $\forall i \in \{0, 1, \cdots, r\}$, $v \in V$, *we have* $h_i(v) = \text{null} \Leftrightarrow v \in V_i$. *Furthermore,* $\forall v \in V, \exists j \in [r]$ *such that* $h_0(v) = h_1(v) = \cdots = h_{j-1}(v) = \text{null}$ *and* $h_j(v) = h_{j+1}(v) = \cdots = h_r(v) \neq \text{null}, \text{dist}_G(v, h_r(v)) < \infty$.

Proof. When $i = 0$, $\forall v \in V$, $h_0(v) = \text{null}, v \in V_0 = V$. Suppose it is true that $\forall v \in V, h_{i-1}(v) = \text{null} \Leftrightarrow v \in V_{i-1}$. If $v \notin V_i$, according to Claim 32.4.11, there are three cases: $v \in V_i'' \setminus V_i, v \in V_i' \setminus V_i'', v \notin V_{i-1}$. In the first case, due to line 22, $h_i(v) \neq \text{null}$. In the second case, due to line 21, $h_i(v) \neq \text{null}$, In the third case, due to line 23, $h_i(v) \neq \text{null}$. If $h_i(v) = \text{null}$, then $h_i(v)$ cannot be updated by line 21, line 22 or line 23 which implies that $v \in V_{i-1}, v \notin V_i' \setminus V_i'', v \notin V_i'' \setminus V_i$. Thus, $v \in V_i$.

Since the procedure does not FAIL, we have $n_r = 0$ which means that $\forall v \in V, h_r(v) \neq \text{null}$. Notice that by line 23, if $h_{i-1}(v) \neq \text{null}$, then $h_i(v) = h_{i-1}(v)$. Thus, $\forall v \in V, \exists j \in [r]$ such that $h_0(v) = h_1(v) = \cdots = h_{j-1}(v) = \text{null}$ and $h_j(v) = h_{j+1}(v) = \cdots = h_r(v) \neq \text{null}$.

For $v \in V$, if $h_j(v) \neq \text{null}$ and $h_{j-1}(v) = \text{null}$, then $h_j(v)$ can only be updated by 21 or line 22. In both cases, $\text{dist}_{G_{j-1}}(v, h_j(v)) < \infty$. By Claim 32.4.12, we have that $\text{dist}_G(v, h_j(v)) < \infty$. □

In the following, we show that h_r is a rooted tree such that $\text{dist}_G(u, v) < \infty \Leftrightarrow u, v$ have the same root. Due to Claim 32.4.13, if $\textsc{Connectivity}(G, m, r)$ does not output FAIL, then $n_r = 0$ which implies that $\forall v \in V, h_r(v) \neq \text{null}$. Thus, we can define $h_r^{(k)}(v)$ for $k \in \mathbb{Z}_{>0}$ as applying h_r on v k times. $\forall v \in V$, by Claim 32.4.13, let $j \in [r]$ satisfy that $h_j(v) \neq \text{null}$ and $h_{j-1}(v) = \text{null}$. If $h_j(v)$ is updated by line 22, then $h_j(h_j(v)) = \text{null}$. If $h_j(v)$ is updated by line 21, then $h_j(h_j(v)) = h_j(v)$. In both cases, h_j cannot create a cycle. Thus, we can define $h_r^{(\infty)}(v) = h_r^{(k)}(v)$ for some k which satisfies $h_r(h_r^{(k)}(v)) = h_r^{(k)}(v)$.

Claim 32.4.14. *Suppose* $\textsc{Connectivity}(G, m, r)$ *does not output* FAIL. *Then* $\forall u, v \in V$, *we have* $\text{dist}_G(u, v) < \infty \Leftrightarrow h_r^{(\infty)}(u) = h_r^{(\infty)}(v)$.

Proof. Let $u, v \in V$. By Claim 32.4.13, if $h_r^{\infty}(u) = h_r^{\infty}(v)$ we have $\text{dist}_G(u, v) < \infty$.

If $\mathrm{dist}_G(u,v) < \infty$, then let $u' = h_r^{(\infty)}(u), v' = h_r^{(\infty)}(v)$. By Claim 32.4.13, $\mathrm{dist}_G(u',v') \leq \mathrm{dist}_G(u,u') + \mathrm{dist}_G(u,v) + \mathrm{dist}_G(v,v') < \infty$, and we can find $j \in [r]$ such that $h_j(u') \neq \text{null}, h_{j-1}(u') = \text{null}$. Without loss of generality, we can assume $h_{j-1}(v') = \text{null}$ (otherwise we can swap u' and v'). Due to Claim 32.4.13, $u', v' \in V_{i-1}$. Since $h_j(u') = h_r(u') = u'$, $h_j(u')$ can be only updated by line 21, and $u' \in V'_j \setminus V''_j$. Then due to property 3 of Lemma 32.4.6, v' should be in $\Gamma_{G'_i}(u) \cup \{u\}$. Since $h_j(v') = h_r(v') = v'$, we can conclude that $u' = v'$. □

If Connectivity(G,m,r) does not output FAIL, then in line 26, col is exactly $h_r^{(\infty)}$. By Claim 32.4.14, we have $\forall u,v \in V, \mathrm{dist}_G(u,v) < \infty \Leftrightarrow \mathrm{col}(u) = \mathrm{col}(v)$.

□

Now let us consider the number of iterations of Algorithm 32.3 and the success probability.

Definition 32.4.6 (Total iterations)**.** Let $G = (V,E)$ be an undirected graph, $\mathrm{poly}(n) \geq m > 4n$, and $r \leq n$ be the rounds parameter where n is the number of vertices in G. The total number of iterations of Connectivity(G,m,r) (Algorithm 32.3) is defined as $\sum_{i=1}^{r}(k_i + r'_i)$, where k_i denotes the number of iterations (See Definition 32.4.1) of NeighborIncrement(m, G_{i-1}) (see line 9), and r'_i denotes the number of iterations (See Definition 32.4.5) of TreeContraction(G''_i, par_i) (see line 18).

Theorem 32.4.15 (Success probability and total iterations)**.** *Let $G = (V,E)$ be an undirected graph, $\mathrm{poly}(n) \geq m > 4n$, and $r \leq n$ be the rounds parameter where $n = |V|$. Let $c > 0$ be a sufficiently large constant. If $r \geq c \log\log_{m/n}(n)$, then with probability at least 0.98,* Connectivity(G,m,r) *(Algorithm 32.3) will not return* FAIL*. If* Connectivity(G,m,r)

succeeds, let k_i denote the number of iterations (See Definition 32.4.1) of NeighborIncrement(m, G_{i-1}) *(see line 9), and let r'_i denote the number of iterations of (See Definition 32.4.5) of* TreeContraction$(G''_i$ *(see line 18), then*

1. $\forall i \in [r]$, $r'_i = 0$.
2. $\forall i \in [r]$, k_i *is at most* $\lceil \log(\mathrm{diam}(G)) \rceil + 1$.
3. *The number of iterations of line 26 is at most* $\lceil \log r \rceil$.
4. $\sum_{i=1}^{r} k_i \leq O(r \log(\mathrm{diam}(G)))$.

Let $c_1 > 0$ be a sufficiently large constant. If $m \geq c_1 n \log^4 n$, then with probability at least 0.99, $\sum_{i=1}^{r} k_i \leq O(\log(\mathrm{diam}(G)) \log \log_{\mathrm{diam}(G)}(n))$. If $m < c_1 n \log^4 n$, then with probability at least 0.98, $\sum_{i=1}^{r} k_i \leq O(\log(\mathrm{diam}(G)) \log \log_{\mathrm{diam}(G)}(n) + (\log \log(n))^2)$.

Proof. Suppose Connectivity(G, m, r) succeeds. Property 1 follows by $\forall v \in V''_i, \mathrm{par}_i(\mathrm{par}_i(v)) = \mathrm{par}_i(v)$ and Lemma 32.4.6. Property 2 follows by $\mathrm{diam}(G_r) \leq \mathrm{diam}(G''_r) \leq \mathrm{diam}(G'_r) \leq \mathrm{diam}(G_{r-1}) \leq \mathrm{diam}(G''_{r-1}) \leq \mathrm{diam}(G'_{r-1}) \leq \cdots \leq \mathrm{diam}(G_0) = \mathrm{diam}(G)$ and property 1 of Lemma 32.4.2. Property 3 follows by the depth of h_r is at most r and Lemma 32.4.6. Property 4 follows by property 2.

Now let us prove the success probability. Let $i \in [r]$. If $p_i < 0.5$, then we can apply Lemma 32.4.3 on vertex set V''_i, parameter γ_i, and hash function l_i. Notice that the set S_v in the statement of Lemma 32.4.3 is $\Gamma_{G'_i}(v)$ in the algorithm. Notice that $|V''_i| \leq n$. Then in the i^{th} round, if $p_i < 0.5$, then with probability at most $1/(100n^2)$, L_i will be $\{v \in V''_i \mid l_i(v) = 1\}$, and $n_i = |L_i| \leq 1.5 p_i n_{i-1}$. By taking union bound over all $i \in [r]$,

we have that with probability at least 0.99, event $\mathcal{E}$ happens: for all $i \in [r]$, if $p_i < 0.5$, then $n_i \le 1.5 p_i n_{i-1} \le 0.75 n_{i-1}$. Suppose $\mathcal{E}$ happens. For $i \in [r], p_i = 0.5$, if we apply Lemma 32.4.4, then condition on n_{i-1}, we have $\mathbb{E}(n_i) \le 0.75 n_{i-1}$. Thus, we know $\forall i \in [r], \mathbb{E}(n_i) \le 0.75\,\mathbb{E}(n_{i-1}) \le 0.75^i n$.

Next, we discuss the case for $p_0 = 0.5$ and the case for $p_0 < 0.5$ separately.

If $p_0 = 0.5$, then $m \le n \cdot (600 \log n)^4$. By Markov's inequality, when $i^* \ge 4 \log_{4/3}(6000 \log n)$, with probability at least 0.99, $n_{i^*} \le n/(600 \log n)^4$ and thus $p_{i^*} < 0.5$. Condition on this event and $\mathcal{E}$, we have

$$
\begin{aligned}
n_r &\le \frac{\left(\frac{\left(\frac{n_{i^*}^{1.5}}{m^{0.5}}(45\log n + 150)\right)^{1.5}}{m^{0.5}}(45\log n + 150)\right)^{\cdots}}{\cdots} && \text{(Apply } r' = r - i^* \text{ times)} \\
&= \frac{n_{i^*}^{1.5^{r'}}}{m^{1.5^{r'}-1}}(45\log n + 150)^{2\cdot(1.5^{r'}-1)} \\
&= n_{i^*}/(m/n_{i^*})^{1.5^{r'}-1} \cdot (45\log n + 150)^{2\cdot(1.5^{r'}-1)} \\
&\le n/\left(m/\left(n_{i^*}(45\log n + 150)^2\right)\right)^{1.5^{r'}-1} \\
&\le n/\left(m/\left(n_{i^*}(45\log n + 150)^2\right)\right)^{1.5^{r'/2}} \\
&\le n/\left(m/n\right)^{1.5^{r'/2}} \le \frac{1}{2},
\end{aligned}
$$

where the second inequality follows by $n_{i^*} \le n$, the third inequality follows by $r' \ge 5$, the forth inequality follows by $n_{i^*} \le n/(600 \log n)^4$, and the last inequality follows by $r' \ge \frac{2}{\log 1.5} \log\log_{m/n}(2n)$. Since $4n \le m \le n \cdot (600 \log n)^4, \log\log_{m/n} n = \Theta(\log\log n)$. Let $c > 0$ be a sufficiently large constant. Thus, when $r \ge c \log\log_{m/n} n \ge i^* + r' = 4\log(6000\log n)/\log(4/3) + \frac{2}{\log 1.5}\log\log_{m/n}(2n)$, with probability at least 0.98, CONNECTIVITY(G, m, r) will not fail.

Since property 1 of Lemma 32.4.2, we have $k_i \leq O(\log(\min(m/n_{i-1}, \mathrm{diam}(G))))$. Thus,

$$\begin{aligned}
&\sum_{i=1}^{r} k_i = \sum_{i=1}^{i^*} k_i + \sum_{i=i^*+1}^{r} k_i \leq O\left((\log\log n)^2\right) + \sum_{i=i^*+1}^{r} k_i \\
&\leq O\left((\log\log n)^2\right) + \sum_{i:i\geq i^*+1, m/n_{i-1}\leq \mathrm{diam}(G)} k_i + \sum_{i:i\leq r, m/n_{i-1}>\mathrm{diam}(G)} k_i \\
&\leq O\left((\log\log n)^2\right) + O\left(\sum_{i=0}^{\lceil \log_{1.25}\log_2(\mathrm{diam}(G))\rceil} \log(2^{1.25^i})\right) + O\left(\sum_{i=0}^{\lceil \log_{1.25}\log_{\mathrm{diam}(G)}(m)\rceil} \log(\mathrm{diam}(G))\right) \\
&\leq O\left((\log\log n)^2\right) + O(\log(\mathrm{diam}(G))) + O(\log(\mathrm{diam}(G))\log\log_{\mathrm{diam}(G)}(n)) \\
&\leq O(\log(\mathrm{diam}(G))\log\log_{\mathrm{diam}(G)}(n) + (\log\log(n))^2),
\end{aligned}$$

where the first inequality follows by $i^* = O(\log\log n)$ and $\forall i \leq [i^*], m/n_{i-1} \leq \mathrm{poly}(\log n)$, the third inequality follows by $m/n_{i+1} \geq (m/n_i)^{1.5}/(45\log n + 150) \geq (m/n_i)^{1.25}$.

If $m > n \cdot (600\log n)^4$, then $\forall i \in \{0\} \cup [r-1]$, we have $p_i < 0.5$. Since $\mathcal{E}$ happens. We have:

$$\begin{aligned}
n_r &\leq \frac{\left(\frac{\left(\frac{n^{1.5}}{m^{0.5}}(45\log n+150)\right)^{1.5}}{m^{0.5}}(45\log n+150)\right)^{\cdots}}{\cdots} \qquad \text{(Apply } r \text{ times)} \\
&= \frac{n^{1.5^r}}{m^{1.5^r-1}}(45\log n+150)^{2\cdot(1.5^r-1)} \\
&= n/(m/n)^{1.5^r-1}\cdot(45\log n+150)^{2\cdot(1.5^r-1)} \\
&= n/\left(m/\left(n(45\log n+150)^2\right)\right)^{1.5^r-1} \\
&\leq n/\left(m/\left(n(45\log n+150)^2\right)\right)^{1.5^{r/2}} \\
&\leq n/\left(m/\left(n(200\log n)^2\right)\right)^{1.5^{r/2}} \\
&\leq \frac{1}{2},
\end{aligned}$$

where the second inequality follows by $r \geq 5$, the third inequality follows by $45 \log n + 150 \leq 200 \log n$, and the last inequality follows by

$$r \geq c \log \log_{m/n} n \geq 2 \log_{1.5} \log_{(m/n)^{1/2}} 2n \geq 2 \log_{1.5} \log_{m/(n(200 \log n)^2)} 2n$$

for a sufficiently large constant $c > 0$.

By property 1 of Lemma 32.4.2, we have $k_i \leq O(\log(\min(m/n_{i-1}, \operatorname{diam}(G))))$. Thus,

$$\begin{aligned}
\sum_{i=1}^{r} k_i &\leq \sum_{m/n_{i-1} \leq \operatorname{diam}(G)} k_i + \sum_{m/n_{i-1} > \operatorname{diam}(G)} k_i \\
&\leq O\left(\sum_{i=0}^{\lceil \log_{1.25} \log_2(\operatorname{diam}(G)) \rceil} \log(2^{1.25^i}) \right) + O\left(\sum_{i=0}^{\lceil \log_{1.25} \log_{\operatorname{diam}(G)}(m) \rceil} \log(\operatorname{diam}(G)) \right) \\
&\leq O(\log(\operatorname{diam}(G))) + O(\log(\operatorname{diam}(G)) \log \log_{\operatorname{diam}(G)}(n)),
\end{aligned}$$

where the first inequality follows by $m/n_{i+1} \geq (m/n_i)^{1.5}/(45 \log n + 150) \geq (m/n_i)^{1.25}$.

Since n_r is an integer, n_r must be 0 when $n_r \leq 1/2$. Let $c > 0$ be a sufficiently large constant. For all $m \geq 4n$, if $r \geq c \log \log_{m/n} n$ then CONNECTIVITY(G, m, r) will succeed with probability at least 0.98.

□

32.5 Spanning Forest

32.5.1 Local Shortest Path Tree

In this section, we introduce an important procedure which will be used in the spanning tree algorithm. Roughly speaking, our procedure can merge several local shortest path trees into a larger local shortest path tree. Before we describe the details of the procedure, let us look at some concepts.

Definition 32.5.1 (Local shortest path tree (LSPT))**.** Let V' be a set of vertices, v be a vertex in V', and $\mathrm{par} : V' \to V'$ be a set of parent pointers (See Definition 32.4.2) on V' which satisfies that v is the only root of par . Let $T = (V', \mathrm{par})$. Given an undirected graph $G = (V, E)$, if $V' \subseteq V$ and $\forall u \in V' \setminus \{v\}, (u, \mathrm{part}(u)) \in E, \mathrm{dep}_{\mathrm{par}}(u) = \mathrm{dist}_G(u, v)$, then we say T is a local shortest path tree (LSPT) in G, and T has root v. The vertex set (V' in the above) in T is denoted as V_T. The set of parent pointers (par in the above) in T is denoted as par_T. For short, $\mathrm{dep}_{\mathrm{par}_T}$ is denoted as dep_T, and $\mathrm{dep}(\mathrm{part}(T))$ is denoted as $\mathrm{dep}(T)$.

Definition 32.5.2. Given an undirected graph $G = (V, E)$, a vertex $v \in V$, and $s \in \mathbb{Z}_{\geq 0}$, we define the ball centered at v with radius s as the set $B_{G,s}(v) = \{u \in V \mid \mathrm{dist}_G(u, v) \leq s\}$.

If in the context graph G is clear, then we use $B_s(v)$ to denote $B_{G,s}(v)$.

Definition 32.5.3 (Local complete shortest path tree (LCSPT))**.** Given an undirected graph $G = (V, E)$, $s \in \mathbb{Z}_{\geq 0}$ and a local shortest path tree $T = (V_T, \mathrm{par}_T)$ in G where T has root $v \in V$. If $V_T = B_{G,s}(v)$, then we call T a local complete shortest path tree (LCSPT) in G. The root of T is v. The radius of T is s.

Let $\widetilde{T} = (V_{\widetilde{T}}, \mathrm{par}_{\widetilde{T}})$ with radius $s_1 \in \mathbb{Z}_{\geq 0}$ and root v be a local complete shortest path tree in some graph $G = (V, E)$. For $s_2 \in \mathbb{Z}_{\geq 0}$, if for every $u \in V_{\widetilde{T}}$, we have a local complete

shortest path tree $T(u) = (V_{T(u)}, \mathrm{par}_{T(u)})$ with root u and radius s_2, then we can compute a larger local complete shortest path tree $\widehat{T}$ with root v and radius $s_1 + s_2$. The procedure is described in Algorithm 32.4.

Lemma 32.5.1. *Let $G = (V, E)$ be an undirected graph, $s_1, s_2 \in \mathbb{Z}_{\geq 0}$, and $v \in V$. Let $\widetilde{T} = (V_{\widetilde{T}}, \mathrm{par}_{\widetilde{T}})$ with root v and radius s_1 be a local complete shortest path tree in G, and $\mathrm{dep}_{\widetilde{T}} : V_{\widetilde{T}} \to \mathbb{Z}_{\geq 0}$ be the depth of every vertex in $\widetilde{T}$. $\forall u \in V_{\widetilde{T}}$, let $T(u)$ with root u and radius s_2 be a local complete shortest path tree in G, and $\mathrm{dep}_{T(u)} : V_{T(u)} \to \mathbb{Z}_{\geq 0}$ be the depth of every vertex in $T(u)$. Let $(\widehat{T} = (V_{\widehat{T}}, \mathrm{par}_{\widehat{T}}), \mathrm{dep}_{\widehat{T}}) = \textsc{TreeExpansion}(\widetilde{T}, \mathrm{dep}_{\widetilde{T}}, \{T(u) \mid u \in V_{\widetilde{T}}\}, \{\mathrm{dep}_{T(u)} \mid u \in V_{\widetilde{T}}\})$ (Algorithm 32.4), then $\widehat{T}$ is a local complete shortest path tree with root v and radius $s_1 + s_2$ in G. In addition, $\mathrm{dep}_{\widehat{T}}$ records the depth of every vertex in $\widehat{T}$.*

Proof. If $x \in B_{s_1+s_2}(v)$, then there must exist $u \in V$ such that $\mathrm{dist}_G(v, u) \leq s_1$ and $\mathrm{dist}_G(u, x) \leq s_2$. Thus, $V_{\widehat{T}} = \bigcup_{u \in \widetilde{T}} V_{T(u)} = \bigcup_{u \in B_{s_1}(v)} B_{s_2}(u) = B_{s_1+s_2}(v)$.

Now we want to prove that $\mathrm{par}_{\widehat{T}} : V_{\widehat{T}} \to V_{\widehat{T}}$ also satisfies the condition that $\widehat{T}$ is a local shortest path tree. We can prove it by induction. If $\mathrm{dist}_G(u, v) = 0$, then it means $u = v$. In this case, $\mathrm{par}_{\widehat{T}}(u) = \mathrm{par}_{\widetilde{T}}(u) = v$, and $h(u) = \mathrm{dep}_{\widetilde{T}}(u) = 0$. Let $s \in [s_1 + s_2]$. Suppose $\forall x \in B_{s-1}(v)$, we have $h(x) = \mathrm{dep}_{\widehat{T}}(x) = \mathrm{dist}_G(x, v)$. If $B_s(v) = B_{s-1}(v)$, then we are already done. Otherwise, let x be the vertex which has $\mathrm{dist}_G(x, v) = s$. If $x \in B_{s_1}(v)$, then $h(x) = \mathrm{dep}_{\widetilde{T}}(x) = \mathrm{dist}_G(x, v)$. Additionally, we have $\mathrm{par}_{\widehat{T}}(x) = \mathrm{par}_{\widetilde{T}}(x)$. Therefore, $\mathrm{dep}_{\widehat{T}}(x) = \mathrm{dep}_{\widehat{T}}(\mathrm{par}_{\widetilde{T}}(x)) + 1 = \mathrm{dist}_G(v, \mathrm{par}_{\widetilde{T}}(x)) + 1 = \mathrm{dist}_G(v, x)$. If $x \in B_{s_2}(v) \setminus B_{s_1}(v)$, then $h(x) = \min_{u:\mathrm{dist}_G(v,u) \leq s_1, \mathrm{dist}_G(u,x) \leq s_2} \mathrm{dep}_{\widetilde{T}}(u) + \mathrm{dep}_{T(u)}(x) = \min_{u:\mathrm{dist}_G(v,u) \leq s_1, \mathrm{dist}_G(u,x) \leq s_2} \mathrm{dist}_G(v, u) + \mathrm{dist}_G(u, x) = \mathrm{dist}_G(v, x) = s$. And we have $\mathrm{dist}_G(v, x) = \mathrm{dist}_G(v, u_x) + \mathrm{dist}_G(u_x, x)$. Notice that $\mathrm{dist}_G(v, \mathrm{par}_{T(u_x)}(x)) = \mathrm{dist}_G(v, u_x) + \mathrm{dist}_G(u_x, \mathrm{par}_{T(u_x)}(x)) = \mathrm{dist}_G(v, x) - 1 = s - 1$.

Thus,

$$\mathrm{dep}_{\widehat{T}}(x) = \mathrm{dep}_{\widehat{T}}(\mathrm{par}_{\widehat{T}}(x)) + 1 = \mathrm{dep}_{\widehat{T}}(\mathrm{par}_{T(u_x)}(x)) + 1 = s.$$

To conclude, $\widehat{T}$ is a local complete shortest path tree with root v and radius $s_1 + s_2$ in G. In addition, $\mathrm{dep}_{\widehat{T}}$ records the depth of every vertex in $\widehat{T}$. $\square$

32.5.2 Multiple Local Shortest Path Trees

In this section, we show a procedure which is a generalization of neighbor increment procedure shown in Section 32.4.1. The input of the procedure is an undirected graph $G = (V, E)$ and a parameter m which is larger than $|V| = n$. The output will be n local shortest path trees (See Definition 32.5.1) such that $\forall v \in V$, there is a shortest path tree with root v. Furthermore, the size of each shortest path tree is at least $\left\lceil (m/|V|)^{1/4} \right\rceil$ and at most $\left\lceil (m/|V|)^{1/2} \right\rceil$. The algorithm is described in Algorithm 32.6. The high level idea is that we firstly use doubling technique and the algorithm described in Section 32.5.1 to get local complete shortest path trees rooted at every vertex with multiple radius, and then use these LCSPTs to find large enough local shortest path trees rooted at every vertex. The doubling algorithm is described in Algorithm 32.5.

Definition 32.5.4. Given a graph $G = (V, E)$ and a parameter $m \in \mathbb{Z}_{\geq 0}, m \geq |V|$, the number of iterations of MultiRadiusLCSPT(G, m) (Algorithm 32.5) is the value of r at the end of the procedure.

Lemma 32.5.2. *Let $G = (V, E)$ be an undirected graph, and m be a parameter which is at least $|V|$. Let $(r, \{T_i(v) \mid i \in \{0\} \cup [r], v \in V\}, \{\text{dep}_{T_i(v)} \mid i \in \{0\} \cup [r], v \in V, T_i(v) \neq \text{null}\}) =$ MultiRadiusLCSPT(G, m) (Algorithm 32.5). We have following properties.*

1. *$\forall i \in \{0\} \cup [r], v \in V$, if $T_i(v) \neq \text{null}$, then $T_i(v)$ is a LCSPT (See Definition 32.5.3) with root v and radius 2^i in G. Furthermore, $\text{dep}_{T_i(v)}$ records the depth of every vertex in $T_i(v)$.*

2. *$\forall i \in \{0\} \cup [r], v \in V$, $|B_{G,2^i}(v)| \geq \lceil (m/n)^{1/4} \rceil \Leftrightarrow T_i(v) = \text{null}$.*

3. *For* $v \in V$, *if* $T_r(v) \neq \text{null}$, *then* $V_{T_r(v)} = \{u \in V \mid \text{dist}_G(u, v) < \infty\}$.

4. *The number of iterations (see Definition 32.5.4)* $r \leq \min(\lceil \log(\text{diam}(G)) \rceil, \lceil \log(m/n) \rceil) + 1$.

Proof. For property 1, we can prove it by induction. If $i = 0$, the property holds by line 4, line 5 and line 7. Now suppose $\forall v \in V$, if $T_{i-1}(v)$ is not null, then $T_{i-1}(v)$ is a LCSPT with root v and radius 2^{i-1} in G, and $\text{dep}_{T_i(v)}$ records the depth of every vertex in $T_i(v)$. For $v \in V$, notice that the only place that will make $T_i(v)$ not null is line 15, and if the procedure run line 15, any of $T_{i-1}(v)$ and $T_{i-1}(u)$ with $u \in V_{T_{i-1}(v)}$ cannot be null. By Lemma 32.5.1, since the radius of $T_{i-1}(v)$ is 2^{i-1}, and $\forall u \in V_{T_{i-1}(v)}, T_{i-1}(u)$ has radius 2^{i-1}, $T_i(v)$ is a LCSPT with root v and radius 2^i. Furthermore $\text{dep}_{T_i(v)}$ records the depth of every vertex in $T_i(v)$.

For property 2, if $i = 0$, then this property holds by line 4 to line 7. For $i \in [r]$, our proof is by induction. Suppose the property holds for $i - 1$. Now consider $T_i(v)$ for $v \in V$. The only way to make $T_i(v)$ not null is line 15. If the procedure invokes line 15, then any of $T_{i-1}(v)$ and $T_{i-1}(u)$ with $u \in V_{T_{i-1}(v)}$ cannot be null. By property 1 and Lemma 32.5.1, $T_i(v)$ will be a LCSPT with root v and radius 2^i in line 15. If $|B_{G,2^i}(v)| \geq \lceil (m/n)^{1/4} \rceil$, then $T_i(v)$ is set to be null in line 16. Thus, we already got $|B_{G,2^i}(v)| \geq \lceil (m/n)^{1/4} \rceil \Rightarrow T_i(v) = \text{null}$. Now we want to show $|B_{G,2^i}(v)| \geq \lceil (m/n)^{1/4} \rceil \Leftarrow T_i(v) = \text{null}$. If $T_i(v) = \text{null}$, then there are three cases. The first case is that $T_i(v)$ is set at line 12. In this case, $T_{i-1}(v) = \text{null}$ implies $|B_{G,2^i}(v)| \geq |B_{G,2^{i-1}}(v)| \geq \lceil (m/n)^{1/4} \rceil$. The second case is that $T_i(v)$ is set at line 13. In this case, $\exists u \in V_{T_{i-1}(v)} = B_{G,2^{i-1}}(v)$ such that $|B_{G,2^{i-1}}(u)| \geq \lceil (m/n)^{1/4} \rceil$ which implies $|B_{G,2^i}(v)| \geq \lceil (m/n)^{1/4} \rceil$. In the final case, $T_i(v)$ is set at line 16, and thus, $|B_{G,2^i}(v)| \geq \lceil (m/n)^{1/4} \rceil$.

For property 3, if $T_r(v) \neq \text{null}$, then by property 1, we know $V_{T_r(v)} = B_{G,2^r}(v)$. By the condition in line 19, we know $V_{T_r(v)} = V_{T_{r-1}(v)}$ which implies $B_{G,2^r}(v) = B_{G,2^{r-1}}(v)$. Thus, $V_{T_r(v)} = \{u \in V \mid \text{dist}_G(u,v) < \infty\}$.

For property 4, we can prove it by contradiction. If $r > \lceil \log(\text{diam}(G)) \rceil + 1$, then let $i = \lceil \log(\text{diam}(G)) \rceil + 1$. By the condition in line 19, we know there is a vertex $v \in V$ such that $T_i(v) \neq \text{null}$ and $V_{T_i(v)} \neq V_{T_{i-1}(v)}$. It means that $B_{G,2^i}(v) \neq B_{G,2^{i-1}}(v)$, i.e. $\exists u \in V, \text{dist}_G(v,u) > 2^{i-1}$. But this contradicts to $i = \lceil \log(\text{diam}(G)) \rceil + 1$. Similarly, if $r > \lceil \log(m/n) \rceil + 1$, then let $i = \lceil \log(m/n) \rceil + 1$. By the condition in line 19, we know there is a vertex $v \in V$ such that $T_i(v) \neq \text{null}$ and $V_{T_i(v)} \neq V_{T_{i-1}(v)}$. If $2^{i-1} \leq \text{diam}(G)$, then we have $V_{T_i(v)} \neq V_{T_{i-1}(v)}$ which leads to a contradiction. If $2^{i-1} \geq \text{diam}(G)$, then $|B_{G,2^{i-1}}(v)| \geq 2^{i-1} \geq m/n \geq \lceil (m/n)^{1/4} \rceil$ which contradicts to property 2. □

Next, we show how to use Algorithm 32.5 to design an algorithm which can output $|V|$ number of local shortest path trees rooted at every vertex in V. The details of the algorithm is described in Algorithm 32.6, and the guarantees of the algorithm is stated in the following lemma.

Lemma 32.5.3. *Let $G = (V, E)$ be an undirected graph, and m be a parameter which is at least $16|V|$. Let $\left(\{\widetilde{T}(v) \mid v \in V\}, \{\text{dep}_{\widetilde{T}(v)} \mid v \in V\}\right) = \text{MultipleLargeTrees}(G, m)$. (Algorithm 32.6) Then, the output satisfies the following properties.*

1. *$\forall v \in V$, $\widetilde{T}(v)$ is a LSPT (See Definition 32.5.1) with root v, and $\text{dep}_{\widetilde{T}(v)}$ records the depth of every vertex in $\widetilde{T}(v)$.*

2. *$\forall v \in V, u \in V_{\widetilde{T}(v)}, w \in V \setminus V_{\widetilde{T}(v)}$, it satisfies $\text{dist}_G(v,u) \leq \text{dist}_G(v,w)$.*

3. $\forall v \in V$, *either* $|V_{\widetilde{T}(v)}| \geq \lceil (m/n)^{1/4} \rceil$ *or* $V_{\widetilde{T}(v)} = \{u \in V \mid \mathrm{dist}_G(u, v) < \infty\}$.

4. $\forall v \in V$, $|V_{\widetilde{T}(v)}| \leq \lfloor (m/n)^{1/2} \rfloor$.

Proof. Before we prove above properties, we first show some crucial observations.

Claim 32.5.4. $\forall v \in V, i \in \{0\} \cup [r]$, *if* $T_i(v) \neq \text{null}$, *then* $T_i(v)$ *is a LCSPT with root* v *and radius* 2^i *in graph* G. *Furthermore,* $\mathrm{dep}_{T_i(v)} : V_{T_i(v)} \to \mathbb{Z}_{\geq 0}$ *records the depth of every vertex in* $T_i(v)$. *If* $T_i(v) = \text{null}$, *then* $|B_{G,2^i}(v)| \geq \lceil (m/n)^{1/4} \rceil$.

Proof. Follows by property 1 and property 2 of Lemma 32.5.2 directly. □

Claim 32.5.5. *Let* $v \in V$ *be a vertex with* $T_r(v) = \text{null}$. *Then,* $\forall i \in \{0\} \cup [r]$, $\widetilde{T}_i(v)$ *is a* LCSPT *(See Definition 32.5.3) with root* v *and radius* $s_i(v)$ *in* G, *and* $\mathrm{dep}_{\widetilde{T}_i(v)}$ *records the depth of every vertex in* $\widetilde{T}_i(v)$. *Furthermore, we have* $|B_{G,s_i(v)}(v)| < \lceil (m/n)^{1/4} \rceil, |B_{G,s_i(v)+2^{r-i}}(v)| \geq \lceil (m/n)^{1/4} \rceil$.

Proof. Let $v \in V$ be a vertex with $T_r(v) = \text{null}$. When $i = 0$, then due to line 5 and line 6, $\widetilde{T}_0(v)$ is a LCSPT (See Definition 32.5.3) with root v and radius $0 = s_0(v)$ in G. According to property 2 of Lemma 32.5.2, since $T_r(v) = \text{null}$, we know $|B_{G,0+2^r}(v)| \geq \lceil (m/n)^{1/4} \rceil$.

For $i \in [r]$, we prove it by induction. Suppose the claim is true for $i - 1$. By Claim 32.5.4, Lemma 32.5.1 and the condition in line 9, if the procedure executes line 10, then we know $\widetilde{T}_i(v)$ is a LCSPT with root v and radius $s_{i-1}(v) + 2^{r-i}$ in G at the end of the execution of line 10, and $\mathrm{dep}_{\widetilde{T}_i(v)}$ records the depth of every vertex in $\widetilde{T}_i(v)$. If $|V_{\widetilde{T}_i(v)}| < \lceil (m/n)^{1/4} \rceil$, then $|B_{G,s_{i-1}(v)+2^{r-i}}(v)| < \lceil (m/n)^{1/4} \rceil$. The procedure will execute line 11, and thus $s_i(v)$ is the radius of $\widetilde{T}_i(v)$. In addition, since $s_i(v) = s_{i-1}(v) + 2^{r-i}$ and

$|B_{G,s_{i-1}(v)+2^{r-i+1}}(v)| \geq \lceil (m/n)^{1/4} \rceil$, we have $|B_{G,s_i(v)+2^{r-i}}(v)| \geq \lceil (m/n)^{1/4} \rceil$. If at the end of line 10, $|V_{\widetilde{T}_i(v)}| \geq \lceil (m/n)^{1/4} \rceil$, then we know $|B_{G,s_{i-1}(v)+2^{r-i}}(v)| \geq \lceil (m/n)^{1/4} \rceil$. In this case, $\widetilde{T}_i(v), s_i(v)$ and $\text{dep}_{\widetilde{T}_i(v)}$ will be set to be $\widetilde{T}_{i-1}(v), s_{i-1}(v)$ and $\text{dep}_{\widetilde{T}_i(v)}$ respectively, and thus $|B_{G,s_i(v)}(v)| < \lceil (m/n)^{1/4} \rceil$. If the condition in line 9 does not hold, then we know $|B_{G,s_{i-1}(v)+2^{r-i}}(v)| \geq \lceil (m/n)^{1/4} \rceil$ by claim 32.5.4. In this case, $\widetilde{T}_i(v), s_i(v)$ and $\text{dep}_{\widetilde{T}_i(v)}$ will also be set to be $\widetilde{T}_{i-1}(v), s_{i-1}(v)$ and $\text{dep}_{\widetilde{T}_i(v)}$ respectively, and thus $|B_{G,s_i(v)}(v)| < \lceil (m/n)^{1/4} \rceil$. □

Claim 32.5.5 shows that for each vertex $v \in V$, we know $\widetilde{T}_r(v)$ is a LCSPT with root v and radius $s_r(v)$ in G such that $|B_{G,s_r(v)}(v)| < \lceil (m/n)^{1/4} \rceil$ and $|B_{G,s_r(v)+1}(v)| \geq \lceil (m/n)^{1/4} \rceil$.

Now, let us prove property 1 and property 2. For $v \in V$, if $T_r(v) \neq \text{null}$, then $\widetilde{T}(v), \text{dep}_{\widetilde{T}(v)}$ will be set to be $T_r(v), \text{dep}_{T_r(v)}$ respectively. By Claim 32.5.4, the properties holds. Let v be a vertex in V with $T_r(v) = \text{null}$. If $\widetilde{T}(v)$ is assigned at line 22, then by Lemma 32.5.1, we know $\widetilde{T}(v)$ is a LCSPT with root v, and $\text{dep}_{\widetilde{T}(v)}$ records the depth of every vertex in $\widetilde{T}(v)$. Thus, both properties hold. If $\widetilde{T}(v)$ is assigned at line 28, then there are two cases for the vertices in $V_{\widetilde{T}(v)}$:

1. If x is in $V_{\widetilde{T}_r(v)}$, then since Claim 32.5.5 shows $\widetilde{T}_r(v)$ is a LCSPT with root v, it is easy to show $\text{dep}_{\widetilde{T}(v)}(x) = \text{dep}_{\widetilde{T}_r(v)}(x) = \text{dist}_G(v, x)$, and $\text{par}_{\widetilde{T}(v)}(x) = \text{par}_{\widetilde{T}_r(v)}(x) \in E$.

2. if x is in $N(u_v)$ but not in $V_{\widetilde{T}_r(v)}$, then since $\widetilde{T}_r(v)$ is a LCSPT with root v and radius $s_r(v)$, $\text{dist}_G(v, x) \geq s_r(v)+1$. Also notice that $\text{dist}_G(v, x) \leq \text{dist}_G(v, u_v)+\text{dist}_G(u_v, x) \leq s_r(v)+1$. Therefore, $\text{dist}_G(v, x) = s_r(v)+1, \text{dep}_{\widetilde{T}(v)}(x) = \text{dep}_{\widetilde{T}(v)}(u_v)+1 = \text{dist}_G(v, x) = s_r(v) + 1$. Since $x \in N(u_v)$, $(\text{par}_{\widetilde{T}(v)}(x), x) = (u_v, x) \in E$.

Thus, $\widetilde{T}$ is a LSPT with root v, and it proves property 1. Due to above both cases, we know $B_{G,s_r(v)}(v) \subseteq V_{\widetilde{T}}$, and $\forall x \in V_{\widetilde{T}(v)}$, $\mathrm{dist}_G(v,x) \leq s_r(v)+1$. Thus, property 2 holds.

For property 3 and property 4, we have two cases. The first case is when v satisfies $T_r(v) \neq \text{null}$. In this case $\widetilde{T}(v) = T_r(v)$, due to property 3, 4 of Lemma 32.5.2, we have $V_{\widetilde{T}(v)} = \{u \in V \mid \mathrm{dist}_G(v,u) < \infty\}$, and $|V_{\widetilde{T}(v)}| < \lceil (m/n)^{1/4} \rceil \leq \lfloor (m/n)^{1/2} \rfloor$. The second case is $T_r(v) = \text{null}$. In this case, if $\widetilde{T}(v)$ is assigned at line 22, then $V_{\widetilde{T}(v)} = B_{G,s_r(v)+1}(v)$. Then by Claim 32.5.5, we can get $|V_{\widetilde{T}(v)}| \geq \lceil (m/n)^{1/4} \rceil$. Because $|V_{\widetilde{T}_r(v)}| < \lceil (m/n)^{1/4} \rceil$ and $\forall u \in V_{\widetilde{T}_r(v)}, |V_{T_0(u)}| < \lceil (m/n)^{1/4} \rceil$, we know $|V_{\widetilde{T}(v)}| \leq \lfloor (m/n)^{1/2} \rfloor$. If $\widetilde{T}(v)$ is assigned at line 28, then $|V_{\widetilde{T}(v)}| \geq |N(u_v)| \geq \lceil (m/n)^{1/4} \rceil$, and $|V_{\widetilde{T}(v)}| \leq |V_{\widetilde{T}_r(v)}| + |N(u_v)| < 2 \cdot \lceil (m/n)^{1/4} \rceil \leq \lfloor (m/n)^{1/2} \rfloor$. □

Definition 32.5.5. Let graph $G = (V, E)$, and let m be a parameter which is at least $16|V|$. The number of iterations of $\left(\{\widetilde{T}(v) \mid v \in V\}, \{\mathrm{dep}_{\widetilde{T}(v)} \mid v \in V\}\right) = \textsc{MultipleLargeTrees}(G, m)$ (Algorithm 32.6) is defined as the value of r in the procedure.

Lemma 32.5.6 (Number of iterations of Algorithm 32.6)**.** *Let $G = (V, E)$ be an undirected graph, and let m be a parameter which is at least $16|V|$. The number of iterations (see Definition 32.5.5) of $\left(\{\widetilde{T}(v) \mid v \in V\}, \{\mathrm{dep}_{\widetilde{T}(v)} \mid v \in V\}\right) = \textsc{MultipleLargeTrees}(G, m)$ (Algorithm 32.6) is at most $\min(\lceil \log(\mathrm{diam}(G)) \rceil, \lceil \log(m/n) \rceil) + 1$.*

Proof. It follows by property 4 of Lemma 32.5.2 directly. □

32.5.3 Path Generation and Root Changing

In this section, we show a procedure which can output a path from a certain vertex to the root in a rooted tree. Then we show how to use the procedure to change the root of a rooted tree to a certain vertex in the tree. To output the vertex-root path, we have two stages. The first stage is using doubling method to compute the depth and the 2^ith (for all $i \in \{0, 1, \cdots, \log(\text{dep})\}$) ancestor of each vertex. The second stage is using divide-and-conquer technique to split the path into segments, and recursively find the path for each segment. Once we have the procedure to find the vertex-root path, then we can use it to implement root-changing. The idea is very simple, if we want to change the root to a certain vertex, we just need to find the path from that vertex to the root, and reverse the parent pointers of every vertex on the path. The path finding procedure is described in Algorithm 32.8. The root changing procedure is described in Algorithm 32.9.

Definition 32.5.6. Let $\text{par} : V \to V$ be a set of parent pointers (See Definition 32.4.2) on a vertex set V. The number of iterations of FindAncestors(par) is defined as the value of r at the end of the procedure.

Lemma 32.5.7. *Let* $\text{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*. Let* $(r, \text{dep}_{\text{par}}, \{g_i \mid i \in \{0\} \cup [r]\}) = \text{FindAncestors}(\text{par})$ *(Algorithm 32.7). Then the number of iterations (see Definition 32.5.6)* r *should be at most* $\lceil \log(\text{dep}(\text{par}) + 1) \rceil$, $\text{dep}_{\text{par}} : V \to \mathbb{Z}_{\geq 0}$ *records the depth of every vertex in* V*, and* $\forall i \in \{0\} \cup [r], v \in V$ $g_i(v) = \text{par}^{(2^i)}(v)$.

Proof. h_l and g_l will satisfies the properties in the following claim.

Claim 32.5.8. $\forall i \in \{0\} \cup [r], v \in V$ $g_i(v) = \text{par}^{(2^i)}(v)$, *and if* $\text{dep}_{\text{par}}(v) \leq 2^i - 1$ *then* $h_i(v) = \text{dep}_{\text{par}}(v)$. *Otherwise* $\text{dep}_{\text{par}}(v) = \text{null}$.

Proof. The proof is by induction. The claim is obviously true when $i = 0$. Suppose the claim is true for $i - 1$. We have $g_i(v) = g_{i-1}(g_{i-1}(v)) = \text{par}^{(2^{i-1})}(\text{par}^{(2^{i-1})}(v)) = \text{par}^{(2^i)}(v)$. If $h_i(v) \neq \text{null}$, then there are two cases. In the first case, we have $h_i(v) = h_{i-1}(v)$. By induction we know $h_i(v) = \text{dep}_{\text{par}}(v)$. In the second case, we have $h_i(v) = h_{i-1}(g_{i-1}(v)) + 2^{i-1} = \text{dep}_{\text{par}}(\text{par}^{(2^{i-1})}(v)) + 2^{i-1}$. Notice that in this case $h_{i-1}(v) = \text{null}$, thus by the induction, $\text{dep}_{\text{par}}(v) \geq 2^{i-1}$. Therefore, $\text{dep}_{\text{par}}(v) = \text{dep}_{\text{par}}(\text{par}^{(2^{i-1})}(v)) + 2^{i-1} = h_i(v)$. If $h_i(v) = \text{null}$, then it means that $h_{i-1}(\text{par}^{(2^{i-1})}(v)) = \text{null}$ which implies that $\text{dep}_{\text{par}}(v) \geq 2^i$. □

Due to the above claim, we know that if $i \geq \lceil \log(\text{dep}_{\text{par}}(v) + 1) \rceil$ then $h_i(v) \neq \text{null}$. Thus, we have $r \leq \lceil \log(\text{dep}(\text{par}) + 1) \rceil$. Since the procedure returns h_r as dep_{par}, the returned dep_{par} is correct. □

Lemma 32.5.9. *Let* $\text{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V. *Let* q *be a vertex in* V. *Let* $(\text{dep}_{\text{par}}, P, w) = \textsc{FindPath}(\text{par}, q)$ *(Algorithm 32.8). Then* $\text{dep}_{\text{par}} : V \to \mathbb{Z}_{\geq 0}$ *records the depth of every vertex in* V *and* $P \subseteq V$ *is the set of all vertices on the path from* q *to the root of* q, *i.e.* $P = \{v \in V \mid \exists k \geq 0, v = \text{par}^{(k)}(q)\}$. *If* $\text{dep}_{\text{par}}(q) \geq 1$, *then* $w = \text{par}^{(\text{dep}_{\text{par}}(q)-1)}(q)$. *Furthermore,* k *should be at most* $\lceil \log(\text{dep}(\text{par})) \rceil$.

Proof. By Lemma 32.5.7, since $(r, \text{dep}_{\text{par}}, \{g_i \mid i \in \{0\} \cup [r]\}) = \textsc{FindAncestors}(\text{par})$, we know r should be at most $\lceil \log(\text{dep}(\text{par}) + 1) \rceil$, $\text{dep}_{\text{par}} : V \to \mathbb{Z}_{\geq 0}$ records the depth of every vertex in V, and $\forall i \in \{0\} \cup [r], v \in V$ $g_i(v) = \text{par}^{(2^i)}(v)$. Thus $k = \lceil \log(\text{dep}_{\text{par}}(q)) \rceil \leq \lceil \log(\text{dep}(\text{par}) + 1) \rceil$

Now let us prove that P is the vertex set of all the vertices on the path from q to the root of q. We use divide-and-conquer to get P. The following claim shows that S_i is a set of segments which is a partition of the path, and each segment has length at most 2^{k-i}.

Claim 32.5.10. *$\forall i \in \{0\} \cup [k]$, S_i satisfies the following properties:*

1. *$\exists (x, y) \in S_i$ such that $x = q$.*
2. *$\exists (x, y) \in S_i$ such that $y = g_r(q)$.*
3. *$\forall (x, y) \in S_i$, $\mathrm{dep}_{\mathrm{par}}(y) - \mathrm{dep}_{\mathrm{par}}(x) \leq 2^{k-i}$.*
4. *$\forall (x, y) \in S_i$, if $y \neq g_r(q)$, then $\exists (x', y') \in S_i, x' = y$.*
5. *$\forall (x, y) \in S_i$, $\exists j \in \mathbb{Z}_{\geq 0}, \mathrm{par}^{(j)}(x) = y$.*

Proof. Our proof is by induction. According to line 4, all the properties hold when $i = 0$. Suppose all the properties hold for $i - 1$. For property 1, by induction we know there exists $(x, y) \in S_{i-1}$ such that $x = q$. Then by line 8 and line 9, there must be an (x, y') in S_i. For property 2, by induction we know there exists $(x, y) \in S_{i-1}$ such that $y = g_r(q)$. Thus, there must be an (x', y) in S_i. For property 3, if (x, y) is added into S_i by line 9, then $\mathrm{dep}_{\mathrm{par}}(x) - \mathrm{dep}_{\mathrm{par}}(y) \leq 2^{k-i}$. Otherwise, in line 8, we have $\mathrm{dep}_{\mathrm{par}}(x) - \mathrm{dep}_{\mathrm{par}}(g_{k-i}(x)) \leq 2^{k-i}, \mathrm{dep}_{\mathrm{par}}(g_{k-i}(x)) - \mathrm{dep}_{\mathrm{par}}(y) \leq 2^{k-i+1} - 2^{k-i} = 2^{k-i}$. For property 4, if (x, y) is added into S_i by line 9, then by induction there is $(y, y') \in S_{i-1}$, and thus by line 9 and line 8, there must be $(y, y'') \in S_i$. Otherwise, in line 8 will generate two pairs $(x, g_{k-i}(x)), (g_{k-i}(x), y)$. For $(x, g_{k-i}(x))$, the property holds. For $(g_{k-i}(x), y)$, there must be $(y, y') \in S_{i-1}$ and thus there should be $(y, y'') \in S_i$. For property 5, since $g_{k-i}(x) = \mathrm{par}^{(k-i)}(x)$, for all pairs generated by line 8 and line 9, the property holds. □

By Claim 32.5.10, we know

$$S_k = \{(q, \text{part}(q)), (\text{part}(q), \text{par}^{(2)}(q)), (\text{par}^{(2)}(q), \text{par}^{(3)}(q)), \cdots, (\text{par}^{(\text{dep}_{\text{par}}(q)-1)}(q), \text{par}^{(\text{dep}_{\text{par}}(q))}(q))\}.$$

Thus, P is the set of all the vertices on the path from q to the root of q. And $w = \text{par}^{(\text{dep}_{\text{par}}(q)-1)}(q)$ when $\text{dep}_{\text{par}}(q) \geq 1$. □

Lemma 32.5.11. *Let* $\text{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*. Let* q *be a vertex in* V*. Let* $\widehat{\text{par}} = \textsc{RootChange}(\text{par}, q)$ *(Algorithm 32.9). Then* $\widehat{\text{par}} : V \to V$ *is still a set of parent pointers (See Definition 32.4.2) on* V*.* $\forall v \in V$*, if* $\text{par}^{(\infty)}(v) = \text{par}^{(\infty)}(q)$ *then* $\widehat{\text{par}}^{(\infty)}(v) = q$*. Otherwise* $\widehat{\text{par}}^{(\infty)}(v) = \text{par}^{(\infty)}(v)$*.* $\forall u \neq v \in V, \text{part}(v) = u \Leftrightarrow$ *either* $\widehat{\text{par}}(v) = u$ *or* $\widehat{\text{par}}(u) = v$*. Furthermore,* $\text{dep}(\widehat{\text{par}}) \leq 2\text{dep}(\text{par})$.

Proof. For a vertex $v \in V$, if $\{u \mid i \in \mathbb{Z}_{\geq 0}, u = \text{par}^{(i)}(v)\} \cap P = \emptyset$, then we have $\forall i \in \mathbb{Z}_{\geq 0}, \text{par}^{(i)}(v) = \widehat{\text{par}}^{(i)}(v)$. According to Lemma 32.5.9, $P = \{u \in V \mid i \in \mathbb{Z}_{\geq 0}, \text{par}^{(i)}(q) = u\}$. Then for all $v \in P \setminus \{q\}$, if $\text{part}(u) = v$ then $\widehat{\text{par}}(v) = u$. Thus, $\forall u \in P$, $\widehat{\text{par}}^{(\infty)}(u) = q$. Let i^* be the smallest number such that $\text{par}^{(i^*)}(v) \in P$. Then $\widehat{\text{par}}^{(i^*)}(v) \in P$. Thus, $\widehat{\text{par}}^{(\infty)}(v) = \widehat{\text{par}}^{(\infty)}(\widehat{\text{par}}^{(i^*)}(v)) = q$. Furthermore, we have $\forall v \in V, \text{dep}(\widehat{\text{par}}) \leq \text{dep}(\text{par}) + \text{dep}_{\text{par}}(q) \leq 2\text{dep}(\text{par})$. □

32.5.4 Spanning Forest Expansion

In this section, we give the definition of spanning forest. If we are given a spanning forest of a contracted graph and spanning trees of each contracted component, then we show a procedure which can merge them to get a spanning forest of the original graph. Before go to the details, let us formally define the spanning forest.

Definition 32.5.7 (Rooted Spanning Forest)**.** Let $G = (V, E)$ be an undirected graph. Let $\mathrm{par} : V \to V$ be a set of parent pointers which is compatible (Definition 32.4.4) with G. If $\forall u, v \in V, \mathrm{dist}_G(u, v) < \infty \Rightarrow \mathrm{par}^{(\infty)}(u) = \mathrm{par}^{(\infty)}(v)$, and $\forall v \in V, \mathrm{part}(v) \neq v \Rightarrow (v, \mathrm{part}(v)) \in E$, then we call par a rooted spanning forest of G.

The Algorithm 32.10 shows how to combine the spanning forest in the contracted graph with local spanning trees to get a spanning forest in the graph before contraction. Figure 32.1 shows an example.

Lemma 32.5.12. *Let $G_2 = (V_2, E_2)$ be an undirected graph. Let $\widetilde{\mathrm{par}} : V_2 \to V_2$ be a set of parent pointers (See Definition 32.4.2) which satisfies that $\forall v \in V_2$ with $\widetilde{\mathrm{par}}(v) \neq v$, $(v, \widetilde{\mathrm{par}}(v))$ must be in E_2. Let $G_1 = (V_1, E_1)$ be an undirected graph satisfies $V_1 = \{v \in V_2 \mid \widetilde{\mathrm{par}}(v) = v\}, E_1 = \{(u, v) \in V_1 \times V_1 \mid u \neq v, \exists (x, y) \in E_2, \widetilde{\mathrm{par}}^{(\infty)}(x) = u, \widetilde{\mathrm{par}}^{(\infty)}(y) = v\}$. Let $\mathrm{par} : V_1 \to V_1$ be a rooted spanning forest (See Definition 32.5.7) of G_1. Let $f : V_1 \times V_1 \to \{\mathrm{null}\} \cup (V_2 \times V_2)$ satisfy the following property: for $u \neq v \in V_1$, if $\mathrm{part}(u) = v$, then $f(u, v) \in \{(x, y) \in E_2 \mid \widetilde{\mathrm{par}}^{(\infty)}(x) = u, \widetilde{\mathrm{par}}^{(\infty)}(y) = v\}$, and $f(v, u) \in \{(x, y) \in E_2 \mid \widetilde{\mathrm{par}}^{(\infty)}(x) = v, \widetilde{\mathrm{par}}^{(\infty)}(y) = u\}$. Let $\widehat{\mathrm{par}} = \textsc{ForestExpansion}(\mathrm{par}, \widetilde{\mathrm{par}}, f)$. Then $\widehat{\mathrm{par}} : V_2 \to V_2$ is a rooted spanning forest of G_2. In addition, $\mathrm{dep}(\widehat{\mathrm{par}}) \leq (2 \cdot \mathrm{dep}(\widetilde{\mathrm{par}}) + 1)(\mathrm{dep}(\mathrm{par}) + 1)$.*

Proof. Let $x, y \in V_2, u = \widetilde{\text{par}}^{(\infty)}(x), v = \widetilde{\text{par}}^{(\infty)}(y) \in V_1$ if $\text{dist}_{G_2}(x, y) < \infty$, then since $E_1 = \{(u', v') \in V_1 \times V_1 \mid u' \neq v', \exists (x', y') \in E_2, \widetilde{\text{par}}^{(\infty)}(x') = u', \widetilde{\text{par}}^{(\infty)}(y') = v'\}$, it must be true that $\text{dist}_{G_1}(u, v) < \infty$. Since par is a spanning forest of G_1, we have $\text{par}^{(\infty)}(u) = \text{par}^{(\infty)}(v)$. It suffices to say $\forall x \in V_2, \widehat{\text{par}}^{(\infty)}(x) = \text{par}^{(\infty)}(\widetilde{\text{par}}^{(\infty)}(x))$. We can prove it by induction on $\text{dep}_{\text{par}}(\widetilde{\text{par}}^{(\infty)}(x))$. Let $u = \widetilde{\text{par}}^{(\infty)}(x)$. If $\text{dep}_{\text{par}}(u) = 0$, then $\text{par}^{(\infty)}(u) = u$. In this case, we have $\widehat{\text{par}}^{(\infty)}(x) = \widetilde{\text{par}}^{(\infty)}(x) = u = \text{par}^{(\infty)}(u) = \text{par}^{(\infty)}(\widetilde{\text{par}}^{(\infty)}(x))$, and also we have $\text{dep}_{\widehat{\text{par}}}(x) = \text{dep}_{\widetilde{\text{par}}}(x)$. Now suppose for all $x \in V_2$ with $\text{dep}_{\text{par}}(\widetilde{\text{par}}^{(\infty)}(x)) \leq i - 1$, it has $\widehat{\text{par}}^{(\infty)}(x) = \text{par}^{(\infty)}(\widetilde{\text{par}}^{(\infty)}(x))$ and $\text{dep}_{\widehat{\text{par}}}(x) \leq i \cdot (2\text{dep}(\widetilde{\text{par}}) + 1)$. Let $y \in V_2$ satisfy $\text{dep}_{\text{par}}(\widetilde{\text{par}}^{(\infty)}(y)) = i$. Let $v = \widetilde{\text{par}}^{(\infty)}(y)$. By line 8 and the properties of f, we know $\widetilde{\text{par}}^{(\infty)}(x_v) = v$, and $\widetilde{\text{par}}^{(\infty)}(y_v) = \text{part}(v)$. By line 9, line 10 and Lemma 32.5.11, we have $\widehat{\text{par}}_v^{(\infty)}(y) = x_v, \widehat{\text{par}}(x_v) = y_v$. Thus, there must be $k \leq 2\text{dep}_{\widehat{\text{par}}}(y)$ such that $\widehat{\text{par}}^{(k)}(y) = x_v$. Since $\widehat{\text{par}}^{(\infty)}(y_v) = \text{par}^{(\infty)}(v)$ and $\text{dep}_{\widehat{\text{par}}}(y_v) \leq i \cdot (2\text{dep}(\widetilde{\text{par}}) + 1)$, we have $\widehat{\text{par}}^{(\infty)}(y) = \text{par}^{(\infty)}(v) = \text{par}^{(\infty)}(\widetilde{\text{par}}^{(\infty)}(y))$ and $\text{dep}_{\widehat{\text{par}}}(y) \leq (i + 1) \cdot (2\text{dep}(\widetilde{\text{par}}) + 1)$.

In addition, by the properties of f and Lemma 32.5.11, $\forall v \in V_2$ with $\widehat{\text{par}}(v) \neq v$, we have $(v, \widehat{\text{par}}(v)) \in E_2$. To conclude, $\widehat{\text{par}} : V_2 \to V_2$ is a spanning forest of G_2, and $\text{dep}(\widehat{\text{par}}) \leq (\text{dep}(\text{par}) + 1)(2\text{dep}(\widetilde{\text{par}}) + 1)$. □

32.5.5 Spanning Forest Algorithm

In this section, we show how to apply the ideas shown in connectivity algorithm to get an spanning forest algorithm. Algorithm 32.11 can output a spanning forest of a graph G, but the edges are not orientated. Then in the Algorithm 32.12, we assign each forest edge an direction thus it is a rooted spanning forest.

Before we prove the correctness of the algorithms, let us briefly introduce the meaning of each variables appeared in the algorithms.

In Algorithm 32.11, G_0 is the original input graph, for $i \in \{0\} \cup [r-1]$, G'_i is obtained by deleting all the small size connected components in G_i, and G_{i+1} is obtained by contracting some vertices of G'_i. For a vertex v in graph G_i, if $h_i(v) = \text{null}$, then it means that the connected component which contains v is deleted when obtaining G'_i. If $h_i(v) \neq \text{null}$, it means that the vertex v is contracted to the vertex $h_i(v)$ when obtaining G_{i+1}. par_i is a rooted forest (may not be spanning) in graph G_i, if a tree from the forest is spanning in G_i, then all the vertex in that tree will be deleted when obtaining G'_i. Otherwise all the vertices in that tree will be contracted to the root, and the root will be one of the vertex in G_{i+1}. Since each connected component in G_{i+1} is obtained by contraction of some vertices in a connected component in G_i, each edge in G_{i+1} must correspond to an edge in G_i where the end vertices of the edge are contracted to different vertices. Thus, each edge in G_i should correspond to an edge in G, and $g_i : E_i \to E$ records the such correspondence. D_i records the edges added to the spanning forest F in the i^{th} round. For each vertex v in graph G_i, $\widetilde{T}_i(v)$ is a local shortest path tree (See definition 32.5.1) which is either with a large size or is a spanning tree in the component of v. L_i is a set of random leaders in G'_i such that in each local shortest path tree $\widetilde{T}_i(v)$, there is at least one leader shown in the tree. The following

lemmas formally state the properties of the algorithm.

Lemma 32.5.13. *Let $G = (V, E)$ be an undirected graph, m be a parameter which is at least $16|V|$, and r be a rounds parameter. If* SpanningForest(G, m, r) *(Algorithm 32.11) does not return FAIL, then* $\mathrm{diam}(G) = \mathrm{diam}(G_0) \geq \mathrm{diam}(G'_0) \geq \mathrm{diam}(G_1) \geq \mathrm{diam}(G'_1) \geq \cdots \geq \mathrm{diam}(G_r)$.

Proof. By property 3 of Lemma 32.5.3, $\forall [i] \in \{0\} \cup [r-1]$, there is no edge between $V_i \setminus V'_i$ and V'_i. Thus, $\mathrm{diam}(G'_i) \leq \mathrm{diam}(G_i)$. Then due to property 1 of Corollary 32.4.8, we have $\mathrm{diam}(G_{i+1}) \leq \mathrm{diam}(G'_i)$. □

Lemma 32.5.14. *Let $G = (V, E)$ be an undirected graph, m be a parameter which is at least $16|V|$, and r be a rounds parameter. If* SpanningForest(G, m, r) *(Algorithm 32.11) does not return FAIL, then* $\forall i \in \{0\} \cup [r-1]$, $\mathrm{dep}(\mathrm{par}_i) \leq \min(\mathrm{diam}(G), \lfloor (m/n_i)^{1/2} \rfloor)$.

Proof. Let $v \in V_i$. If $v \in V_i \setminus V'_i$, then due to property 3 of Lemma 32.5.3, we have $V_{\widetilde{T}_i(v)} = V_{\widetilde{T}_i(u_v)}$. Due to Lemma 32.5.13 and Lemma 32.5.3, we have $\mathrm{dep}_{\mathrm{par}_i}(v) \leq \mathrm{dep}(\widetilde{T}_i(u_v)) \leq \min(\mathrm{diam}(G), \lfloor (m/n_i)^{1/2} \rfloor)$. For $v \in V_i$, we define $\mathrm{dist}_{G_i}(v, L_i) = \min_{u \in L_i} \mathrm{dist}_{G_i}(v, u)$. By Lemma 32.5.3, we know $\mathrm{dist}_{G_i}(v, L_i) = \mathrm{dist}_{G_i}(v, z_i(v))$. Since $\widetilde{T}_i(v)$ is a LSPT (See Definition 32.5.1), by applying Lemma 32.5.9, we know $\mathrm{dist}_{G_i}(v, L_i) = \mathrm{dist}_{G_i}(w_i(v), L_i) + 1$, and $(v, w_i(v)) \in E_i$. Thus, by induction on $\mathrm{dist}_{G_i}(v, L_i)$, we can get $\mathrm{dep}_{\mathrm{par}_i}(v) \leq \mathrm{dist}_{G_i}(v, L_i)$. By Lemma 32.5.13 and Lemma 32.5.3, we can conclude $\mathrm{dep}(\mathrm{par}_i)(v) \leq \min(\mathrm{diam}(G), \lfloor (m/n_i)^{1/2} \rfloor)$. □

Lemma 32.5.15. *Let $G = (V, E)$ be an undirected graph, m be a parameter which is at least $16|V|$, and r be a rounds parameter. If* SpanningForest(G, m, r) *(Algorithm 32.11) does*

not return FAIL, then $\forall i \in \{-1, 0\} \cup [r-1]$, *we can define*

$$\forall v \in V, h^{(i)}(v) = \begin{cases} v & i = -1; \\ h_i(h^{(i-1)}(v)) & h^{(i-1)}(v) \neq \text{null}; \\ \text{null} & \text{otherwise .} \end{cases}$$

Then we have following properties:

1. *If* $h^{(i)}(v) \neq \text{null}$, *then* $h^{(i)}(v) \in V_{i+1}$.
2. $\forall u, v \in V, h^{(i)}(u) \neq h^{(i)}(v), (u, v) \in E$, *we have* $(h^{(i)}(u), h^{(i)}(v)) \in E_{i+1}$.
3. $\forall (x, y) \in E_{i+1}, (u, v) = g_{i+1}(x, y)$, *we have* $(u, v) \in E, h^{(i)}(u) = x, h^{(i)}(v) = y$.

Proof. For property 1, we can prove it by induction. It is true for $i = -1$. If $h_0(v) \neq \text{null}$, we know $h_0(v)$ must be assigned at line 19. Due to property 2 of Lemma 32.4.6, $h_0(v) \in V_1$. Suppose $\forall v \in V, h^{(i-1)}(v) \neq \text{null}$, we have $h^{(i-1)}(v) \in V_i$. For a vertex v with $h^{(i)}(v) \neq \text{null}$, according to the definition of $h^{(i)}(v)$, we know $h^{(i-1)}(v) \neq \text{null}$. Let $u = h^{(i-1)}(v)$. u must be a vertex in G_i by the induction hypothesis. Since $h^{(i)}(v) \neq \text{null}$, we know $h_i(u) \neq \text{null}$. Thus, $h_i(u)$ must be assigned at line 19. Due to property 2 of Lemma 32.4.6, $h_i(u)$ must be in G_{i+1}, which implies $h^{(i)}(v) \in V_{i+1}$.

For property 2, we can also prove it by induction. It is true for $i = -1$. If $(u, v) \in E$, then due to property 3 of Lemma 32.5.3, either both u, v are in V_0' or both u, v are in $V_0 \setminus V_0'$. If both u, v are in $V_0 \setminus V_0'$, then $h_0(u) = h_0(v) = \text{null}$. Otherwise, if $h_0(u) \neq h_0(v)$, then due to property 3 of Lemma 32.4.6, $(h_0(u), h_0(v)) \in E_1$. Now suppose we have $\forall u, v \in V$, if $h^{(i-1)}(u) \neq h^{(i-1)}(v), (u, v) \in E$, then $(h^{(i-1)}(u), h^{(i-1)}(v)) \in E_i$. Let $(u, v) \in E, h^{(i)}(u) \neq h^{(i)}(v)$. Let $x = h^{(i-1)}(u), y = h^{(i-1)}(v)$. Due to property 3 of Lemma 32.5.3, either both x, y

are in V_i' or both are in $V_i \setminus V_i'$. If $x, y \in V_i \setminus V_i'$, then $h_i(x) = h_i(y) = \text{null}$ which contradicts to $h^{(i)}(u) \neq h^{(i)}(v)$. Thus, both of $x, y \in V_i'$. Then due to property 3 of Lemma 32.4.6, $(h_i(x), h_i(v)) \in E_{i+1}$. Thus, $(h^{(i)}(u), h^{(i)}(v)) \in E_{i+1}$.

For property 3, we can prove it by induction. It is true for $i = -1$. Let us consider the case when $i = 0$. Due to property 3 of Lemma 32.4.6 and the definition of g_0, g_1, we have $\forall (x, y) \in E_1$, $(u, v) = g_1(x, y)$, $h_0(u) = x, h_0(v) = y, (u, v) \in E$. Now suppose the property holds for $i - 1$. Let $(x, y) \in E_{i+1}$. Then $g_{i+1}(x, y) = g_i(x', y')$ for some $(x', y') \in E_i, h_i(x') = x, h_i(y') = y$. Let $(u, v) = g_i(x', y')$. By the induction hypothesis $(u, v) \in E, h^{(i-1)}(u) = x', h^{(i-1)}(v) = y'$. Thus, $h^{(i)}(u) = x, h^{(i)}(v) = y$. □

Lemma 32.5.16. *Let $G = (V, E)$ be an undirected graph, m be a parameter which is at least $16|V|$, and r be a rounds parameter. If* SpanningForest(G, m, r) *(Algorithm 32.11) does not return FAIL, then $\forall i \in \{-1, 0\} \cup [r - 1]$, we can define*

$$\forall v \in V, h^{(i)}(v) = \begin{cases} v & i = -1 \\ h_i(h^{(i-1)}(v)) & h^{(i-1)}(v) \neq \text{null} \\ \text{null} & \text{otherwise.} \end{cases}$$

Let $\forall i \in \{0\} \cup [r]$, $\widehat{G}_i = (V_i, \widehat{E}_i = \{(x, y) \mid (u, v) \in \bigcup_{j=i}^{r-1} D_j, h^{(j-1)}(u) = x, h^{(j-1)}(v) = y\})$. Then $\widehat{G}_i$ is a spanning forest of G_i.

Proof. The proof is by induction. When $i = r$, since $V_r = \emptyset$, $\widehat{G}_r = (\emptyset, \emptyset)$ is a spanning forest of G_r. Now suppose $\widehat{G}_{i+1}$ is a spanning forest of G_{i+1}. Let $u, v \in V_i$. By property 2, 3 of Lemma 32.5.15, we have $\widehat{E}_i \subseteq E_i$. Thus, if $\text{dist}_{G_i}(u, v) = \infty$, then $\text{dist}_{\widehat{G}_i}(u, v) = \infty$. If $\text{dist}_{G_i}(u, v) < \infty$, there are several cases:

1. If $h_i(u) = h_i(v) = \text{null}$, then due to line 10, we know $u_u = u_v$, and $\widetilde{T}_i(u_v)$ is a spanning tree of the component which contains u, v. Thus, $\widehat{G}_i$ has a spanning tree of the component which contains u, v.

2. If $h_i(u) = h_i(v) \neq \text{null}$, then $\text{par}_i : \{x \in V_i \mid h_i(x) = h_i(v)\} \to \{x \in V_i \mid h_i(x) = h_i(v)\}$ is a tree, and $\forall y \in \{x \in V_i \mid h_i(x) = h_i(v)\}$, if $\text{par}_i(y) \neq y$, then $(y, \text{par}_i(y)) \in \widehat{E}_i$. Since $\widehat{G}_{i+1}$ does not have any cycle, there is a unique path from u to v in $\widehat{G}_i$.

3. If $h_i(u) \neq h_i(v)$, then neither of them can be null. Since $\widehat{G}_{i+1}$ is a spanning forest on G_{i+1}, there must be a unique path from $h_i(u)$ to $h_i(v)$ in $\widehat{G}_{i+1}$. Suppose the path in $\widehat{G}_{i+1}$ is $h_i(u) = p_1 - p_2 - \cdots - p_t = h_i(v)$. Then there must be a sequence of vertices in G_i, $u = p_{1,1}, p_{1,2}, p_{2,1}, p_{2,2}, \cdots, p_{t,1}, p_{t,2} = v$ such that $h_i(p_{j,1}) = h_i(p_{j,2}) = p_j$ and $(p_{j-1,2}, p_{j,1}) \in \widehat{E}_i$. Thus, there is a unique path from u to v.

Thus, $\widehat{G}_i$ is a spanning forest of G_i. □

Corollary 32.5.17 (Correctness of Algorithm 32.11)**.** *Let $G = (V, E)$ be an undirected graph, m be a parameter which is at least $16|V|$, and r be a rounds parameter. If* SpanningForest(G, m, r) *(Algorithm 32.11) does not return FAIL, then $\widehat{G}_0 = (V, F)$ is a spanning forest of G.*

Proof. Just apply Lemma 32.5.16 for $i = 0$ case. □

Lemma 32.5.18. *Let $G = (V, E)$ be an undirected graph, m be a parameter which is at least $16|V|$, and r be a rounds parameter. If* SpanningForest(G, m, r) *(Algorithm 32.11) does*

not return FAIL, then $\forall i \in \{-1, 0\} \cup [r-1]$, *we can define*

$$\forall v \in V, h^{(i)}(v) = \begin{cases} v & i = -1 \\ h_i(h^{(i-1)}(v)) & h^{(i-1)}(v) \neq \text{null} \\ \text{null} & \text{otherwise.} \end{cases}$$

$\forall i \in \{0\} \cup [r-1], v \in V_i$ *with* $\text{par}_i(v) \neq v$, *there exists* $(x, y) \in F$ *such that* $h^{(i-1)}(x) = v, h^{(i-1)}(y) = \text{par}_i(v)$.

Proof. By line 11, line 19, $\forall i \in \{0\} \cup [r-1], v \in V_i, \text{par}_i(v) \neq v$, we have $g_i(v, \text{par}_i(v)), g_i(\text{par}_i(v), v) \in D_i \subseteq F$. Since $(\text{par}_i(v), v) \in E_i$, by property 3 of Lemma 32.5.15, $(x, y) = g_i(v, \text{par}_i(v))$ satisfies $h^{(i-1)}(x) = v, h^{(i-1)}(y) = \text{par}_i(v)$. □

Theorem 32.5.19 (Correctness of Algorithm 32.12)**.** *Let* $G = (V, E)$ *be an undirected graph,* m *be a parameter which is at least* $16|V|$, *and* r *be a rounds parameter. If* SpanningForest(G, m, r) *(Algorithm 32.11) does not return FAIL, then let the output be the input of* Orientate$(\cdot)$, *(Algorithm 32.12) and the output* $\text{par} : V \to V$ *of* Orientate$(\cdot)$ *will be a rooted spanning forest (See Definition 32.5.7) of* G. *Furthermore,* $\text{dep}(\text{par}) \leq O(\text{diam}(G))^r$.

Proof. The proof is by induction. We want to show $\widehat{\text{par}}_i$ is a rooted spanning forest of G_i. When $i = r$, since $V_r = \emptyset$, the claim is true. Now suppose we have $\widehat{\text{par}}_{i+1}$ is a spanning forest of G_{i+1}. Let $\widetilde{G}_{i+1} = (\widetilde{V}_{i+1}, E_{i+1})$. It is easy to see $\widetilde{\text{par}}_{i+1} : \widetilde{V}_{i+1} \to \widetilde{V}_{i+1}$ is a spanning forest of $\widetilde{G}_{i+1}$. An observation is $\widetilde{V}_{i+1} = \{v \in V_i \mid \text{par}_i(v) = v\}$. Thus, $\widetilde{\text{par}}_{i+1}, \text{par}_i$ satisfies the condition in Lemma 32.5.12 when invoking ForestExpansion$(\widetilde{\text{par}}_{i+1}, \text{par}_i, f_{i+1})$. By Lemma 32.5.18, we know f_{i+1} also satisfies the condition in Lemma 32.5.12 when we invoke ForestExpansion$(\widetilde{\text{par}}_{i+1}, \text{par}_i, f_{i+1})$. Thus, $\widehat{\text{par}}_i$ is a rooted spanning forest of G_i due to Lemma 32.5.12.

By Lemma 32.5.12, we have $\mathrm{dep}(\widehat{\mathrm{par}}_i) \leq 16\mathrm{dep}(\widehat{\mathrm{par}}_{i+1})\,\mathrm{diam}(G)$. By induction, we have $\mathrm{dep}(\mathrm{par}) \leq O(\mathrm{diam}(G))^r$. □

Lemma 32.5.20. *Let $G = (V, E)$ be an undirected graph, m be a parameter which is at least $16|V|$, and $r \leq n$ be a round parameter. If* SpanningForest(G, m, r) *(Algorithm 32.11) does not return FAIL, then with probability at least* 0.89, $\sum_{i=0}^{r} n_i \leq 40n$.

Proof. Since $V_r \subseteq V_{r-1} \subseteq \cdots \subseteq V_0 = V$, we have $n_r \leq n_{r-1} \leq n_{r-2} \leq \cdots \leq n$. Due to line 14, line 15 and line 17, we know $\forall i \in \{0\} \cup [r-1]$, $V_{i+1} = L_i$. If $p_i < 1/2$, we know $p_i = (30\log(n) + 100)/\gamma_i$. Since $|V_{\widetilde{T}_i}(v)| \geq \gamma_i$, we can apply Lemma 32.4.3 to get $\Pr(|L_i| \leq 1.5p_in_i) \geq \Pr(|L_i| \leq 0.75n_i) \geq 1 - 1/(100n)$. By taking union bound over all $i \in \{0\} \cup [r-1]$, with probability at least 0.99, if $p_i < 0.5$, then $n_{i+1} \leq 0.75n_i$. By applying Lemma 32.4.4, condition on n_i and $p_i = \frac{1}{2}$, we have $\mathbb{E}(n_{i+1}) \leq 0.75n_i$. By Markov's inequality, with probability at 0.89, we have $\sum_{i=0}^{r} n_i \leq 40n$. □

Now let us define the total iterations of Algorithm 32.11 as the following:

Definition 32.5.8 (Total iterations)**.** Let graph $G = (V, E)$, $m \leq \mathrm{poly}(|V|)$ be a parameter which is at least $16|V|$, and r be a rounds parameter. The total number of iterations of SpanningForest(G, m, r) (Algorithm 32.11) is defined as $\sum_{i=0}^{r-1}(k_i + k'_i)$, where $\forall i \in \{0\} \cup [r-1], k_i$ denotes the number of iterations (See Definition 32.5.5) of MultipleLargeTrees(G_i, m) (see line 8), and k'_i denotes the number of iterations (See Definition 32.4.5) of TreeContraction(G'_i, par_i) (see line 17).

Theorem 32.5.21 (Success probability of Algorithm 32.11)**.** *Let $G = (V, E)$ be an undirected graph. Let $m \leq \mathrm{poly}(n)$ and $m \geq 16|V|$. Let r be a rounds parameter. Let $c > 0$*

be a sufficiently large constant. If $r \geq c \log \log_{m/n} n$*, then with probability at least* 0.79, SpanningForest(G, m, r) *(Algorithm 32.11) does not return* FAIL*. Furthermore, let* $\forall i \in \{0\} \cup [r-1], k_i$ *be the number of iterations (See Definition 32.5.5) of* MultipleLargeTrees(G_i, m) *and* k'_i *be the number of iterations (See Definition 32.4.5) of* TreeContraction$(G'_i, \mathrm{par}_i : V'_i \to V'_i)$*. Let* $c_1 > 0$ *be a sufficiently large constant. If* $m \geq c_1 n \log^8 n$*, then with probability at least* 0.99, $\sum_{i=0}^{r-1} k_i + k'_i \leq O(\min(\log(\mathrm{diam}(G)) \log \log_{\mathrm{diam}(G)}(n),\ r \log(\mathrm{diam}(G))))$*. If* $m < c_1 n \log^8 n$*, then with probability at least* 0.98, $\sum_{i=0}^{r-1} k'_i + k_i \leq O(\min(\log(\mathrm{diam}(G)) \log \log_{\mathrm{diam}(G)}(n) + (\log \log n)^2, r \log(\mathrm{diam}(G))))$.

Proof. Due to Lemma 32.5.20, with probability at last 0.89, we have $\forall i \in [r], n'_i \leq 40n$. Thus, we can condition on that SpanningForest(G, m, r) will not fail on line 21.

Due to Lemma 32.5.6, $k_i \leq O(\log(\mathrm{diam}(G_i))) \leq O(\log(\mathrm{diam}(G)))$. Due to Corollary 32.4.8 and Lemma 32.5.14, $k'_i \leq O(\log(\mathrm{diam}(G)))$. Thus, $\sum_{i \in \{0\} \cup [r-1]} k'_i + k_i \leq O(r \log(\mathrm{diam}(G)))$.

Since $V_r \subseteq V_{r-1} \subseteq V_{r-2} \subseteq \cdots \subseteq V_0 = V$, we have $n_r \leq n_{r-1} \leq n_{r-2} \leq \cdots \leq n$. Due to line 14, line 15 and line 17, we know $\forall i \in \{0\} \cup [r-1]$, $V_{i+1} = L_i$. If $p_i < 1/2$, we know $p_i = (30 \log(n) + 100)/\gamma_i$. Since $|V_{\widetilde{T}_i}(v)| \geq \gamma_i$, we can apply Lemma 32.4.3 to get $\Pr(|L_i| \leq 1.5 p_i n_i) \geq 1 - 1/(100n)$. By taking union bound over all $i \in \{0\} \cup [r-1]$, with probability at least 0.99, if $p_i < 0.5$, then $n_{i+1} \leq 1.5 p_i n_i \leq 0.75 n_i$. Let $\mathcal{E}$ be the event that $\forall i \in \{0\} \cup [r-1]$, if $p_i < 0.5$, then $n_{i+1} \leq 1.5 p_i n_i$. Now, we suppose $\mathcal{E}$ happens.

If $p_0 = 0.5$, then $m \leq n \cdot (600 \log n)^8$. By applying Lemma 32.4.4, $\mathbb{E}(n_{i+1}) = \mathbb{E}(|L_i|) \leq 0.75\, \mathbb{E}(n_i) \leq \cdots \leq 0.75^{i+1} n$. By Markov's inequality, when $i^* \geq 8 \log(6000 \log n)/\log(4/3)$, with probability at least 0.99, $n_{i^*} \leq n/(600 \log n)^8$ and thus $p_{i^*} < 0.5$. Condition on this

event and $\mathcal{E}$, we have

$$
\begin{aligned}
n_r &\le \frac{\left(\frac{\left(\frac{n_{i^*}^{1.25}}{m^{0.25}}(45\log n+150)\right)^{1.25}}{m^{0.25}}(45\log n+150)\right)^{\cdots}}{\cdots} && \text{(Apply } r'=r-i^* \text{ times)}\\
&= n_{i^*}/(m/n_{i^*})^{1.25^{r'}-1}\cdot(45\log n+150)^{4\cdot(1.25^{r'}-1)}\\
&\le n/\left(m/\left(n_{i^*}(45\log n+150)^4\right)\right)^{1.25^{r'}-1}\\
&\le n/\left(m/\left(n_{i^*}(45\log n+150)^4\right)\right)^{1.25^{r'}/2} \le n/(m/n)^{1.25^{r'}/2} \le 1/2,
\end{aligned}
$$

where the second inequality follows by $n_{i^*} \le n$, the third inequality follows by $r' \ge 5$, the forth inequality follows by $n_{i^*} \le n/(600\log n)^8$, and the last inequality follows by $r' \ge \frac{2}{\log 1.25}\log\log_{m/n}(2n)$. Since $16n \le m \le n\cdot(600\log n)^8, \log\log_{m/n} n = \Theta(\log\log n)$. Let $c > 0$ be a sufficiently large constant. Thus, when $r \ge c\log\log_{m/n} n \ge i^* + r' = 8\log(6000\log n)/\log(4/3) + \frac{2}{\log 1.25}\log\log_{m/n}(2n)$, with probability at least 0.98, $n_r = 0$ implies that SpanningForest(G, m, r) will not fail. Due to Lemma 32.5.6, we have $k_i \le$

$O(\min(\log(m/n_i), \log(\mathrm{diam}(G))))$. Thus,

$$
\begin{aligned}
&\sum_{i=0}^{r-1} k_i \\
&= \sum_{i=0}^{i^*} k_i + \sum_{i=i^*+1}^{r-1} k_i \\
&\le O\left((\log\log n)^2\right) + \sum_{i=i^*+1}^{r-1} k_i \\
&\le O\left((\log\log n)^2\right) + \sum_{i:i\ge i^*+1, m/n_i \le \mathrm{diam}(G)} k_i + \sum_{i:i\le r, m/n_i > \mathrm{diam}(G)} k_i \\
&\le O\left((\log\log n)^2\right) + O\left(\sum_{i=0}^{\lceil \log_{1.25}\log_2(\mathrm{diam}(G))\rceil} \log(2^{1.25^i})\right) + O\left(\sum_{i=0}^{\lceil \log_{1.25}\log_{\mathrm{diam}(G)}(m)\rceil} \log(\mathrm{diam}(G))\right) \\
&\le O\left((\log\log n)^2\right) + O(\log(\mathrm{diam}(G))) + O(\log(\mathrm{diam}(G))\log\log_{\mathrm{diam}(G)}(n)) \\
&\le O(\log(\mathrm{diam}(G))\log\log_{\mathrm{diam}(G)}(n) + (\log\log(n))^2),
\end{aligned}
$$

where the first inequality follows by $i^* = O(\log\log n)$ and $\forall i \le [i^*], m/n_i \le \mathrm{poly}(\log n)$, the third inequality follows by $m/n_{i+1} \ge (m/n_i)^{1.25}/(45\log n + 100) \ge (m/n_i)^{1.125}$. Due to Corollary 32.4.8 and Lemma 32.5.14, we also have $k'_i \le O(\min(\log(m/n_i), \log(\mathrm{diam}(G))))$. Then, by the same argument, we have $\sum_{i=0}^{r-1} k'_i = O(\log(\mathrm{diam}(G))\log\log_{\mathrm{diam}(G)}(n) + (\log\log(n))^2)$.

If $m > n \cdot (600\log n)^8$, then $\forall i \in \{0\} \cup [r-1]$, we have $p_i < 0.5$. Since $\mathcal{E}$ happens.

We have:

$$
\begin{aligned}
n_r &\le \frac{\left(\frac{\left(\frac{n^{1.25}}{m^{0.25}}(45\log n+150)\right)^{1.25}}{m^{0.25}}(45\log n+150)\right)^{\cdots}}{\cdots} && \text{(Apply } r \text{ times)} \\
&= \frac{n^{1.25^r}}{m^{1.25^r-1}}(45\log n+150)^{4\cdot(1.25^r-1)} \\
&= n/(m/n)^{1.25^r-1}\cdot(45\log n+150)^{4\cdot(1.25^r-1)} \\
&= n/\left(m/\left(n(45\log n+150)^4\right)\right)^{1.25^r-1} \\
&\le n/\left(m/\left(n(45\log n+150)^4\right)\right)^{1.25^{r/2}} \\
&\le n/\left(m/\left(n(200\log n)^4\right)\right)^{1.25^{r/2}} \\
&\le \frac{1}{2},
\end{aligned}
$$

where the second inequality follows by $r \ge 5$, the third inequality follows by $45\log n + 150 \le 200\log n$, and the last inequality follows by

$$
r \ge c\log\log_{m/n} n \ge 2\log_{1.25}\log_{(m/n)^{1/2}} 2n \ge 2\log_{1.25}\log_{m/(n(200\log n)^4)} 2n,
$$

for a sufficiently large constant $c > 0$. Since n_r is an integer, n_r must be 0 when $n_r \le 1/2$. SpanningForest(G, m, r) will succeed with probability at least 0.99. Due to Lemma 32.5.6, we have $k_i \le O(\min(\log(m/n_i), \log(\mathrm{diam}(G))))$. Thus,

$$
\begin{aligned}
\sum_{i=0}^{r-1} k_i &\le \sum_{m/n_i \le \mathrm{diam}(G)} k_i + \sum_{m/n_i > \mathrm{diam}(G)} k_i \\
&\le O\left(\sum_{i=0}^{\lceil\log_{1.25}\log_2(\mathrm{diam}(G))\rceil} \log(2^{1.25^i})\right) + O\left(\sum_{i=0}^{\lceil\log_{1.25}\log_{\mathrm{diam}(G)}(m)\rceil} \log(\mathrm{diam}(G))\right) \\
&\le O(\log(\mathrm{diam}(G))) + O(\log(\mathrm{diam}(G))\log\log_{\mathrm{diam}(G)}(n)),
\end{aligned}
$$

where the second inequality follows by $m/n_{i+1} \geq (m/n_i)^{1.25}/(45 \log n + 100) \geq (m/n_i)^{1.125}$.

Due to Corollary 32.4.8 and Lemma 32.5.14, we also have $k'_i \leq O(\min(\log(m/n_i), \log(\mathrm{diam}(G))))$.

Then, by the same argument, we have $\sum_{i=0}^{r-1} k'_i = O(\log(\mathrm{diam}(G))) + O(\log(\mathrm{diam}(G)) \log \log_{\mathrm{diam}(G)}(n))$.

□

32.6 Depth-First-Search Sequence for Tree and Applications

32.6.1 Lowest Common Ancestor and Multi-Paths Generation

Given a rooted forest induced by $\text{par} : V \to V$ which is a set of parent pointers (See Definition 32.4.2) on V, and a set of q queries $Q = \{(u_1, v_1), (u_2, v_2), \cdots, (u_q, v_q) \mid u_i, v_i \in V\}$, we show an algorithm which can return a mapping $\text{lca} : Q \to (V \cup \{\text{null}\}) \times (V \cup \{\text{null}\}) \times (V \cup \{\text{null}\})$ such that $\forall (u_i, v_i) \in Q, (p, p_{u_i}, p_{v_i}) = \text{lca}(u_i, v_i)$ satisfies the following properties:

1. If $\text{par}^{(\infty)}(u_i) = \text{par}^{(\infty)}(v_i)$, then p is the lowest ancestor of u_i and v_i. Otherwise $p = p_{u_i} = p_{v_i} = \text{null}$.
2. Suppose $p \neq \text{null}$. If $p \neq u_i$, then p_{u_i} is an ancestor of u_i and $\text{part}(p_{u_i}) = p$. Otherwise, $p_{u_i} = \text{null}$.
3. Suppose $p \neq \text{null}$. If $p \neq v_i$, then p_{v_i} is an ancestor of v_i and $\text{part}(p_{v_i}) = p$. Otherwise, $p_{v_i} = \text{null}$.

Before we describe the algorithms, let us formally define *ancestor* and the *lowest common ancestor*.

Definition 32.6.1 (Ancestor)**.** Let $\text{par} : V \to V$ be a set of parent pointers (See Definition 32.4.2) on a vertex set V. For $u, v \in V$, if $\exists k \in \mathbb{Z}_{\geq 0}$ such that $u = \text{par}^{(k)}(v)$, then u is an ancestor of v.

Definition 32.6.2 (Common ancestor and the lowest common ancestor)**.** $\text{par} : V \to V$ be a set of parent pointers (See Definition 32.4.2) on a vertex set V. For $u, v \in V$, if w is an ancestor of u and is also an ancestor of v, then w is a common ancestor of (u, v). If a common

ancestor w of (u, v) satisfies $\mathrm{dep}_{\mathrm{par}}(w) \geq \mathrm{dep}_{\mathrm{par}}(x)$ for any common ancestor x of (u, v), then w is the lowest common ancestor (LCA) of (u, v).

Definition 32.6.3 (Path between two vertices)**.** $\mathrm{par} : V \to V$ be a set of parent pointers (See Definition 32.4.2) on a vertex set V. For $u, v \in V$, if $\mathrm{par}^{(\infty)}(u) = \mathrm{par}^{(\infty)}(v)$, then the path from u to v is a sequence $(x_1, x_2, \cdots, x_j, x_{j+1}, \cdots x_k)$ such that $\forall i \neq i' \in [k], x_i \neq x_{i'}, x_1 = u, x_k = v, x_j$ is the lowest common ancestor of (u, v), $\forall i \in [j-1], \mathrm{part}(x_i) = x_{i+1}$, and $\forall i \in \{j+1, j+2, \cdots, k\}, \mathrm{part}(x_i) = x_{i-1}$.

The algorithm which can compute the lowest common ancestor is described in Algorithm 32.13.

Lemma 32.6.1. *Let* $\mathrm{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*. Let* $Q = \{(u_1, v_1), (u_2, v_2), \cdots, (u_q, v_q)\}$ *be a set of* q *pairs of vertices, and* $\forall i \in [q], u_i \neq v_i$*. Let* $\mathrm{lca} = \mathrm{LCA}(\mathrm{par}, Q)$ *(Algorithm 32.13). Then for any* $(u, v) \in Q$*,* $(p, p_u, p_v) = \mathrm{lca}(u, v)$ *satisfies the following properties:*

1. *If* $\mathrm{par}^{(\infty)}(u) \neq \mathrm{par}^{(\infty)}(v)$*, then* $p = p_u = p_v = \mathrm{null}$.
2. *If* u *(or* v*) is the lowest common ancestor of* (u, v)*, then* $p = u, p_u = \mathrm{null}, p_v \neq u$ *is an ancestor of* v *such that* $\mathrm{part}(p_v) = u$ *(or* $p = v, p_v = \mathrm{null}, p_u \neq v$ *is an ancestor of* u *such that* $\mathrm{part}(p_u) = v$*.)*
3. *If neither* u *nor* v *is the lowest common ancestor of* (u, v) *and* $\mathrm{par}^{(\infty)}(u) = \mathrm{par}^{(\infty)}(v)$*, then* p *is the lowest common ancestor of* (u, v)*,* $p_u \neq p$ *is an ancestor of* u*,* $p_v \neq p$ *is an ancestor of* v*, and* $\mathrm{part}(p_u) = \mathrm{part}(p_v) = p$.

Proof. According to Lemma 32.5.7, r should be at most $\lceil \log(\text{dep}(\text{par})+1) \rceil$, $\text{dep}_{\text{par}} : V \to \mathbb{Z}_{\geq 0}$ records the depth of every vertex in V, and $\forall i \in \{0\} \cup [r], v \in V$ $g_i(v) = \text{par}^{(2^i)}(v)$. Then property 1 follows by line 5 directly.

Then for all $(u, v) \in Q$ with $\text{par}^{(\infty)}(u) = \text{par}^{(\infty)}(v)$, either $(u, v) \in Q'$ or $(v, u) \in Q'$. For each $(u, v) \in Q'$, we have $\text{dep}_{\text{par}}(u) \geq \text{dep}_{\text{par}}(v)$. For all $(u, v) \in Q'$, with $\text{dep}_{\text{par}}(u) > \text{dep}_{\text{par}}(v)$, by induction we can prove that $\forall i \in \{0\} \cup [r-1], (x, y) = h_i(u, v)$ satisfies that x is an ancestor of u, $y = v$, $\text{dep}_{\text{par}}(x) > \text{dep}_{\text{par}}(v)$ and $\text{par}^{(2^i)}(x)$ is an ancestor of v. Thus, for $(p, p_u, p_v) = \text{lca}(u, v)$, if v is the lowest common ancestor of u, then we have $p = v, p_u = h_0(u), p_v = \text{null}$. In this case, $h_0(u)$ is an ancestor of u, and $\text{dep}_{\text{par}}(u) = \text{dep}_{\text{par}}(v) + 1, \text{part}(h_0(u)) = v$. Thus, property 2 holds.

For all $(u, v) \in Q$ with $\text{par}^{(\infty)}(u) = \text{par}^{(\infty)}(v)$, if neither u nor v is the lowest common ancestor of (u, v), then we know either (u, v) or (v, u) is in Q''. Now let $(u, v) \in Q''$. We have $\text{dep}_{\text{par}}(h'_r(u)) = \text{dep}_{\text{par}}(h'_r(v)), h'_r(u) \neq h'_r(v)$, and $h'_r(u), h'_r(v)$ are ancestors of u, v respectively. We can prove by induction to get $\forall i \in \{0\} \cup [r], h'_i(u) \neq h'_i(v)$ and $\text{par}^{(2^i)}(h'_i(u)) = \text{par}^{(2^i)}(h'_i(v))$ is a common ancestor of (u, v). Thus, $p = \text{part}(h'_0(u)) = \text{part}(h'_0(v))$ is the lowest common ancestor of (u, v), and $\text{dep}_{\text{par}}(h'_0(u)) = \text{dep}_{\text{par}}(h'_0(v)) = \text{dep}_{\text{par}}(p) + 1$. Since $p_u = h'_0(u), p_v = h'_0(v)$, property 3 holds. □

In Algorithm 32.14, we show a generalization of Algorithm 32.8 such that we can find multiple vertex-to-ancestor paths simultaneously.

The following lemma claims the properties of the outputs of Algorithm 32.14. And the proof is similar to the proof of Lemma 32.5.9.

Lemma 32.6.2. *Let* $\text{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*. Let* $Q = \{(u_1, v_1), (u_2, v_2), \cdots, (u_q, v_q)\} \subseteq V \times V$ *satisfy* $\forall j \in [q]$, v_j *is an ancestor (See Definition 32.6.1) of* u_j *in* par*. Let* $(\text{dep}_{\text{par}}, \{P_j \mid j \in [q]\}) = \textsc{MultiPath}(\text{par}, Q)$ *(Algorithm 32.14). Then* $\text{dep}_{\text{par}} : V \to \mathbb{Z}_{\geq 0}$ *records the depth of every vertex in* V *and* $\forall j \in [q], P_j \subseteq V$ *is the set of all vertices on the path from* u_j *to* v_j*, i.e.* $P_j = \{v \in V \mid \exists k_1, k_2 \in \mathbb{Z}_{\geq 0}, v = \text{par}^{(k_1)}(u_j), v_j = \text{par}^{(k_2)}(v)\}$*. Furthermore,* r *should be at most* $\lceil \log(\text{dep}(\text{par}) + 1) \rceil$*.*

Proof. By Lemma 32.5.7, since $(r, \text{dep}_{\text{par}}, \{g_i \mid i \in \{0\} \cup [r]\}) = \textsc{FindAncestors}(\text{par})$, we know r should be at most $\lceil \log(\text{dep}(\text{par}) + 1) \rceil$, $\text{dep}_{\text{par}} : V \to \mathbb{Z}_{\geq 0}$ records the depth of every vertex in V, and $\forall i \in \{0\} \cup [r], v \in V$ $g_i(v) = \text{par}^{(2^i)}(v)$.

For $j \in [q]$, let us prove that P_j is the vertex set of all the vertices on the path from u_j to its ancestor v_j. We use divide-and-conquer to get P_j. The following claim shows that $S_j^{(i)}$ is a set of segments which is a partition of the path from u_j to v_j, and each segment has length at most 2^{r-i}.

Claim 32.6.3. $\forall i \in \{0\} \cup [r], j \in [q]$ $S_j^{(i)}$ *satisfies the following properties:*

1. $\exists (x, y) \in S_j^{(i)}$ *such that* $x = u_j$*.*
2. $\exists (x, y) \in S_j^{(i)}$ *such that* $y = v_j$*.*
3. $\forall (x, y) \in S_j^{(i)}$, $\text{dep}_{\text{par}}(y) - \text{dep}_{\text{par}}(x) \leq 2^{r-i}$*.*
4. $\forall (x, y) \in S_j^{(i)}$*, if* $y \neq v_j$*, then* $\exists (x', y') \in S_j^{(i)}, x' = y$*.*
5. $\forall (x, y) \in S_j^{(i)}$, $\exists k \in \mathbb{Z}_{\geq 0}, \text{par}^{(k)}(x) = y$*.*

Proof. We fix a $j \in [q]$. Our proof is by induction. According to line 4, all the properties hold when $i = 0$. Suppose all the properties hold for $i - 1$. For property 1, by induction we know there exists $(x, y) \in S_j^{(i-1)}$ such that $x = u_j$. Then by line 9 and line 10, there must be an (x, y') in $S_j^{(i)}$. For property 2, by induction we know there exists $(x, y) \in S_j^{(i-1)}$ such that $y = v_j$. Thus, there must be an (x', y) in $S_j^{(i)}$. For property 3, if (x, y) is added into $S_j^{(i)}$ by line 10, then $\mathrm{dep}_{\mathrm{par}}(x) - \mathrm{dep}_{\mathrm{par}}(y) \le 2^{r-i}$. Otherwise, in line 9, we have $\mathrm{dep}_{\mathrm{par}}(x) - \mathrm{dep}_{\mathrm{par}}(g_{r-i}(x)) \le 2^{r-i}, \mathrm{dep}_{\mathrm{par}}(g_{r-i}(x)) - \mathrm{dep}_{\mathrm{par}}(y) \le 2^{r-i+1} - 2^{r-i} = 2^{r-i}$. For property 4, if (x, y) is added into $S_j^{(i)}$ by line 10, then by induction there is $(y, y') \in S_j^{(i-1)}$, and thus by line 10 and line 9, there must be $(y, y'') \in S_j^{(i)}$. Otherwise, in line 9 will generate two pairs $(x, g_{r-i}(x)), (g_{r-i}(x), y)$. For $(x, g_{r-i}(x))$, the property holds. For $(g_{r-i}(x), y)$, there must be $(y, y') \in S_{i-1}$ and thus there should be $(y, y'') \in S^{(i)}$. For property 5, since $g_{r-i}(x) = \mathrm{par}^{(r-i)}(x)$, for all pairs generated by line 9 and line 10, the property holds. □

By Claim 32.6.3, we know

$$
\begin{aligned}
S_j^{(r)} = \{ & \\
& (u_j, \mathrm{part}(u_j)), \\
& \left(\mathrm{part}(u_j), \mathrm{par}^{(2)}(u_j)\right), \\
& \left(\mathrm{par}^{(2)}(u_j), \mathrm{par}^{(3)}(u_j)\right), \\
& \cdots, \\
& \left(\mathrm{par}^{(\mathrm{dep}_{\mathrm{par}}(u_j) - \mathrm{dep}_{\mathrm{par}}(v_j) - 1)}(u_j), \mathrm{par}^{(\mathrm{dep}_{\mathrm{par}}(u_j) - \mathrm{dep}_{\mathrm{par}}(v_j))}(u_j)\right) \\
\} & .
\end{aligned}
$$

Thus, P_j is the set of all the vertices on the path from u_j to an ancestor v_j. □

32.6.2 Depth-First-Search Sequence for a Tree

Since we can use our spanning tree algorithm to get a rooted tree, in this section, we only consider how to get a Depth-First-Search (DFS) sequence for a rooted tree. Before we go to the details, let us firstly give formal definitions of some useful concepts.

Definition 32.6.4 (Children in the forest)**.** Given a set of parent pointers (See Definition 32.4.2) $\text{par} : V \to V$ on a vertex set V. $\forall u, v \in V, u \neq v$ if $\text{part}(u) = v$, then we say u is a child of v. $\forall v \in V$, we can define $\text{child}_{\text{par}}(v)$ as the set of all children of v, i.e. $\text{child}_{\text{par}}(v) = \{u \in V \mid u \neq v, \text{part}(u) = v\}$. Furthermore, if u is the k^{th} smallest vertex in the children set $\text{child}_{\text{par}}(v)$, then we say $\text{rank}_{\text{par}}(u) = k$, or u is the k^{th} child of v. If $\text{part}(v) = v$, then $\text{rank}_{\text{par}}(v) = 1$. We use $\text{child}_{\text{par}}(v, k)$ to denote the k^{th} child of v.

For simplicity of the notation, if $\text{par} : V \to V$ is clear in the context, we just use $\text{child}(v), \text{rank}(v)$ and $\text{child}(v, k)$ to denote $\text{child}_{\text{par}}(v), \text{rank}_{\text{par}}(v)$ and $\text{child}_{\text{par}}(v, k)$ respectively.

Definition 32.6.5 (Leaves in the forest)**.** Given a set of parent pointers (See Definition 32.4.2) $\text{par} : V \to V$ on a vertex set V. If $\text{child}_{\text{par}}(v) = \emptyset$, then v is called a leaf. The set of all the leaves of par is defined as $\text{leaves}(\text{par}) = \{v \mid \text{child}_{\text{par}}(v) = \emptyset\}$.

Definition 32.6.6 (Subtree)**.** Let $\text{par} : V \to V$ be a set of parent pointers (See Definition 32.4.2) on a vertex set V. Let $v \in V, V' = \{u \in V \mid v$ is an ancestor (Definition 32.6.1) of $u\}$. Let $\text{par}' : V' \to V'$ be a set of parent pointers on V'. If $\forall u \in V' \setminus \{v\}, \text{par}'(u) = \text{part}(u)$, and $\text{par}'(v) = v$, then we say par' is the subtree of v in par. For $u \in V'$, we say u is in the subtree of v.

Definition 32.6.7 (Depth-First-Search (DFS) sequence)**.** Let par : $V \to V$ be a set of parent pointers (See Definition 32.4.2) on a vertex set V. Let v be a vertex in V. If v is a leaf (See Definition 32.6.5) in par, then the DFS sequence of the subtree (See Definition 32.6.6) of v is (v). Otherwise the DFS sequence of the subtree of v in par is recursively defined as

$$(v, a_{1,1}, a_{1,2}, \cdots, a_{1,n_1}, v, a_{2,1}, a_{2,2}, \cdots, a_{2,n_2}, v, \cdots, a_{k,1}, a_{k,2}, \cdots, a_{k,n_k}, v),$$

where $k = |\operatorname{child}(v)|$ is the number of children (See Definition 32.6.4) of v, and $\forall i \in [k], (a_{i,1}, \cdots, a_{i,n_i})$ is the DFS sequence of the subtree of $\operatorname{child}(v, i)$, i.e. the i^{th} child of v.

If $\forall u \in V, \text{par}^{(\infty)}(u) = v$, then the subtree of v is exactly par, and thus the DFS sequence of the subtree of v is also called the DFS sequence of par.

Here are some useful facts of the above defined DFS sequence.

Fact 32.6.4. *Let* par : $V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*, and* par *has a unique root. Let* $A = (a_1, a_2, \cdots, a_m)$ *be the DFS sequence (See Definition 32.6.7) of* par*. Then,* A *satisfies the following properties:*

1. $\forall v \in V$, v *appears exactly* $|\operatorname{child}(v)| + 1$ *times in* A*.*
2. *If* a_i *is the* k^{th} *time that* v *appears, and* a_j *is the* $(k+1)^{th}$ *time that* v *appears. Then* $(a_{i+1}, a_{i+2}, \cdots, a_{j-1})$ *is the DFS sequence of the subtree of* $\operatorname{child}(v, k)$ *(See Definition 32.6.4), the* k^{th} *child of* v*. Furthermore,* a_{i+1} *is the first time that* $\operatorname{child}(v, k)$ *appears, and* a_{j-1} *is the last time of* $\operatorname{child}(v, k)$ *appears.*
3. *If* a_i *is the first time that* v *appears, and* a_j *is the last time that* v *appears. Then* $(a_i, a_{i+1}, \cdots, a_j)$ *is the DFS sequence of the subtree of* v*.*

4. $m = 2|V| - 1$.

Proof. The property 1, 2, 3 directly follows by Definition 32.6.7.

For property 4, notice that $\forall u \in V, \text{part}(u) \neq u$, u can only be a child of $\text{part}(u)$. Thus, $\sum_{v \in V}(|\text{child}(v)| + 1) = |V| - 1 + |V| = 2|V| - 1$. □

Due to the above fact, if v is a leaf in par, then it will only once in the DFS sequence. Thus, we are able to determine the order of all the leaves.

Definition 32.6.8 (The order of the leaves)**.** Let $\text{par} : V \to V$ be a set of parent pointers (See Definition 32.4.2) on a vertex set V, and par has a unique root. Let $A = (a_1, a_2, \cdots, a_m)$ be the DFS sequence (See Definition 32.6.7) of par . Let u, v be two leaves (See definition 32.6.5) of par . If u appears before v in A, then we say $u <_{\text{par}} v$.

32.6.2.1 Leaf Sampling

Given a set of rooted trees, our goal is to sample a set of leaves for each tree, and to give an order of those sampled leaves. The algorithm is shown in Algorithm 32.15.

Lemma 32.6.5. *Let* $\text{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*, and* par *has a unique root. Let* $m > 0, \delta \in (0, 1)$ *be parameters, and let* $|V| \leq m^{1/\delta}$*. Let* $(a_1, a_2, \cdots, a_s) = \textsc{LeafSampling}(\text{par}, m, \delta)$ *(Algorithm 32.15). Then it has following properties:*

1. $a_1 <_{\text{par}} a_2 <_{\text{par}} \cdots <_{\text{par}} a_s$.
2. *If* $|V| \leq m$ *or* $|\text{leaves}(\text{par})| \leq 8\lceil m^{1/3} \rceil$*, then* $\{a_1, a_2, \cdots, a_s\} = \text{leaves}(\text{par})$*. Otherwise, with probability at least* $1 - 1/(100m^{5/\delta})$*,* $\forall v \in \text{leaves}(\text{par}) \setminus \{a_1\}$*, there is a vertex*

$w \in \{a_1, a_2, \cdots, a_s\}$ *such that* $w <_{\text{par}} v$ *and the number of leaves between* w *and* v *is at most* $|\operatorname{leaves}(\text{par})|/\lceil m^{1/3} \rceil$, *i.e.* $|\{u \in \operatorname{leaves}(\text{par}) \mid w <_{\text{par}} u <_{\text{par}} v\}| \leq |\operatorname{leaves}(\text{par})|/\lceil m^{1/3} \rceil$.

3. *If* $|V| > m$ *and* $|\operatorname{leaves}(\text{par})| > 8\lceil m^{1/3} \rceil$, *then with probability at least* $1 - 1/(100m^{5/\delta})$, $s = |S| = |\{a_1, a_2, \cdots, a_s\}| \leq 960\lceil m^{1/3} \rceil (1 + \log(m)/\delta)$.

Proof. Firstly, let us focus on property 1. According to line 11 to line 13 and Lemma 32.5.7, we know $\forall k \in \mathbb{Z}_{\geq 0} \operatorname{rank}_{\text{par}}(\text{par}^{(k)}(a_1)) = 1$, and $\text{par}'(a_1) = a_1$ which implies that a_1 is a leaf. Due to the definition of 32.6.7, we know that a_1 must be the first leaf appeared in the DFS sequence of par . We can prove the property by induction. Suppose we already have $a_1 <_{\text{par}} a_2 <_{\text{par}} \cdots <_{\text{par}} a_{i-1}$. According to line 19 and Lemma 32.6.1, p_{a_{i-1},a_i} is the LCA of (a_{i-1}, a_i). $p_{a_{i-1}a_i,a_{i-1}}$ is a child of p_{a_{i-1},a_i} and is an ancestor of a_{i-1}. $p_{a_{i-1}a_i,a_i}$ is a child of p_{a_{i-1},a_i} and is an ancestor of a_i. By Fact 32.6.4, since $\operatorname{rank}(p_{a_{i-1}a_i,a_{i-1}}) < \operatorname{rank}(p_{a_{i-1}a_i,a_i})$, we have $a_{i-1} <_{\text{par}} a_i$. To conclude, we have $a_1 <_{\text{par}} a_2 <_{\text{par}} \cdots <_{\text{par}} a_s$.

For property 2, if $|V| \leq m$ or $|\operatorname{leaves}(\text{par})| \leq 8\lceil m^{1/3} \rceil$, then by line 6 and line 7, we know $\{a_1, a_2, \cdots, a_s\} = \operatorname{leaves}(\text{par})$.

Now consider the case when $|V| > m$ and $|\operatorname{leaves}(\text{par})| > 8\lceil m^{1/3} \rceil$. Let $t = \lceil m^{1/3} \rceil$. Let $\operatorname{leaves}(\text{par}) = \{u_1, u_2, \cdots, u_q\}$, and let $u_1 <_{\text{par}} u_2 <_{\text{par}} \cdots <_{\text{par}} u_q$. Let us partition $u_1, \cdots, u_q$ into $4 \cdot t$ groups $G_1 = \{u_1, u_2, \cdots, u_{\lfloor q/(4t) \rfloor}\}, G_2 = \{u_{\lfloor q/(4t) \rfloor + 1}, u_{\lfloor q/(4t) \rfloor + 2}, \cdots, u_{2 \cdot \lfloor q/(4t) \rfloor}\}, \cdots, G_{4t} = \{u_{(4t-1)\lfloor q/(4t) \rfloor + 1}, u_{(4t-1)\lfloor q/(4t) \rfloor + 2}, \cdots, u_q\}$. Then each group has size at least $q/(8t)$ and at most

$q/(2t)$. For a certain G_i, by Chernoff bound, we have

$$\begin{aligned}
&\Pr\left(|G_i \cap S| \leq \frac{1}{2} \cdot \frac{q}{8t} \cdot p\right) \\
\leq\ &\exp\left(-\frac{1}{8} \cdot \frac{q}{8t} \cdot p\right) \\
\leq\ &1/(100m^{10/\delta})
\end{aligned}$$

where the last inequality follows by $p = \min(1, (10 + 10\log(m)/\delta) \cdot 64t/q)$. Notice that $q \leq |V| \leq m^{1/\delta}$. We can take union bound over all G_i. Then with probability at least $1 - 1/(100m^{5/\delta})$, $\forall i \in [4t], G_i \cap S \neq \emptyset$. Thus, $\forall v \in \text{leaves(par)}$, there is a vertex $w \in \{a_1, a_2, \cdots, a_s\}$ such that $w <_{\text{par}} v$ and the number of leaves between w and v is at most $|\text{leaves(par)}|/\lceil m^{1/3} \rceil$, i.e. $|\{u \in \text{leaves(par)} \mid w <_{\text{par}} u <_{\text{par}} v\}| \leq |\text{leaves(par)}|/\lceil m^{1/3} \rceil$.

For property 3, by applying Chernoff bound, we have

$$\begin{aligned}
&\Pr\left(|S \cap \text{leaves(par)}| \geq \frac{3}{2}|\text{leaves(par)}| \cdot p\right) \\
\leq\ &\exp\left(-\frac{1}{12} \cdot |\text{leaves(par)}| \cdot p\right) \\
\leq\ &1/(100m^{10/\delta})
\end{aligned}$$

where the last inequality follows by $p = \min(1, (10 + 10\log(m)/\delta) \cdot 64t/|\text{leaves(par)}|)$.

Since $\frac{3}{2}|\text{leaves(par)}| \cdot p \leq 960\lceil m^{1/3} \rceil (1 + \log(m)/\delta)$, we complete the proof. □

32.6.2.2 DFS Subsequence

Let $\text{par} : V \to V$ be a set of parent pointers on a vertex set V, and par has a unique root v. Let $\{u_1, u_2, \cdots, u_q\} = \text{leaves(par)}$, and $u_1 <_{\text{par}} u_2 <_{\text{par}} \cdots <_{\text{par}} u_q$. One observation is that the DFS sequence of par can be generated in the following way:

1. The first part of the DFS sequence is the path from v to u_1.

2. Then it follows by the path from part(u_1) to the LCA of (u_1, u_2), the path from one of the child of the LCA of (u_1, u_2) to u_2, the path from part(u_2) to the LCA of (u_2, u_3), the path from one of the child of the LCA of (u_2, u_3) to $u_3, \cdots$, the path from one of the child of the LCA of (u_{q-1}, u_q) to u_q.

3. The last part of the DFS sequence is a path from part(u_q) to v.

Fact 32.6.6. *Let* par $: V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*, and* par *has a unique root* v*. Let* $\{u_1, u_2, \cdots, u_q\} =$ leaves(par) *(See Definition 32.6.5), and* $u_1 <_{\text{par}} u_2 <_{\text{par}} \cdots <_{\text{par}} u_q$*. Let* $A = (a_1, a_2, \cdots, a_m)$ *be the DFS sequence (See Definition 32.6.7) of* par*. Then,*

1. *If* u_1 *appears at* a_i*, then* $(a_1, a_2, \cdots, a_i)$ *is the path from* v *to* u_1*.*

2. $\forall i \in [q-1]$*, if* u_i *appears at* a_j*, and* u_{i+1} *appears at* a_k*, then* $\exists j < t < k$ *such that* a_t *is the LCA of* (u_i, u_{i+1})*. In addition,* $(a_j, a_{j+1}, \cdots, a_t)$ *is the path from* a_j *to* a_t*, and* $(a_t, a_{t+1}, \cdots, a_k)$ *is the path from* a_t *to* a_k*.*

3. *If* u_q *appears at* a_i*, then* $(a_i, a_{i+1}, \cdots, a_m)$ *is the path from* u_q *to* v*.*

Proof. Property 1, 3 follows by the definition of DFS sequence (See Definition 32.6.7) and a simple induction.

Now consider property 2. Since A is a DFS sequence, $\forall l \in \{j, j+1, \cdots, k-1\}$, either part$(a_l) = a_{l+1}$ or part$(a_{l+1}) = a_l$. Thus, the path between u_i and u_{i+1} is a subsequence of

$(a_j, a_{j+1}, \cdots, a_k)$. If $\text{part}(a_{l+1}) = a_l$ but a_{l+1} is not on the path between u_i and u_{i+1}, then there must be a leaf x in the subtree of a_{l+1} which implies $u_i <_{\text{par}} x <_{\text{par}} u_{i+1}$, and thus leads to a contradiction. If $\text{part}(a_l) = a_{l+1}$ but a_{l+1} is not on the path between u_i and u_{i+1}, then both u_i and u_{i+1} should be in the subtree of a_l, and both of u_i and u_{i+1} should be in the DFS sequence of the subtree of a_l. But we know a_{l+1} cannot be in the DFS sequence of the subtree of a_l. This leads to a contradiction. □

Lemma 32.6.7. *Let* $\text{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*, with a unique root. Let* $v \in V$*. Let* $V' = V \backslash \{u \in V \mid v$ *is an ancestor (See Definition 32.6.1) of* u*. Let* $\text{par}' : V' \to V'$ *satisfy* $\forall u \in V', \text{par}'(u) = \text{part}(u)$*. Then the DFS sequence (See Definition 32.6.7) of* par′ *is a subsequence of the DFS sequence of* par*.*

Proof. The proof follows by the property 3 of Fact 32.6.4 directly. □

Corollary 32.6.8. *Let* $\text{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*, and* par *has a unique root. Let* $v_1, v_2, \cdots, v_t$ *be* t *vertices in* V*. Let* $V' = V \backslash \{u \in V \mid \exists v \in \{v_1, \cdots, v_t\}, v$ *is an ancestor (See Definition 32.6.1) of* $u\}$*. Let* $\text{par}' : V' \to V'$ *satisfy* $\forall u \in V', \text{par}'(u) = \text{part}(u)$*. Then the DFS sequence (See Definition 32.6.7) of* par′ *is a subsequence of the DFS sequence of* par*.*

Proof. The proof is by induction on t. When $t = 1$, then the statement is true by Lemma 32.6.7. Suppose the statement is true for $t-1$. Let $V'' = V \backslash \{u \in V \mid \exists v \in \{v_1, \cdots, v_{t-1}\}, v$ is an ancestor of $u\}$, and let $\text{par}'' : V'' \to V''$ satisfy $\forall v \in V'', \text{par}''(v) = \text{part}(v)$. By induction hypothesis, the DFS sequence of par″ is a subsequence of the DFS sequence of par. If one of the $v_1, \cdots, v_{t-1}$ is an ancestor of v_t, then par′ = par″, thus, the DFS sequence of par′ is a subsequence of

the DFS sequence of par. Otherwise, we have $V' = V'' \setminus \{u \in V'' \mid v_t \text{ is an ancestor of } u\}$. By Lemma 32.6.7, the DFS sequence of par$'$ is a subsequence of the DFS sequence of par$''$. Thus, the DFS sequence of par$'$ is a subsequence of the DFS sequence of par. □

Lemma 32.6.9 (Removing several subtrees)**.** *Let* par $: V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*, and* par *has a unique root. Let* $m > 0, \delta \in (0, 1)$ *be parameters, and let* $|V| \leq m^{1/\delta}$*. Let* $(V', A) = \textsc{SubDFS}(\text{par}, m, \delta)$ *(Algorithm 32.16). Then* $\forall u \in V'$*, we have* $\text{part}(u) \in V'$*. Furthermore, with probability at least* $1 - 1/(100m^{5/\delta})$*,* $\forall u \in V \setminus V'$*, the number of leaves (See Definition 32.6.5) in the subtree (See Definition 32.6.6) of* u *is at most* $\lfloor |\text{leaves}(\text{par})|/\lceil m^{1/3} \rceil \rfloor$.

Proof. By Lemma 32.6.5, we know $L \subseteq \text{leaves}(\text{par})$, and $l_1 <_{\text{par}} l_2 <_{\text{par}} \cdots <_{\text{par}} l_t$.

We first prove $\forall u \in V', \text{part}(u) \in V'$. Our proof is by induction on the leaf l_i. By Lemma 32.6.1, we have that $\forall i \in [t-1], p_{l_i,l_{i+1}}$ is the LCA of (l_i, l_{i+1}), $p_{i,l_{i+1}}$ is an ancestor of l_{i+1}, and $p_{i,l_{i+1}} \neq p_{l_i,l_{i+1}}, \text{part}(p_{i,l_{i+1}}) = p_{l_i,l_{i+1}}$. By Lemma 32.14, P_1 contains all the vertices on the path from l_1 to the root v. P_1 is the set of all the ancestors of l_1. Thus, every ancestor u of l_1 is in P_1 and satisfies $\text{part}(u) \in V'$. P_2 contains all the vertices on the path from l_1 to an ancestor of l_1. Thus, $P_2 \subseteq P_1$. Suppose now $P_1 \cup P_2 \cup \cdots \cup P_{2i-2} = \{u \in V \mid \exists j \in [i-1], u \text{ is an ancestor of } l_j\}$. Notice that P_{2i-1} contains all the vertices on the path from l_i to the ancestor p_{i-1,l_i}. Since $\text{part}(p_{i-1,l_i}) = p_{l_{i-1},l_i}$ is also an ancestor of l_{i-1}, we have $P_1 \cup P_2 \cup \cdots \cup P_{2i-2} \cup P_{2i-1} = \{u \in V \mid \exists j \in [i], u \text{ is an ancestor of } l_j\}$. Since P_{2i} contains all the vertices on the path from l_i to an ancestor of l_i, we have $P_{2i} \subseteq P_1 \cup P_2 \cup \cdots \cup P_{2i-2} \cup P_{2i-1}$. To conclude, we have $V' = P_1 \cup P_2 \cup \cdots \cup P_{2t} = \{u \in V \mid \exists j \in [t], u \text{ is an ancestor of } l_j\}$. Thus, $\forall u \in V'$, we have $\text{part}(u) \in V'$.

By Lemma 32.6.5, with probability at least $1 - 1/(100m^{5/\delta})$, $\forall u \in \text{leaves}(\text{par}) \setminus L$, there exists $w \in L, w <_{\text{par}} u$ such that $|\{x \in \text{leaves}(\text{par}) \mid w <_{\text{par}} x <_{\text{par}} u\}| \leq \lfloor |\text{leaves}(\text{par})|/\lceil m^{1/3} \rceil \rfloor$. In the following, we condition on the above event happens. Let $u \in V \setminus V'$. Due to Fact 32.6.4, the DFS sequence of the subtree of u in par must be a consecutive subsequence of the DFS sequence of par. Thus, $\exists x, y \in \text{leaves}(\text{par})$, the leaves in the subtree of u in par is the set $\{z \in \text{leaves}(\text{par}) \mid x <_{\text{par}} z <_{\text{par}} y\} \cup \{x\} \cup \{y\}$. If the number of leaves in the subtree of u is more than $\lfloor |\text{leaves}(\text{par})|/\lceil m^{1/3} \rceil \rfloor$, then $\exists l_i \in L$, u is an ancestor of leaf l_i. But $l_i \in V'$ contradicts to $u \notin V'$. Thus, the number of leaves in the subtree of u is at most $\lfloor |\text{leaves}(\text{par})|/\lceil m^{1/3} \rceil \rfloor$. □

Lemma 32.6.10 (A is a subsequence)**.** *Let* $\text{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*, and* par *has a unique root. Let* $m > 0, \delta \in (0, 1)$ *be parameters, and let* $|V| \leq m^{1/\delta}$*. Let* $(V', A) = \textsc{SubDFS}(\text{par}, m, \delta)$ *(Algorithm 32.16). Then* A *is a subsequence of the DFS sequence of* par*. Furthermore,* $\forall u \in V'$*,* u *appears in* A *exactly* $|\text{child}_{\text{par}}(u) + 1|$ *times, and* $\forall u \notin V'$*,* u *does not appear in* A*.*

Proof. We first show that A' is the DFS sequence of par'.

Claim 32.6.11. A' *is the DFS sequence of* $\text{par}' : V' \to V'$*.*

Proof. By Lemma 32.6.5, we know $\{l_1, l_2, \cdots, l_t\} = L \subseteq \text{leaves}(\text{par})$, and $l_1 <_{\text{par}} l_2 <_{\text{par}} \cdots <_{\text{par}} l_t$. By Lemma 32.6.1, we have that $\forall i \in [t-1], p_{l_i,l_{i+1}}$ is the LCA of (l_i, l_{i+1}), $p_{i,l_{i+1}}$ is an ancestor of l_{i+1}, and $p_{i,l_{i+1}} \neq p_{l_i,l_{i+1}}, \text{part}(p_{i,l_{i+1}}) = p_{l_i,l_{i+1}}$. By Lemma 32.14, $\forall i \in [t]$, P_{2i-1} and P_{2i} only contains some ancestors of l_i. Thus, $\text{leaves}(\text{par}') = L$.

According to Lemma 32.6.9 and Corollary 32.6.8, the DFS sequence of par' is a subsequence of the DFS sequence of par. Thus, we still have $l_1 <_{\text{par}'} l_2 <_{\text{par}'} <_{\text{par}'} \cdots <_{\text{par}'} l_t$.

Due to Lemma 32.14, P_1 contains all the vertices on the path from l_1 to the root v, P_{2t} contains all the vertices on the path from l_t to the root v, $\forall i \in [t-1], P_{2i}$ contains all the vertices on the path from $\text{par}'(l_i)$ to the LCA of (l_i, l_{i+1}), and P_{2i+1} contains all the vertices on the path from l_{i+1} to $p_{i,l_{i+1}}$. Thus, A'_1 is the path from the root v to leaf l_1, A'_{2t} is the path from l_t to the root v, $\forall i \in [t-1]$, $A'_{2i}A'_{2i+1}$ is the path from $\text{par}'(l_i)$ to l_{i+1}. Due to Fact 32.6.6, $A' = A'_1A'_2 \cdots A'_{2t}$ is the DFS sequence of par'. □

Let us define some notations. Let $\widetilde{A} = \{\widetilde{a}_1, \widetilde{a}_2, \cdots, \widetilde{a}_{\widetilde{s}}\}$ be the DFS sequence of par. $\forall u \in V$, let $\text{st}_{\widetilde{A}}(u) = j$ such that $\widetilde{a}_j$ is the first time that u appears in $\widetilde{A}$. We define $\text{ed}_{\widetilde{A}}(u)$ be the position such that $\widetilde{a}_{\text{ed}_{\widetilde{A}}(u)}$ is the last time that u appears in $\widetilde{A}$. Similarly, $\forall u \in V'$, we can define $\text{st}_{A'}(u), \text{st}_A(u), \text{ed}_{A'}(u), \text{ed}_A(u)$ to be the positions of the first time u appears in A', the first time u appears in A, the last time u appears in A', and the last time u appears in A respectively.

Since v is the root (in both par and par'), it suffices to prove that $(a_{\text{st}_A(v)}, a_{\text{st}_A(v)+1}, \cdots, a_{\text{ed}_A(v)})$ is a subsequence of $(\widetilde{a}_{\text{st}_{\widetilde{A}}(v)}, \widetilde{a}_{\text{st}_{\widetilde{A}}(v)+1}, \cdots, \widetilde{a}_{\text{ed}_{\widetilde{A}}(v)})$. Our proof is by induction on $\text{dep}_{\text{par}}(u)$ for $u \in V'$. If $\text{dep}_{\text{par}}(u) = \text{dep}(\text{par})$, then u must be a leaf in par' (or par, since par' and par are the same on V'). In this case, $\text{st}_A(u) = \text{ed}_A(u), \text{st}_{\widetilde{A}}(u) = \text{ed}_{\widetilde{A}}(u)$, and $(a_{\text{st}_A(u)}) = (\widetilde{a}_{\text{st}_{\widetilde{A}}(u)}) = (u)$. Suppose for all $u \in V'$ with $\text{dep}_{\text{par}}(u) > d$, we have that $(a_{\text{st}_A(u)}, \cdots, a_{\text{ed}_A(u)})$ is a subsequence of $(\widetilde{a}_{\text{st}_{\widetilde{A}}(u)}, \cdots, \widetilde{a}_{\text{ed}_{\widetilde{A}}(u)})$. Let u be a vertex in V' with $\text{dep}_{\text{par}}(u) = d$. If u is a leaf, then it is the same as the previous argument. Now let us consider the case when u is not a leaf. According to Claim 32.6.11, A' is the DFS sequence of par'. Due to line 30, A is obtained by duplicating each element of A' several times. Let $w_1, w_2, \cdots, w_k$ be the children of u in par', and $\text{rank}_{\text{par}'}(w_1) = 1, \text{rank}_{\text{par}'}(w_2) = 2, \cdots, \text{rank}_{\text{par}'}(w_k) = |\text{child}_{\text{par}'}(u)|$. Then, according to

Fact 32.6.4, $(a_{\mathrm{st}_A(u)}, \cdots, a_{\mathrm{ed}_A(u)})$ should look like:

$$(u, \cdots, u, a_{\mathrm{st}_A(w_1)}, \cdots, a_{\mathrm{ed}_A(w_1)}, u, \cdots, u, a_{\mathrm{st}_A(w_2)}, \cdots, a_{\mathrm{ed}_A(w_2)}, \cdots, a_{\mathrm{st}_A(w_k)}, \cdots, a_{\mathrm{ed}_A(w_k)}, u, \cdots, u)$$

where the number of u before $a_{\mathrm{st}_A(w_1)}$ is $\mathrm{rank}_{\mathrm{par}}(w_1)$ (see line 26), the number of u before $a_{\mathrm{st}_A(w_i)}$ for $i \in [k] \setminus \{1\}$ is $\mathrm{rank}_{\mathrm{par}}(w_i) - \mathrm{rank}_{\mathrm{par}}(w_{i-1})$ (see line 28), and the number of u after $a_{\mathrm{ed}_A(w_k)}$ is $|\operatorname{child}_{\mathrm{par}}(u)| - \mathrm{rank}_{\mathrm{par}}(w_k) + 1$ (see line 27). Since $\widetilde{A}$ is the DFS sequence of par, according to Fact 32.6.4, the number of u in $\widetilde{A}$ before $\widetilde{a}_{\mathrm{st}_{\widetilde{A}}(w_1)}$ is $\mathrm{rank}_{\mathrm{par}}(w_1)$. By our induction hypothesis, $(a_{\mathrm{st}_A(w_1)}, \cdots, a_{\mathrm{ed}_A(w_1)})$ is a subsequence of $(\widetilde{a}_{\mathrm{st}_{\widetilde{A}}(w_1)}, \cdots, \widetilde{a}_{\mathrm{ed}_{\widetilde{A}}(w_1)})$. Thus, $(a_{\mathrm{st}_A(u)}, \cdots, a_{\mathrm{ed}_A(w_1)})$ is a subsequence of $(\widetilde{a}_{\mathrm{st}_{\widetilde{A}}(u)}, \cdots, \widetilde{a}_{\mathrm{ed}_{\widetilde{A}(w_1)}})$. According to Fact 32.6.4, $\forall i \in [k] \setminus \{1\}$, the number of u in $\widetilde{A}$ between $\widetilde{a}_{\mathrm{ed}_{\widetilde{A}}(w_{i-1})}$ and $\widetilde{a}_{\mathrm{st}_{\widetilde{A}}(w_i)}$ is $\mathrm{rank}_{\mathrm{par}}(w_i) - \mathrm{rank}_{\mathrm{par}}(w_{i-1})$. By our induction hypothesis, for all $i \in [k] \setminus \{1\}$, $(a_{\mathrm{st}_A(w_i)}, \cdots, a_{\mathrm{ed}_A(w_i)})$ is a subsequence of $(\widetilde{a}_{\mathrm{st}_{\widetilde{A}}(w_i)}, \cdots, \widetilde{a}_{\mathrm{ed}_{\widetilde{A}}(w_i)})$. Thus, $(a_{\mathrm{st}_A(u)}, \cdots, a_{\mathrm{ed}_A(w_k)})$ is a subsequence of $(\widetilde{a}_{\mathrm{st}_{\widetilde{A}}(u)}, \cdots, \widetilde{a}_{\mathrm{ed}_{\widetilde{A}(w_k)}})$. According to Fact 32.6.4, the number of u in $\widetilde{A}$ after $\widetilde{a}_{\mathrm{ed}_{\widetilde{A}}(w_k)}$ is $|\operatorname{child}_{\mathrm{par}}(u)| - \mathrm{rank}_{\mathrm{par}}(w_k) + 1$. Thus, $(a_{\mathrm{st}_A(u)}, \cdots, a_{\mathrm{ed}_A(u)})$ is a subsequence of $(\widetilde{a}_{\mathrm{st}_{\widetilde{A}}(u)}, \cdots, \widetilde{a}_{\mathrm{ed}_{\widetilde{A}(u)}})$. Furthermore, the number of u appears in A is $|\operatorname{child}_{\mathrm{par}}(u)| - \mathrm{rank}_{\mathrm{par}}(w_k) + 1 + \mathrm{rank}_{\mathrm{par}}(w_1) + \sum_{i=2}^{k} \mathrm{rank}_{\mathrm{par}}(w_i) - \mathrm{rank}_{\mathrm{par}}(w_{i-1}) = |\operatorname{child}_{\mathrm{par}}(u)| + 1$.

Since A' is the DFS sequence of par', $\forall u \notin V'$, u does not appear in A'. Thus, $\forall u \notin V'$, u does not appear in A.

□

32.6.2.3 DFS Sequence

In this section, we show how to use Algorithm 32.16 as a subroutine to output a DFS sequence. The high level idea is that we use Algorithm 32.16 to generate subsequences of

the DFS sequence in each iteration, and we ensure that the miss part of the DFS sequence must be the DFS sequences of many subtrees. After the i^{th} iteration, we should ensure that the number of leaves of each subtree which has missing DFS sequence is at most n/m^i, where m is some parameter depends on some computational resources (e.g. memory size of a machine). The description of the algorithm is shown in Algorithm 32.17. Figure 32.2 shows one step in our algorithm.

Theorem 32.6.12 (Correctness of DFS sequence)**.** *Let* par $: V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*, and* par *has a unique root. Let* $n = |V|, m = n^\delta$ *for some constant* $\delta \in (0, 1)$*. If* $A = \mathrm{DFS}(\mathrm{par}, m)$ *(Algorithm 32.17) does not output* FAIL*, then* A *is the DFS sequence of* par *.*

Proof. It suffices to prove the following claim.

Claim 32.6.13. *Let* $i \in \{0\} \cup [r]$*.* A_i *is a subsequence of the DFS sequence of* par *.* $\forall v \in V_i$, $\mathrm{part}(v) \in V_i$*. Furthermore,* $\forall v \in V_i$*,* v *appears in* A_i *exactly* $|\mathrm{child}_{\mathrm{par}}(v)| + 1$ *times, and* $\forall v \notin V_i$*,* v *does not appear in* A_i*.*

Proof. Our proof is by induction on i. If $i = 0$, then by Lemma 32.6.10, A_0 is a subsequence of the DFS sequence of par, $\forall v \in V_0$, v appears in A_0 exactly $|\mathrm{child}_{\mathrm{par}}(v)| + 1$ times, and $\forall v \notin V_0$, v does not appear in A_0. By Lemma 32.6.9, we have $\forall v \in V_0, \mathrm{part}(v) \in V_0$.

Suppose the claim is true for $i - 1$. Let $u \in V_i$.

If $u \in V_{i-1}$, then since $V_{i-1} \subseteq V_i$, $\mathrm{part}(u) \in V_i$. Otherwise $u \in V_{i,v}$ for some v with $\mathrm{par}_i(v) = v$. If $u = v$, then $\mathrm{part}(v) \in V_{i-1} \subseteq V_i$. Otherwise, by Lemma 32.6.9, $\mathrm{part}(u) \in V_{i,v} \subseteq V_i$.

Now consider the property of A_i. If $u \in V_{i-1}$, then since A_{i-1} is a subsequence of A_i, and by Lemma 32.6.10 u cannot appear in any $A_{i,v}$, u must appear in A_i exactly $|\operatorname{child}_{\text{par}}(u)| + 1$ times. Otherwise $u \in V_{i,v}$ for some v with $\text{par}_i(v) = v$. By Lemma 32.6.10, u must appear in $A_{i,v}$ $|\operatorname{child}_{\text{par}_{i,v}}(u)| + 1 = |\operatorname{child}_{\text{par}}(u)| + 1$ times. Since u cannot appear in A_{i-1}, u must appear in A_i exactly $|\operatorname{child}_{\text{par}}(u)| + 1$ times. For $v \in V_i'$ with $\text{par}_i(v) = v$, according to Fact 32.6.4 and $\forall w \in \{x \in V \mid v \text{ is an ancestor of } x\}$, w cannot be in V_{i-1}, the $\text{rank}_{\text{par}}(v)^{\text{th}}$ time appearance of v and the $(\text{rank}_{\text{par}}(v)+1)^{\text{th}}$ time appearance of v should be adjacent in A_{i-1}. Due to Lemma 32.6.10, $A_{i,v}$ is a subsequence of the DFS sequence of the subtree of v in par . Due to Fact 32.6.4, A_i is still a subsequence of the DFS sequence of par after insertion of the sequence $A_{i,v}$.

For any $x \notin V_i$, by Lemma 32.6.10, x cannot be in any $A_{i,v}$. By our induction hypothesis, x cannot be in A_{i-1}. Thus, x cannot be in A_i. □

If the procedure does not output FAIL, then according to the above Claim 32.6.13, $\forall v \in V_r = V$, v appears in $A_r = A$ exactly $|\operatorname{child}_{\text{par}}(v)|+1$ times, and $A_r = A$ is a subsequence of the DFS sequence of par. Due to Fact 32.6.4, $A = A_r$ is the DFS sequence of par. □

The following lemma claims the success probability of Algorithm 32.17.

Theorem 32.6.14 (Success probability)**.** *Let* $\text{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*, and* par *has a unique root. Let* $n = |V|, m = n^{\delta}$ *for some constant* $\delta \in (0, 1)$*. With probability at least* $1 - 1/(100n^4)$*,* $A = \text{DFS}(\text{par}, m)$ *(Algorithm 32.17) does not output* FAIL*.*

Proof. $\forall i \in [r], v \in V'_i$ with $\mathrm{par}_i(v) = v$, let $\mathcal{E}_{i,v}$ be the event that $\forall u \in V'_i(v) \setminus V_{i,v}$, the number of leaves in the subtree of u in par is at most $|\operatorname{leaves}(\mathrm{par}_{i,v})|/n^{\delta/3}$. Notice that due to Lemma 32.6.9, if $\mathrm{par}_i(v) = v$, then v will be in V_i. Thus, we use $\mathcal{E}_v$ to denote the event $\mathcal{E}_{i,v}$. By Lemma 32.6.9, $\mathcal{E}_v$ happens with probability at least $1 - 1/(100n^5)$. By taking union bound over all v, with probability at least $1 - 1/(100n^4)$, all the events $\mathcal{E}_v$ will happen.

Claim 32.6.15. *Condition on all the events $\mathcal{E}_v$ happen. $\forall i \in [r], v \in V'_i$ with $\mathrm{par}_i(v) = v$, we have $|\operatorname{leaves}(\mathrm{par}_{i,v})| \le n/n^{(i-1)\delta/3}$.*

Proof. When $i = 1$, the claim is obviously true, since $|\operatorname{leaves}(\mathrm{par}_{i,v})| \le n$. Suppose the claim holds for $i - 1$. Let $v \in V'_i$ with $\mathrm{par}_i(v) = v$. There must be $v' \in V'_{i-1}$ with $\mathrm{par}_{i-1}(v') = v'$, and $v \in V'_{i-1}(v') \setminus V_{i-1,v'}$. Since $\mathcal{E}_{v'}$ happens, the number of leaves in the subtree of v in par is at most $|\operatorname{leaves}(\mathrm{par}_{i-1,v'})|/n^{\delta/3} \le n/n^{(i-1)\delta/3}$. □

If $V'_r \neq \emptyset$, then $\exists v \in V'_r$ with $\mathrm{par}_i(v) = v$ and $|\operatorname{leaves}(\mathrm{par}_{i,v})| \ge 1$. If all the events $\mathcal{E}_v$ happens, it will contradict to Claim 32.6.15. Thus, if all the events $\mathcal{E}_v$ happens, V'_r must be $\emptyset$, and thus $V_r = V$ which implies that the procedure will not fail. □

32.6.3 Range Minimum Query

Range Minimum Query (RMQ) problem is defined as following: given a sequence of n numbers $a_1, a_2, \cdots, a_n$, the goal is to preprocess the sequence a to get a data structure such that for any query $(p, q), (p < q)$ we can efficiently find the element which is the minimum in $a_p, a_{p+1}, \cdots, a_q$. A classic method is to preprocess a sparse table f in $\log(n)$ number of iterations such that $\forall i \in [n], j \in [\lceil \log n \rceil] \cup \{0\}$, $f_{i,j} = \arg\min_{i \le i' \le \min(n, i+2^j-1)} a_i$. To answer query for (p, q), it just needs to return $\arg\min_{i \in \{f_{p,j^*}, f_{q-2^{j^*}+1,j^*}\}} a_i$ for $j^* = \lfloor \log(q - p + 1) \rfloor$. In this section, we firstly show a modified data structure. We will compute $\widehat{f}_{i,j} = \arg\min_{i \le i' \le \min(n, i+\lceil n^\delta \rceil^j - 1)} a_{i'}$ The Algorithm is shown in Algorithm 32.18. Then we show how to use $\widehat{f}$ to compute f in Algorithm 32.19.

Lemma 32.6.16. *Let $a_1, a_2, \cdots, a_n$ be a sequence of numbers, and $\delta \in (0, 1)$. Let $\{\widehat{f}_{p,q}\}$ be the output of* SparseTable$^+(a_1, a_2, \cdots, a_n, \delta)$ *(Algorithm 32.18). Then $\forall p \in [n], q \in \{0\} \cup [\lceil 1/\delta \rceil]$, $\widehat{f}_{p,q} = \arg\min_{p \le p' \le \min(n, i+\lceil n^\delta \rceil^q - 1)} a_{p'}$.*

Proof. The proof is by induction on q. When $q = 0$, the statement obviously holds for all $\widehat{f}_{p,0}$. Suppose all $p \in [n], \widehat{f}_{p,0}, \widehat{f}_{p,1}, \cdots, \widehat{f}_{p,q-1}$ satisfy the property. The first observation is that the value of $\widehat{f}_{p,q}$ will be assigned in the procedure when $l = q, j = \lfloor (p - 1)/m \rfloor, i' = (p - 1) \mod m$. Then by line 8, $z^*_{j,l}$ will be the position of the minimum value in $a_{j \cdot m+m}, a_{j \cdot m+m+2}, \cdots, a_{j \cdot m+m^l-1}$ by our induction hypothesis. Then by line 11, $\widehat{f}_{i+i',l}$ will be the position of the minimum value in $a_{j \cdot m+i'+1}, a_{j \cdot m+i'+2}, \cdots, a_{j \cdot m+i'+m^l}$. Thus, Since $j \cdot m + i' + 1 = p$, $\widehat{f}_{p,q}$ satisfies the property. □

Lemma 32.6.17. *Let $a_1, a_2, \cdots, a_n$ be a sequence of numbers, and $\delta \in (0,1)$. Let $\{f_{p,q}\}$ be the output of* SparseTable$(a_1, a_2, \cdots, a_n, \delta)$ *(Algorithm 32.19). Then $\forall p \in [n], q \in \{0\} \cup [\lceil \log n \rceil]$, $f_{p,q} = \arg\min_{p \le p' \le \min(n, i+2^q-1)} a_{p'}$.*

Proof. Let $m = \lceil n^\delta \rceil$. By Lemma 32.6.16, $\forall x \in [n], y \in \{0\} \cup [\lceil 1/\delta \rceil]$, $\widehat{f}_{x,y} = \arg\min_{x \le x' \le \min(n, i+m^y-1)} a_{x'}$. Thus, by the definition of S_t, we know $z^*_{j,t} = \arg\min_{j \cdot m + m + 1 \le z \le j \cdot m + 2^t} a_z$. An observation is that the value of $f_{p,q}$ will be assigned in the procedure when $t = q, j = \lfloor (p-1)/m \rfloor, i' = (p-1) \bmod m$. By line 23, we know

$$f_{p,q} = f_{i+i',t} = \arg \min_{z: i+i'+1 \le z \le i+i'+2^t} a_z = \arg \min_{p \le p' \le \min(n, i+2^q-1)} a_{p'}.$$

□

32.6.4 Applications of DFS Sequence

In this section, we briefly discuss some applications of the DFS sequence of a tree.

Since the DFS sequence of a subtree should be a continuous subsequence of the DFS sequence of the tree, one direct application of the DFS sequence is to compute the size of each subtree, i.e. for each subtree with root v, we can find the first place v appeared and the last place v appeared, and then calculate the vertices between those two appearances.

Another application of the DFS sequence and the range minimum query is to output a data structure which can answer any LCA query in $O(1)$ time (for both sequential and parallel). This is better than the data structure provided by Section 32.6.1 which needs $O(\log D)$ time (for both sequential and parallel) to answer the query.

Since it is easy to output a data structure which can answer the depth of each vertex in $O(1)$ time (in both sequential and parallel), together with the lowest common ancestor data structure, we can answer the query of the tree distance between any two vertices in $O(1)$ time (for both sequential and parallel).

32.7 The MPC Model

In this section, let us introduce the computational model studied in this paper. Suppose we have p machines indexed from 1 to p each with memory size s words, where n is the number of words of the input and $p \cdot s = O(n^{1+\gamma}), s = \Theta(n^{\delta})$. Here $\delta \in (0, 1)$ is a constant, $\gamma \in \mathbb{R}_{\geq 0}$, and a word has $\Theta(\log(s \cdot p))$ bits. Thus, the total space in the system is only $O(n^{\gamma})$ factor more than the input size n, and each machine has local memory size sublinear in n. When $0 \leq \gamma \leq O(1/\log n)$, the total space is just linear in the input size. The computation proceeds in rounds. At the beginning of the computation, the input is distributed on the local memory of $\Theta(n/s)$ input machines. Input machines and other machines are identical except that input machine can hold a part of the input in its local memory at the beginning of the computation while each of other machines initially holds nothing. In each round, each machine performs computation on the data in its local memory, and sends messages to other machines (including the sender itself when it wants to keep the data) at the end of the round. Although any two machines can communicate directly in any round, the total size of messages (including the self-sent messages) sent or received of a machine in a round is bounded by s, its local memory size. In the next round, each machine only holds the received messages in its local memory. At the end of the computation, the output is distributed on the output machines. Output machines and other machines are identical except that output machine can hold a part of the output in its local memory at the end of the computation while each of other machines holds nothing. We call the above model $(\gamma, \delta) - \text{MPC}$ model. The model is exactly the same as the model MPC(ϵ) defined by [BKS13] with $\epsilon = \gamma/(1 + \gamma - \delta)$ and the number of machines $p = O(n^{1+\gamma-\delta})$. Since we care more about the total space used by the algorithm, we use (γ, δ) to characterize the model, while in [BKS13] they use parameter

ϵ to characterize the repetition of the data. The main complexity measure is the number of rounds R required to solve the problem.

32.7.1 Basic MPC Algorithms

Sorting One of the most important algorithms in MPC model is sorting. The following theorem shows that there is an efficient sorting algorithm.

Theorem 32.7.1 ([GSZ11, Goo99]). *Sorting can be solved in c/δ rounds in $(0,\delta)-$MPC model for any constant $\delta \in (0,1)$, where $c \geq 0$ is a universal constant. Precisely, there is an algorithm $\mathcal{A}$ in $(0,\delta)-$MPC model such that for any set S of n comparable items stored $O(n^\delta)$ per machine on input machines, $\mathcal{A}$ can run in c/δ rounds and leave the n items sorted on the output machines, i.e. the ouput machine with smaller index holds a smaller part of $O(n^\delta)$ items.*

Notice that for any $\delta' \geq \delta$, $O(1)$ number of machines with $\Theta(n^{\delta'})$ memory can always simulate the computation of $O(n^{\delta'-\delta})$ number of machines with $\Theta(n^\delta)$ memory. Thus, if an algorithm $\mathcal{A}$ can solve a problem in $(\gamma,\delta)-$MPC model in $R(n)$ rounds, then $\mathcal{A}$ can be simulated in $(\gamma',\delta')-$MPC model still in $R(n)$ rounds with all $\gamma' \geq \gamma, \delta' \geq \delta$.

Indexing In the indexing problem, a set $S = \{x_1, x_2, \cdots, x_n\}$ of n items are stored $O(n^\delta)$ per machine on input machines. The output is

$$S' = \{(x,y) \mid x \in S, y-1 \text{ is the number of items before } x\}$$

of n pairs stored $O(n^\delta)$ per machine on output machines. Here, "an item $x' \in S$ is before $x \in S$" means that x' is held by a input machine with a smaller index, or x', x are stored in the same input machine but x' has a smaller local memory address.

Prefix sum In the prefix sum problem, a set $S = \{(x_1, y_1), (x_2, y_2), \cdots, (x_n, y_n)\}$ of n (item, number) pairs are stored $O(n^\delta)$ per machine on input machines. The output is

$$S' = \left\{ (x, y') \;\middle|\; (x, y) \in S, y' - y = \sum_{(\widetilde{x},\widetilde{y}) \text{ is before } (x,y)} \widetilde{y} \right\}$$

of n pairs stored $O(n^\delta)$ per machine on output machines. Here, "an pair $(\widetilde{x}, \widetilde{y}) \in S$ is before $(x, y) \in S$" means that $(\widetilde{x}, \widetilde{y})$ is held by a input machine with a smaller index, or $(\widetilde{x}, \widetilde{y}), (x, y)$ are stored in the same input machine but $(\widetilde{x}, \widetilde{y})$ has a smaller local memory address. Notice that indexing problem is a special case of prefix sum problem.

Theorem 32.7.2 ([GSZ11]). *Indexing/prefix sum problem can be solved in c/δ rounds in $(0, \delta) - \text{MPC}$ model for any constant $\delta \in (0, 1)$, where $c \geq 0$ is a universal constant.*

Once each item has an index, it is able to reallocate them onto the machines.

Load balance Sometimes, local computations of a machine may generate new data. When some machines are not able to keep the new data generated, we need to do loading balance. Fortunately, this operation can be done in constant number of rounds of computations.

For arbitrary constant $\delta \in (0, 1)$, we are able to spend constant number of rounds to reallocate the data in $(0, \delta) - \text{MPC}$ model such that if a machine is not empty, the size of its local data is at least n^δ/k and is at most $2n^\delta/k$ where $k > 1$ is an arbitrary constant. The method is very simple, we can use the algorithm mentioned in Theorem 32.7.2 to index each data item, and then send them to the corresponding machine.

Predecessor In the predecessor problem, a set $S = \{(x_1, y_1), (x_2, y_2), \cdots, (x_n, y_n)\}$ of n (item, 0/1) pairs are stored $O(n^\delta)$ per machine on input machines. The output machines are all input machines. If an input (also output) machine holds a tuple $(x_i, y_i) \in S$ at the beginning of the computation, then at the end of the computation, that machine should still hold the tuple (x_i, y_i). In addition, if an input (also output) machine holds a tuple $(x, 0) \in S$ at the beginning of the computation, then at the end of the computation, that machine should hold a tuple (x, x') such that $(x', 1) \in S$, and $(x', 1)$ is the last tuple occurred before $(x, 0)$. Here, "$(x', 1)$ is before $(x, 0)$" means that $(x', 1)$ is held by a input machine with a smaller index, or $(x', 1), (x, 0)$ are stored in the same input machine but $(x', 1)$ has a smaller local memory address.

Theorem 32.7.3 ([GSZ11])**.** *Predecessor problem can be solved in c/δ rounds in $(0, \delta)-$*MPC *model for any constant $\delta \in (0, 1)$, where $c \geq 0$ is a universal constant.*

Roughly speaking the algorithm is as the following: firstly, build a $\Theta(n^\delta)$ branching tree on the machines, then follows by bottom-up stages to collect the last $(x_l, 1)$ tuple in each large interval and then follows by top-down stages to compute the predecessors of every prefix. For completeness, we describe the algorithm for predecessor problem in the following:

Predecessor Algorithm:

- **Setups:**
  - There are $2p = \Theta(n^\delta)$ machines indexed from 1 to $2p$ each with local memory size $s = \Theta(n^\delta)$. The machine with index from $p+1$ to $2p$ are input/output machines.
  - $(x_1, y_1), \cdots (x_n, y_n)$ are stored on input/output machine $p+1$ to $2p$, where $\forall i \in [n], y_i \in \{0, 1\}$.
  - The goal: If an input machine holds a tuple (x, y) with $y = 0$, then it will create a tuple (x, x') at the end of the computation, where (x', y') is the last tuple with $y' = 1$ stored before (x, y).
- **Bottom-up stage ($O(1/\delta)$ constant rounds):**
  - Let $d = s/10$ be the branching factor.
  - In the i^{th} round, each machine j with j in the range $\lfloor p/d^{i-1} \rfloor + 1$ to $\lfloor (2p-1)/d^{i-1} \rfloor + 1$ sends the last (x_l, y_l) tuple with $y_l = 1$ in its local memory to machine $\lfloor (j-1)/d \rfloor + 1$. If machine j does not have any tuple with $y_l = 1$, it just sends an arbitrary tuple to machine $\lfloor (j-1)/d \rfloor + 1$.
  - Until the end of the computation, machine j sends itself messages to keep the data. The stage ends when machine 1 receives messages.
- **Top-down stage ($O(1/\delta)$ constant rounds):**
  - Let $d = s/10$ be the branching factor.
  - In the i^{th} round, each machine j with j in the range $\lfloor d^{i-2} \rfloor + 1$ to $\min(d^{i-1}, p)$ sends to each machine h in the range $(j-1)d+1$ to $\min(j \cdot d, 2p)$ a tuple (x_l, y_l) which is the last tuple with $y_l = 1$ appeared before machine h.
  - The stage ends when machine $2p$ receives messages.
- **The last round:**
  - Machine $i \in \{p+1, \cdots, 2p\}$ scans its local memory, for each tuple (x, y) with $y = 0$, create a tuple (x, x') where (x', y') is the last tuple stored before (x, y) with $y' = 1$.

32.7.2 Data Organization

In this section, we introduce the method to organize the data in the system.

Set Let $S = \{x_1, x_2, \cdots, x_m\}$ be a set of m items, and each item x_i can be described by $O(1)$ number of words. If $x \in S$ is equivalent to that there is a unique machine which holds a pair ("S", x) in its local memory, then we say that S is stored in the system. Here "S" is the name of the set S and can be described by $O(1)$ number of words.

Let $\mathcal{S} = \{S_1, S_2, \cdots, S_m\}$ be a set of m sets, where $\forall i \in [m]$, S_i is stored in the system, and the name "S_i" of each set S_i can be described by $O(1)$ number of words. If $S \in \mathcal{S}$ is equivalent to that there is a unique machine which holds a pair ("$\mathcal{S}$", "S") in its local memory, then we say $\mathcal{S}$ is stored in the system. Here "$\mathcal{S}$" is the name of $\mathcal{S}$ and can be described by $O(1)$ number of words.

Let S be a set stored in the system. If machine i has a pair ("S", x), then we say that the element x of S is held by the machine i. If every element of S is held by a machine with index in $\{i, i+1, \cdots, j\}$, then we say S is stored on the machine i to the machine j.

The total space needed to store S is $\Theta(m)$.

Mapping Let $f : U \to H$ be a mapping from a finite set U to a set H. In the following, we show how to use a set to represent a mapping.

Definition 32.7.1 (Set representation of a mapping)**.** Let $f : U \to H$ be a mapping from a finite set U to a set H. Let $S = \{(x, y) \mid x \in U, y = f(x)\}$. then the set S is a set representation of the mapping f.

Let U be a finite set where each element of U can be described by $O(1)$ number of words. Let S be a set representation of the mapping $f : U \to H$. If S is stored in the system, then we say f is stored in the system. If S is stored on the machine i to the machine j, then f is stored on the machine i to the machine j. At any time of the system, there can be at most one set representation S of f stored in the system. Furthermore, the name of S is "f" which is the same as the name of mapping f, and can be described by $O(1)$ number of words.

The total space needed to store f is the total space needed to store S, and thus is $\Theta(|U|)$.

Sequence Let $A = (a_1, a_2, \cdots, a_m)$ be a sequence of m elements. In the following, we show how to use a set to represent a sequence.

Definition 32.7.2 (Set representation of a sequence)**.** Let $A = (a_1, a_2, \cdots, a_m)$ be a sequence of n elements. If a set $S = \{(x_1, y_1), (x_2, y_2), \cdots, (x_m, y_m)\} \subseteq \mathbb{R} \times \{a_1, a_2, \cdots, a_m\}$ satisfies $x_1 < x_2 < \cdots < x_m, y_1 = a_1, y_2 = a_2, \cdots, y_m = a_m$, then the set S is a set representation of the sequence A. Furthermore, if $x_1 = 1, x_2 = 2, \cdots, x_m = m$, then S is a standard set representation of A.

Let A be a sequence of elements where each element can be described by $O(1)$ number of words. Let S be a set representation of the sequence A. If S is stored in the system, then we say A is stored in the system. If S is stored on the machine i to the machine j, then A is stored on the machine i to the machine j. At any time of the system, there can be at most one set representation S of A stored in the system. Furthermore, the name of S is

"A" which is the same as the name of sequence A, and can be described by $O(1)$ number of words.

The total space needed to store A is the total space needed to store S, and thus is $\Theta(m)$.

32.7.3 Set Operations

In this section, we introduce some MPC model operations for sets.

Duplicates removing There are n tuples stored in the machines. But there are some duplicates of them. The goal is to remove all the duplicates. To achieve this, we can just sort all the tuples. After sorting, if a tuple is different from its previous tuple, then we keep it. Otherwise, we remove the tuple.

Sizes of sets Suppose we have k sets $S_1, S_2, \cdots, S_k$ stored in the system. Our goal is to get the sizes of all the sets. We can firstly sort all the tuples such that the tuples from the same set are consecutive. Then we can calculate the index of each tuple. Every machine can scan all the tuples in its local memory, if x is an element of set S_i and has the smallest/largest index y, then create a pair ("boundary of 'S_i' ", y). Then we sort all the created pairs, then for each set S_i, there are two pairs ("boundary of 'S_i' ", y_1), ("boundary of 'S_i' ", y_2) stored on the same machine. Each machine can store its local memory. For each pair of tuples ("boundary of 'S_i' ", y_1), ("boundary of 'S_i' ", y_2) with $y_1 < y_2$, the machine can generate a new tuple ("f", ("S_i", $y_2 - y_1 + 1$)). Finally, there will be a mapping f stored in the system, where $f(S_i) = |S_i|$. Thus, the total number of rounds is a constant.

Copies of sets Suppose we have k sets $S_1, S_2, \cdots, S_k$ stored in the system. Let $s_1, s_2, \cdots, s_k \in \mathbb{Z}_{\geq 1}$. If a machine holds an element $x \in S_i$, then the machine knows the value of s_i. Our goal is to create sets $S_{1,1}, S_{1,2}, \cdots, S_{1,s_1}, S_{2,1}, S_{2,2}, \cdots, S_{2,s_2}, \cdots, S_{k,s_k}$ and make them stored in the system, where $S_{i,j}$ is a copy of S_i.

The idea is very simple: for an element $x \in S_i$, we need to make s_i copies $(\text{“}S_{i,1}\text{”}, x), (\text{“}S_{i,2}\text{”}, x), \cdots, (\text{“}S_{i,s_i}\text{”}, x)$ of tuple $(\text{“}S_i\text{”}, x)$. But the issue is that s_i may be very large such that it is not able to generate all the copies of a tuple on a single machine. For the above reason, we implement it in three steps: firstly we compute the new "position" of each original tuple among all the copies, then send the original tuples to their new "positions", and finally filling the gap by generating copies between any two adjacent original tuples. Precisely, each machine can scan its local memory, and assign each tuple $(\text{“}S_i\text{”}, x)$ a weight s_i. Then we can use prefix sum algorithm (See Theorem 32.7.2) to compute the prefix sum of each tuple $(\text{“}S_i\text{”}, x)$. The prefix sum $\text{pos}(\text{“}S_i\text{”}, x)$ of a tuple $(\text{“}S_i\text{”}, x)$ denotes the new "position" of the last copy of this tuple when all the copies are generated. Let $n = \sum_{i=1}^{k} s_i \cdot |S_i|$. Let machine 1 to t be t empty machines each maintains $s/10$ "positions", i.e. machine 1 has "positions" 1 to $s/10$, machine 2 has "positions" $s/10 + 1$ to $2s/10$, and so on. Let $t \cdot s/10 = \Theta(n)$. The machine which holds tuple $(\text{“}S_i\text{”}, x)$ sends the tuple $(\text{“}S_i\text{”}, x)$ to the "position" $\text{pos}(\text{“}S_i\text{”}, x) - s_i + 1$, and sends the tuple $(\text{“}S_{i,s_i}\text{”}, x)$ to the "position" $\text{pos}(\text{“}S_i\text{”}, x)$. Then each machine $i \in [t]$ scans its "positions". If a "position" received a tuple, the machine marks that "position" as "1". Otherwise, the machine marks that position as "0". Now we can apply the predecessor algorithm (See Theorem 32.7.3) such that each empty "position" learns its predecessor tuple. If the predecessor tuple of an empty "position" l is $(\text{“}S_i\text{”}, x)$, and the predecessor tuple is at "position" l', then create a tuple $(\text{“}S_{i,l-l'}\text{”}, x)$ at this empty position. Thus, at the end of all the computations, $S_{1,1}, S_{1,2}, \cdots, S_{1,s_1}, S_{2,1}, S_{2,2}, \cdots, S_{2,s_2}, \cdots, S_{k,s_k}$ are stored on the system.

Indexing elements in sets Suppose we have k sets $S_1, S_2, \cdots, S_k$ stored in the system. The goal is to compute a mapping f such that $\forall i \in [k], x \in S_i$, x is the $f(S_i, x)^{\text{th}}$ element of

S_i.

To achieve this goal, we can sort (See Theorem 32.7.1) all the tuples such that the elements from the same set are stored consecutively on several machines. Then we can run indexing algorithm (See Theorem 32.7.2) to compute the global index of each tuple. In the next, each machine scans its local data. If $(\text{“}S_i\text{”}, x)$ is in the local memory, and x is the first element of S_i, then the machine marks this tuple as “1”. For other tuples in the local memory, the machine marks them as “0”. Then we can invoke predecessor algorithm (See Theorem 32.7.3) on all the tuples. At the end of the computation, each machine scans its all tuples. For a tuple $(\text{“}S_i\text{”}, x)$ with global index l, the machine determine the index of x in S_i based on the global index l' of its predecessor $(\text{“}S_i\text{”}, x)$. Precisely, the machine creates a tuple $(\text{“}f\text{”}, ((\text{“}S_i\text{”}, x), l - l' + 1))$ stored in the memory. Thus at the end of the computation, the desired mapping f is stored in the system.

Set merging Suppose we need to merge several sets $S_1, S_2, \cdots, S_k$ stored on the system, i.e. create a new set $S = \bigcup_{i=1}^{k} S_i$. To implement this operation, each machine scans its local memory. If there is a tuple $(\text{“}S_i\text{”}, x)$ in its memory, then it creates a tuple $(\text{“}S\text{”}, x)$. Finally, we just need to remove all the duplicates.

Set membership Suppose we have k sets $S_1, S_2, \cdots, S_k$ stored in the system. There is an another set $Q = \{(x_1, y_1), \cdots, (x_q, y_q)\}$ also stored in the system where x_i is the name of a set S, and y_i is an item. The goal is to answer whether y_i is in S.

To achieve this, we can firstly sort all the tuples. For tuple with form $(\text{“}S_i\text{”}, x)$, the first key is S_i, the second key is x, and the third key is $-\infty$ which has the highest priority.

For tuple with form $(\text{“}Q\text{”}, (x, y))$, the first key is x, the second key is y, and the third key is ∞ which has the lowest priority. The comparison in the sorting procedure firstly compare the first key, then the second key, and finally the third key. After sorting, for each tuple with form $(\text{“}S_i\text{”}, x)$, we mark it as “1”. For each tuple with form $(\text{“}Q\text{”}, (x, y))$, we mark it as “0”. Now we can apply the predecessor algorithm (See Theorem 32.7.3). For each tuple $(\text{“}Q\text{”}, (x, y))$, if its predecessor is $(\text{“}S\text{”}, y)$ where x is the name of “S”, then we create a tuple $(\text{“}f\text{”}, ((x, y), 1))$; Otherwise, we create a tuple $(\text{“}f\text{”}, ((x, y), 0))$. Thus, at the end of the computation, there is a mapping f stored on the system such that for each $(x, y) \in Q$, if x is the name of some set S_i, and $y \in S_i$, then $f(x, y) = 1$; Otherwise $f(x, y) = 0$.

32.7.4 Mapping Operations

In this section, we introduce some MPC model operations for mapping. The most important operation is called Multiple queries.

Multiple queries We have k sets $S_1, S_2, \cdots, S_k$ stored in the system. Without loss of generality, $S_1, S_2, \cdots, S_t$ ($t \leq k$) are sets representations of mappings (See Definition 32.7.1) $f_1 : U_1 \to H_1, f_2 : U_2 \to H_2, \cdots, f_t : U_t \to H_t$ respectively. When a machine does local computation, it may need to query some values which are in the form $f_i(u)$ for some $u \in U_i$. The following lemma shows that we can answer all the such queries simultaneously in constant number of rounds in $(0, \delta) - \text{MPC}$ model for all constant $\delta \in (0, 1)$. It means that we can use constant number of rounds to simulate concurrent read operations on a shared memory where $S_1, \cdots, S_k$ are stored in the shared memory.

Lemma 32.7.4 (Multiple queries)**.** *Let $\delta \in (0, 1)$ be an arbitrary constant. There is a constant number of rounds algorithm $\mathcal{A}$ in $(0, \delta) - \text{MPC}$ model which satisfies the following properties. The input of $\mathcal{A}$ contains two parts. The first part are k sets $S_1, S_2, \cdots, S_k$ stored (See Section 32.7.2 for data organization of sets) on the input machines, where $S_1, S_2, \cdots, S_t$ ($t \leq k$) are sets representations of mappings (See Definition 32.7.1) $f_1 : U_1 \to H_1, f_2 : U_2 \to H_2, \cdots, f_t : U_t \to H_t$ respectively. The second part is a set*

$$Q = \{(x_1, y_1, z_1), (x_2, y_2, z_2), \cdots, (x_q, y_q, z_q)\}$$

stored on the input machines, where $\forall (x, y, z) \in Q$, x is the name "f_i" of the mapping f_i for some $i \in [t]$, y is an element in U_i, and z is the index of the input machine which holds the element (x, y, z) of Q. The total input size $n = |Q| + \sum_{i=1}^{k} |S_i|$. The output machines

are all the input machines. $\forall i \in [k], x \in S_i$*, if the element* x *of* S_i *is held by the input (also output) machine* j*, then at the end of the computation, the element* x *of* S_i *should still be held by the output (also input) machine* j*. Let* Q' *be the set* $\{(x, y, z, w) \mid \exists (x, y, z) \in Q, w = f_i(y)$*, where* x *is the name of* $f_i\}$*. At the end of the computation,* Q' *is stored on the output (also input) machines such that* $\forall (x, y, z, w) \in Q'$*, the element* (x, y, z, w) *of* Q' *is held by the machine* z*.*

Proof. The idea is that we can firstly use sorting (See Theorem 32.7.1) to make queries and the corresponding values be stored consecutively in several machines. The issue remaining is that there may be many queries queried the same position such that some queries may not be stored in the machine which holds the corresponding value. In this case, we need to find the predecessor by invoking the algorithm shown in Theorem 32.7.3. □

The Multiple queries algorithm is shown as the following:

Multiple Queries Algorithm:

- **Setups:**
  - There are $3p = \Theta(n^\delta)$ machines indexed from 1 to $3p$ each with local memory size $s = \Theta(n^\delta)$.
  - The machine with index from $2p+1$ to $3p$ are input/output machines.
  - Sets $S_1, S_2, \cdots, S_k, Q$ are stored on machine $2p+1$ to $3p$. ▷ Corresponding to Lemma 32.7.4
- **The first round:**
  - Machine $i \in \{2p+1, \cdots, 3p\}$ scans its local memory, and send all the tuples with form $(\text{“}f_j\text{”}, (x, y))$ or $(\text{“}Q\text{”}, (x, y, z))$ to machine $i - p$, where “f_j” is the name of f_j (also S_j) for $j \in [t]$. Until the end of the computation, machine i sends itself messages to keep its local data.
- **Using constant number ($O(1/\delta)$) of rounds to sort:**
  - Use machine 1 to $2p$ to sort all the tuples stored on machine $p+1$ to $2p$, and thus at the end of this stage, machine $p+1$ to $2p$ holds sorted tuples. For tuple with the form $(\text{“}f_j\text{”}, (x, y))$, the first key value is “f_j”, the second key value is x and the third key value is $-\infty$ which is the highest priority. For tuple with form $(\text{“}Q\text{”}, (x, y, z))$, the first key value is x, the second key value is y, and the third key value is ∞ which is the lowest priority. The comparison in the sorting is: Firstly compare the first key. If they are the same, then compare the second key. If they are still the same, compare the third key.
- **Using constant number ($O(1/\delta)$) of rounds to find predecessors:**
  - Machine $p+1$ to $2p$ scans its local memory. For a tuple in the form $(\text{“}f_j\text{”}, (x, y))$, the machine marked it as “1”. For a tuple in the form $(\text{“}Q\text{”}, (x, y, z))$, the machine marked it as “0”.
  - Machine 1 to $2p$ together invoke the Predecessor algorithm (Theorem 32.7.3), where the input is on machine $p+1$ to machine $2p$.
- **The last round:**
  - Machine $p+1$ to $2p$ scans its local memory. For each tuple with form $(\text{“}Q\text{”}, (x, y, z))$, it sends machine z a tuple $(\text{“}Q'\text{”}, (x, y, z, w))$, where x is the name of f_j, and $w = f_j(y)$.

32.7.5 Sequence Operations

In this section, we introduce some MPC model operations for sequence.

Sequence standardizing Suppose there is a sequence A, and one of its set representation (see Definition 32.7.2) S is stored in the system. The goal is to modify the set S such that S is a standard set representation of A.

We can compute the index (see **Indexing elements in sets** in Section 32.7.3) of elements in S. Then for each element $(x, y) \in S$, we can query (see **Multiple queries** in Section 32.7.4) the index of (x, y) in S. Suppose the index is i, we modify the tuple $(\text{“}S\text{”}, (x, y))$ to $(\text{“}S\text{”}, (i, y))$.

Sequence duplicating Suppose there is a sequence $A = (a_1, a_2, \cdots, a_s)$, and one of its set representation (see Definition 32.7.2) S is stored in the system. Furthermore, there is a mapping $f : [s] \to \mathbb{Z}_{\geq 0}$ which is also stored in the system. The goal is to get a set S' stored in the system such that S' is a set representation of the sequence:

$$(\underbrace{a_1, a_1, \cdots, a_1}_{f(1) \text{ times}}, \underbrace{a_2, a_2, \cdots, a_2}_{f(2) \text{ times}}, \cdots, \underbrace{a_s, a_s, \cdots, a_s}_{f(s) \text{ times}}).$$

Firstly, we can standardize (see the above paragraph **Sequence standardizing**) the set S. Then for each tuple $(\text{“}S\text{”}, (i, a_i))$, we create a tuple $(\text{“}S_i\text{”}, a_i)$, and we can query (see **Multiple queries** in Section 32.7.4) the value of $f(i)$. Then we can copy (see **Copies of sets** in Section 32.7.3) set S_i $f(i)$ times. For each tuple $(\text{“}S_{i,j}\text{”}, a_i)$, we create a tuple $(\text{“}S'\text{”}, ((i, j), a_i))$. Then we can compute the index (see **Indexing elements in sets** in Section 32.7.3) of each element in S'. For each tuple $(\text{“}S'\text{”}, ((i, j), a_i))$, we can query

(see **Multiple queries** in Section 32.7.4) the index i' of it, and then modify the tuple as $(\text{“}S\text{”}, (i', a_i))$.

Sequence insertion Suppose there are $k+1$ sequences $A = (a_1, a_2, \cdots, a_s), A_1, \cdots, A_k$ which have sets representations (see Definition 32.7.2) $S, S_1, \cdots, S_k$ respectively and stored on the system. There is also a mapping $f : [k] \to \{0\} \cup [s]$ stored on the system where $\forall i \neq j \in [k], f(i) \neq f(j)$. The goal is to insert each sequence A_i into the sequence A, and A_i should be between the element $a_{f(i)}$ and $a_{f(i)+1}$.

Firstly, we can standardize (see **Sequence standardizing** in Section 32.7.3) S. Then we can compute the total size (see **Sizes of sets** in Section 32.7.3) $N = |S|+|S_1|+\cdots+|S_k|+1$. For each tuple $(\text{“}S\text{”}, (i, a_i))$, we can modify it as $(\text{“}S\text{”}, (i \cdot N, a_i))$. For each tuple $(\text{“}S_i\text{”}, (j, a_{ij}))$, we query (see **Multiple queries** in Section 32.7.4) the value of $f(i)$, then create a tuple $(\text{“}S\text{”}, (f(i) \cdot N + j, a_{ij}))$.

32.7.6 Multiple Tasks

In this section, we show that if the entire computational tasks consist of some independent small computational tasks, then we are able to schedule the machines such that the small computational tasks can be computed simultaneously.

Task and multiple tasks problem A computational task here is running a specific algorithm on specific input data.

There are k sets $S_1, S_2, \cdots, S_k$ stored in the system. Let $n = \sum_{i=1}^{k} |S_i|$ be the total input size. There are h independent computational tasks $T_1, T_2, \cdots, T_h$. Each task T_i needs to take some sets $\mathcal{S}_i \subseteq \{S_1, S_2, \cdots, S_k\}$ as its input, and is running a $(\gamma_i, \delta_i) - \text{MPC}$ algorithm in r_i rounds where $\gamma_i \in \mathbb{R}_{\geq 0}$, constant $\delta_i \in (0, 1)$. $\forall i \in [h]$, let $n_i = \sum_{S \in \mathcal{S}_i} |S|$ be the input size of task T_i. Without loss of generality, we can assume that the input of different tasks are disjoint. Otherwise we can use sets copying technique (See Section 32.7.3) to generate different copies of input sets for the tasks shared the same input set. The goal here is to use the small number of rounds to finish all the tasks. Since we can always use sorting and indexing to extract the desired input data. The most naive way is to compute the tasks one-by-one. This can be trivially done in $r = O(\sum_{i=1}^{h} r_i)$ rounds in $(\gamma, \delta) - \text{MPC}$ model for $\gamma = \log_n(h) + \max_{i \in [h]} \gamma_i, \delta = \max_{i \in [h]} \delta_i$. Here we show how to compute all the tasks simultaneously in $r = O(\max_{i \in [h]} r_i)$ rounds in $(\gamma, \delta) - \text{MPC}$ model for $\gamma = \log_n(m) - 1, \delta = \max_{i \in [h]} \delta_i$, where $m = \Theta(n + \sum_{i=1}^{h} n_i^{1+\gamma_i})$.

Each machine scans its local memory. If the machine holds a tuple $(\text{“}S_i\text{”}, x)$, and S_i is a part of input of task T_j, then it creates a tuple $(\text{“}W_j\text{”}, (\text{“}S_i\text{”}, x))$. Thus, at the end of this step, there are additional h sets $W_1, W_2, \cdots, W_h$ stored in the system. Here $W_i, i \in [h]$

contains all the information of input data of task T_i. Then we can compute a mapping f such that $\forall i \in [h], f(W_i) = |W_i|$ (see Section 32.7.3). Thus, we know the input size of each task. Then each machine scans its local memory. If the machine holds a tuple $(\text{“}f\text{”}, (\text{“}W_i\text{”}, |W_i|))$, then it creates a tuple $(\text{“}H_i\text{”}, |W_i|)$, i.e. a set $H_i = \{|W_i|\}$. Then for each set $H_i = \{|W_i|\}, i \in [h]$, we can copy (see Section 32.7.3) it $s_i = c \cdot |W_i|^{1+\gamma_i}$ times for a sufficiently large c to get sets $H_{i,1} = H_{i,2} = \cdots = H_{i,s_i} = |W_i|$. Each set $H_{i,j}$ is just a placeholder of one unit working space of the task T_i. Thus, the number of copies of the set H_i is the total space needed for the task T_i. We can sort all the tuples $(\text{“}H_{i,j}\text{”}, |W_i|)$ on machines with index in $I = \{2, 5, 8, 11, \cdots, 3p-1\}$, where local memory $s = \Theta(n^\delta)$, total required memory $m = \Theta(n + \sum_{i=1}^{h} n_i^{1+\gamma_i})$, and $p = \Theta(m/s)$ For each machine with index $q \in I$, the tuples on that machine must be in the following form

$$(\text{“}H_{i,j}\text{”}, |W_i|), (\text{“}H_{i,j+1}\text{”}, |W_i|), \cdots, (\text{“}H_{i,s_i}\text{”}, |W_i|), (\text{“}H_{i+1,1}\text{”}, |W_{i+1}|), \cdots, (\text{“}H_{i+1,s_{i+1}}\text{”}, |W_{i+1}|),$$
$$(\text{“}H_{i+2,1}\text{”}, |W_{i+2}|), \cdots, (\text{“}H_{i+2,s_{i+2}}\text{”}, |W_{i+2}|), \cdots, (\text{“}H_{i',1}\text{”}, |W_{i'}|), \cdots (\text{“}H_{i',j'}\text{”}, |W_{i'}|).$$

Then machine q just sends all the tuples $(\text{“}H_{i,j}\text{”}, |W_i|), (\text{“}H_{i,j+1}\text{”}, |W_i|), \cdots, (\text{“}H_{i,s_i}\text{”}, |W_i|)$ to machine $q-1$, and sends all the tuples $(\text{“}H_{i',1}\text{”}, |W_{i'}|), (\text{“}H_{i',2}\text{”}, |W_{i'}|), \cdots (\text{“}H_{i',j'}\text{”}, |W_{i'}|)$ to machine $q+1$. Thus, $\forall i \in [h]$,

1. either all the $H_{i,1}, H_{i,2}, \cdots, H_{i,s_i}$ are stored on consecutive machines, machine q to machine q', and any of machine q to machine q' does not hold other tuples,
2. or there is a unique machine q which holds all the sets $H_{i,1}, H_{i,2}, \cdots, H_{i,s_i}$.

For each machine $q \in [3p]$, if $H_{i,1}$ is held by machine q, then it creates a tuple $(\text{“st”}, (\text{“}T_i\text{”}, q))$. If H_{i,s_i} is held by machine q, then it creates a tuple $(\text{“ed”}, (\text{“}T_i\text{”}, q))$. The mapping st, ed

then are stored in the system, where $\mathrm{st}(T_i)$ is the index of the first machine assigned to task T_i, and $\mathrm{ed}(T_i)$ is the index of the last machine assigned to task T_i. Recall that W_i contains all the information of the input data to task T_i. The remaining task is to move the input data of task T_i to the machines with index from $\mathrm{st}(T_i)$ to $\mathrm{ed}(T_i)$. According to Section 32.7.3, we can compute a mapping f', such that $f'(W_i, x)$ records the index of $x \in W_i$ in set W_i. Now, each machine scans its local memory. For each tuple $(\text{“}W_j\text{”}, (\text{“}S_i\text{”}, x))$, the machine needs to query the value of $f'(W_j, (\text{“}S_i\text{”}, x))$, the value of $\mathrm{st}(T_j)$ and the value of $\mathrm{ed}(T_j)$. By Lemma 32.7.4, these queries can be handled simultaneously in constant number of rounds. Then the machine can send the tuple $(\text{“}S_i\text{”}, x)$ to the corresponding machine based on the value of $f'(W_j, (\text{“}S_i\text{”}, x))$, $\mathrm{st}(T_j)$, and $\mathrm{ed}(T_j)$. Finally, $\forall i \in [h]$, since $\delta \geq \delta_i$ and $(\mathrm{ed}(T_i) - \mathrm{st}(T_i) + 1) \cdot s = \Theta(n_i^{1+\gamma_i})$, the machines with index from $\mathrm{st}(T_i)$ to $\mathrm{ed}(T_i)$ can simulate task T_i in r_i number of rounds.

32.8 Implementations in MPC Model

In this section, we show how to implement all the previous batch algorithms in MPC model.

32.8.1 Neighbor Increment Operation

Lemma 32.8.1. *Let graph $G = (V, E), n = |V|, N = |V| + |E|$ and $m = \Theta(N^\gamma)$ for some arbitrary $\gamma \in [0, 2]$.* NeighborIncrement(m, G) *(Algorithm 32.1) can be implemented in $(\gamma, \delta) -$ MPC model for any constant $\delta \in (0, 1)$. Furthermore, the parallel running time is $O(r)$, where r is the number of iterations (see Definition 32.4.1) of* NeighborIncrement(m, G).

Proof. To implement line 7, we can create a tuple $(\text{“}S_v^{(0)}\text{”}, u)$ for each tuple $(\text{“}E\text{”}, (v, u))$. Then for each $(\text{“}S_v^{(0)}\text{”}, u)$ we can compute the index (see **Indexing elements in sets** and **Multiple queries**) of u in set $S_v^{(0)}$. If the index of u in set $S_v^{(0)}$ is at least $\lceil (m/n)^{1/2} \rceil$, then delete u from $S_v^{(0)}$, i.e. delete the tuple $(\text{“}S_v^{(0)}\text{”}, u)$.

Now let us discuss how to implement line 14 and line 17 in the i^{th} iteration. Firstly, we can compute the size of every set stored in the system (see **Sizes of sets**). Then for each tuple $(\text{“}S_v^{(i-1)}\text{”}, u)$, the corresponding machine queries (see **Multiple queries**) the size of $S_u^{(i-1)}$. If $|S_u^{(i-1)}| \geq \lceil (m/n)^{1/2} \rceil$, then create a tuple $(\text{“temp}_v^i\text{”}, u)$. We can index (see **Indexing elements in sets**) all the elements in set temp_v^i, and only keep the element with index 1. Thus, temp_v^i has a only element u, and we need to create a set $S_v^{(i)} = S_u^{(i-1)}$. Notice that there may be many $v \in V$ which needs need to implement $S_v^{(i)} = S_u^{(i-1)}$. Thus, for each tuple $(\text{“temp}_v^i\text{”}, u)$, we create a tuple $(\text{“target}_u^i\text{”}, v)$. $v \in \text{target}_u^i$ means that $S_v^{(i)}$ needs a copy of $S_u^{(i-1)}$. Thus, $|\text{target}_u^i|$ means that $S_u^{(i-1)}$ needs to copy $|\text{target}_u^i|$ times. For each tuple

(“$S_u^{(i-1)}$”, x), the machine queries (see **Multiple queries**) the size of target_u^i. Then each set $S_u^{(i-1)}$ can be copied (see **Copies of sets**) $|\text{target}_u^i|$ times. For each tuple (“target_u^i”, v), we query (see **Multiple queries**) the index (see **Indexing elements in sets**) of v in set target_u^i, and then create a tuple (“f^i”, ((“target_u^i”, x), v)), where x is the index of v in target_u^i. Thus f^i is a mapping such that $f^i(\text{target}_u^i, x)$ is the x^{th} element in target_u^i. For each tuple (“$S_{u,j}^{(i-1)}$”, x), we query (see **Multiple queries**) the value $v = f^i(\text{target}_u^i, j)$, and then create a tuple (“$S_v^{(i)}$”, x), and a tuple (“$S_v^{(i)}$”, v). We then remove the duplicates (see **Duplicates removing**) of elements of for every set $S_v^{(i)}$. For each tuple (“temp_v^i”, u), query (see **Multiple queries**) the size (see **Sizes of sets**) of $S_v^{(i)}$ and $S_u^{(i-1)}$. If $|S_v^{(i)}| > |S_u^{(i-1)}|$, then we create a tuple (“g^i”, (v, (u, “delete”))); Otherwise, create a tuple (“g^i”, (v, (u, “keep”))). Finally, for each tuple ($S_v^{(i)}, x$), we query (see **Multiple queries**) $(u, o) = g^i(v)$, if $u = x$ and $o =$ “delete", the machine deletes the tuple ($S_v^{(i)}, x$).

Next, let us discuss how to implement line 20. Similar as before, we can compute the size of every set stored in the system (see **Sizes of sets**). Then for each tuple (“$S_v^{(i-1)}$”, u), the corresponding machine queries (see **Multiple queries**) the size of $S_u^{(i-1)}$. If $|S_u^{(i-1)}| \geq \lceil (m/n)^{1/2} \rceil$, then create a tuple (“$\text{temp}_v^i$”, u). For each tuple (“V”, v), we can create a tuple (“temp_v^i”, null). Then for each tuple (“V”, v) we can query (see **Multiple queries**) the size (see **Sizes of sets**) of temp_v^i. If $|\text{temp}_v^i| = 1$, then we create a tuple (“f'^i”, 1); Otherwise, we create a tuple (“f'^i”, 0). Thus, mapping f'^i is stored in the system, and $f'^i(v) = 1$ if and only if $\forall u \in S_v^{(i-1)}, |S_u^{(i-1)}| < \lceil (m/n)^{1/2} \rceil$. For each tuple (“$S_v^{(i-1)}$”, u), we query (see **Multiple queries**) the value $f'^i(v)$. If $f'^i(v) = 1$, we create a tuple (“target_u^i”, v). Thus, $v \in \text{target}_u^i$ means that $S_u^{(i-1)}$ should be a part of $S_v^{(i)}$. $|\text{target}_u^i|$ means that $S_u^{(i-1)}$ needs to copy $|\text{target}_u^i|$ times. For each tuple (“$S_u^{(i-1)}$”, v), we query (see **Multiple queries**) the size (see **Sizes of**

sets) of target_u^i. Then we can copy (see **Copies of sets**) each set $S_u^{(i-1)}$ $|\text{target}_u^i|$ times. Then for each tuple $(\text{“target}_u^i\text{”}, v)$, we can query (see **Multiple queries**) the index x (see **Indexing elements in sets**) of v in set target_u^i, and then create a tuple $(\text{“}f^i\text{”}, ((\text{“target}_u^i\text{”}, x), v))$ which means that the x^{th} element of target_u^i is $f^i(\text{target}_u^i, x) = v$. For each tuple $(\text{“}S_{u,j}^{(i-1)}\text{”}, x)$, we query (see **Multiple queries**) the value $v = f^i(\text{target}_u^i, j)$, and then create a tuple $(\text{“}S_v^{(i)}\text{”}, x)$. We then remove the duplicates (see **Duplicates removing**) of elements of for every set $S_v^{(i)}$.

Finally, let us consider how to implement line 24. It is very simple, we only need to query the sizes of sets. For each tuple $(\text{“}V\text{”}, v)$, query (see **Multiple queries**) the size (see **Sizes of sets**) of $S_v^{(i)}$ and $S_v^{(i-1)}$, if v satisfies the condition, create a tuple $(\text{“}Done\text{”}, v)$. Every machine queries (see **Multiple queries**) the size (see **Sizes of sets**) of Done. If it is $|V|$, then all the machines know that they finish the loop. In the end, for each tuple $(S_v^{(r)}, u)$ we create tuples $(\text{“}E'\text{”}, (u, v)), (\text{“}E'\text{”}, (v, u))$, and for each tuple $(\text{“}E\text{”}, (u, v))$ we create tuple $(\text{“}E'\text{”}, (u, v))$. Then we then remove the duplicates (see **Duplicates removing**) of elements of E.

In the i^{th} iteration, we only need to maintain sets $V, E, S_v^{(i-1)}$. Since all the copy operation will create at most $n \cdot (m/n)^{1/2} \cdot (m/n)^{1/2} = m$ tuples, the total space needed is $\Theta(m)$ plus the space needed to maintain $V, E, S_v^{(i)}$. By Property 4 of Lemma 32.4.1, $|S_v^{(i)}| \leq m/n$. Thus, the total space is $\Theta(m) + |V| + |E| + \sum_{v \in V} |S_v^{(i)}| = \Theta(m) + N = \Theta(m)$.

The above implementation shows that the parallel time is $O(r)$, where r is the number of iterations (see Definition 32.4.1). □

32.8.2 Tree Contraction Operation

In this section, we show how to implement Algorithm 32.2 in MPC model.

Lemma 32.8.2. *Let graph $G = (V, E)$ and* par $: V \to V$ *be a set of parent points (see Definition 32.4.2) on the vertex set V.* TreeContraction(G, par) *(Algorithm 32.2) can be implemented in $(0, \delta) -$* MPC *model for any constant $\delta \in (0, 1)$. Furthermore, the parallel running time is $O(r)$, where r is the number of iterations (see Definition 32.4.5) of* TreeContraction(G, par).

Proof. Let $N = |V| + |E|$. Then the total space is $\Theta(N)$.

Initially, each machine scans its local memory. If there is a tuple $(\text{“}V\text{”}, v)$, then it queries the value of part(v). It needs $O(1)$ parallel time to answer all the queries (see Multiple queries in Lemma 32.7.4). Then the machine creates a tuple $(\text{“}g^{(0)}\text{”}, (v, \text{part}(v)))$. Thus, in the initialization stage, mapping $g^{(0)}$, par, set V, E are stored in the system.

In the l^{th} iteration, Each machine scans its local memory. If there is a tuple $(\text{“}V\text{”}, v)$, then it queries the value of $g^{(l-1)}(v)$. This can be done by Multiple queries. Then it queries the value of part$(g^{(l-1)}(v))$. This can also be done by Multiple queries. If $\text{part}(g^{(l-1)}(v)) = g^{(l-1)}(v)$, it creates a tuple $(\text{“Done”}, v)$. Then the machines can compute the sizes (see Section 32.7.3) of V and Done. Each machine queries the size of V and Done. This can be done by Multiple queries. Then if $|V| = |\text{Done}|$, every machine knows that the iterations are finished. Otherwise, the machine which holds $(\text{“}V\text{”}, v)$ queries the value of $g^{(l-1)}(g^{(l-1)})(v)$. This can be done by Multiple queries. And then it creates a tuple $(\text{“}g^{(l)}\text{”}, (v, g^{(l-1)}(g^{(l-1)})(v)))$.

At the end, if a machine holds a tuple $(\text{“}V\text{”}, v)$, then the queries part(v). If $v =$

part(v), it creates a tuple $(\text{“}V'\text{”}, v)$. If a machine holds a tuple $(\text{“}E\text{”}, (u, v))$, then it queries $g^{(r)}(u), g^{(r)}(v)$, and creates a tuple $(\text{“}E'\text{”}, (g^{(r)}(u), g^{(r)}(v)))$.

Since at the end of each iteration l, the system only stores mappings par : $V \to V, g^{(r)} : V \to V$, and sets V, E, the total space used is at most $O(N)$. Thus, we can implement the algorithm in $(0, \delta) -$ MPC model.

The total parallel time is $O(r)$. By Corollary 32.4.8, $r = O(\text{dep}(\text{par}))$. Thus, the total parallel time is $O(\text{dep}(\text{par}))$. □

32.8.3 Graph Connectivity

Theorem 32.8.3. *Let graph $G = (V, E), n = |V|, N = |V| + |E|$ and $m = \Theta(N^\gamma)$ for some arbitrary $\gamma \in [0, 2]$. Let $r > 0$ be a round parameter.* Connectivity(G, m, r) *(Algorithm 32.3) can be implemented in $(\gamma, \delta) -$ MPC model for any constant $\delta \in (0, 1)$. Furthermore, the parallel running time is $O(R)$, where R is the total number of iterations (see Definition 32.4.6) of* Connectivity(G, m, r).

Proof. Initially, we store sets V_0, E_0, V, E and mapping h_0 in the system. Now consider the i^{th} round. Due to Lemma 32.8.1, line 9 can be implemented in total space $\Theta(m)$ and with $O(k_i)$ parallel time, where k_i is the number of iterations (See Definition 32.4.1) of NeighborIncrement(m, G_{i-1}). To store V_i' and E_i', we need total space $\Theta(m)$. Line 10 can be implemented by operations described in **Sizes of sets** and **Multiple queries** (see Section 32.7). Line 11 can be implemented by the operations described in **Set membership** and **Multiple queries**. To implement line 14, for each tuple $(\text{“}V_i''\text{”}, v)$, we can create a tuple $(\text{“}l_i\text{”}, (v, x))$ where $x = 1$ with probability p_i, $x = 0$ with probability $1 - p_i$. To calculate p_i, the machine only needs to know n_{i-1}. This can be done by the operations described in **Sizes of sets** and **Multiple queries**. Line 15 and line 16 can be implemented by operations described in **Set membership** and **Multiple queries**. For line 17, set $L_i \cap (\Gamma_{G_i'}(v) \cup \{v\})$ can be computed by operations described in **Set membership** and **Multiple queries**. Then, by operations in **Indexing elements in sets** and **Multiple queries**, we can get $\min_{u \in L_i \cap (\Gamma_{G_i'}(v) \cup \{v\})} u$. Finally, by operation described in **Multiple queries**, $\forall v \in V_i''$ with $v \notin L_i$, the tuple $(\text{“par}_i\text{”}, (v, x))$ can be created, where $x = \min_{u \in L_i \cap (\Gamma_{G_i'}(v) \cup \{v\})} u$. Due to Lemma 32.8.2, line 18 can be implemented in total $\Theta(m)$ space and $O(r_i')$ parallel running

time, where r'_i is the number of iterations (see Definition 32.4.5) of TreeContraction(G''_i, par_i). Line 21 can be implemented by operations in **Set membership**, **Indexing elements in sets** and **Multiple queries**. Line 22 can be implemented by operations in **Set membership** and **Multiple queries**. Line 23 can be implemented by **Multiple queries**. For other $v \in V$ with $h_i(v) = \text{null}$ assigned by line 8, we can use the operations in **Set membership** and **Multiple queries** to find those v, and create a tuple $(\text{“}h_i\text{”}, v, \text{null})$.

Thus, in the i^{th} round, the parallel time needed is $O(k_i + r'_i)$. At the end of the i^{th} round, we only need to keep sets V_i, E_i, V, E and mapping h_i in the system. It will take total space at most $O(m)$.

Due to Lemma 32.8.2, line 26 can be implemented in at most $O(m)$ total space and $O(\log r)$ parallel time.

Thus, the total parallel time is $O(\log r + \sum_{i=1}^{r}(k_i + r'_i)) = O(\sum_{i=1}^{r}(k_i + r'_i))$. By definition 32.4.6, the total parallel time is $O(R)$, where R is the total number of iterations of CONNECTIVITY(G, m, r). The total space in the computation is always at most $\Theta(m)$. □

Here, we are able to conclude the following theorem for graph connectivity problem.

Theorem 32.8.4. *For any $\gamma \in [0, 2]$ and any constant $\delta \in (0, 1)$, there is a randomized $(\gamma, \delta) -$ MPC algorithm (see Algorithm 32.3) which can output the connected components for any graph $G = (V, E)$ in $O(\min(\log D \cdot \log(1/\gamma'), \log n))$ parallel time, where D is the diameter of G, $n = |V|$, $N = |V| + |E|$ and $\gamma' = (1 + \gamma) \log_n \frac{2N}{n^{1/(1+\gamma)}}$. The success probability is at least 0.98. In addition, if the algorithm fails, then it will return* FAIL.

Proof. The implementation of Algorithm 32.3 in MPC model is shown by Theorem 32.8.3.

The correctness of Algorithm 32.3 is proved by Theorem 32.4.9. The total parallel time of Algorithm 32.3 is proved by Theorem 32.4.15. □

32.8.4 Algorithms for Local Shortest Path Trees

In this section, we mainly explained how to implement local shortest path tree algorithms described in Section 32.5.1 and Section 32.5.2.

Lemma 32.8.5. *Let $G = (V, E)$ be an undirected graph, $s_1, s_2 \in \mathbb{Z}_{\geq 0}$, and $v \in V$. Let $\widetilde{T} = (V_{\widetilde{T}}, \mathrm{par}_{\widetilde{T}})$ with root v and radius s_1 be a local complete shortest path tree (see Definition 32.5.3) in G, and $\mathrm{dep}_{\widetilde{T}} : V_{\widetilde{T}} \to \mathbb{Z}_{\geq 0}$ be the depth of every vertex in $\widetilde{T}$. $\forall u \in V_{\widetilde{T}}$, let $T(u)$ with root u and radius s_2 be a local complete shortest path tree in G, and $\mathrm{dep}_{T(u)} : V_{T(u)} \to \mathbb{Z}_{\geq 0}$ be the depth of every vertex in $T(u)$. Then* TreeExpansion$(\widetilde{T}, \mathrm{dep}_{\widetilde{T}}, \{T(u) \mid u \in V_{\widetilde{T}}\}, \{\mathrm{dep}_{T(u)} \mid u \in V_{\widetilde{T}}\})$ *(Algorithm 32.4) can be implemented in $(0, \delta) -$ MPC model for any constant $\delta \in (0, 1)$ in $O(1)$ parallel time.*

Proof. For line 3, we apply operation shown in **Copies of sets** to copy each $V_{T(u)}$, then we can merge (see **Set merging**) all the copies to get $V_{\widehat{T}}$. To implement line 4 and line 5, we only need to apply the operation shown in **Multiple queries**. To implement line 6, for each tuple $(\text{“}V_{T(u)}\text{”}, x)$, we can firstly check whether $x \in V_{\widehat{T}} \setminus V_{\widetilde{T}}$ by operations described in **Set membership** and **Multiple queries**. If $x \in V_{\widehat{T}} \setminus V_{\widetilde{T}}$, then we can query the values of $\mathrm{dep}_{\widetilde{T}}(u)$ and $\mathrm{dep}_{T(u)}(x)$ by operations shown in **Multiple queries**. Then we create a tuple $(\text{“temp}_x\text{”}, (\mathrm{dep}_{\widetilde{T}}(u) + \mathrm{dep}_{T(u)}(x), u))$. By **Indexing elements in sets** and **Multiple queries**, we can find the element with the smallest index in set temp_x, and thus that element is $(\mathrm{dep}_{\widetilde{T}}(u_x) + \mathrm{dep}_{T(u_x)}(x), u_x)$. Finally, the remaining things in line 6 and line 7 can be done by the operations described by **Multiple queries**.

For all the operations, the total space is always linear. The parallel time needed for the above operations is also a constant. □

Lemma 32.8.6. *Let graph $G = (V, E), n = |V|, N = |V| + |E|$ and $m = \Theta(N^\gamma)$ for some arbitrary $\gamma \in [0, 2]$.* MultiRadiusLCSPT(G, m) *(Algorithm 32.5) can be implemented in $(\gamma, \delta) -$* MPC *model for any constant $\delta \in (0, 1)$. Furthermore, the parallel running time is $O(r)$, where r is the number of iterations (see Definition 32.5.4) of* MultiRadiusLCSPT(G, m).

Proof. To implement line 4 to line 6, we can scan all the tuples $(\text{“}E\text{”}, (u, v))$, then query the size of $\{v\} \cup \Gamma_G(v)$ and the size of $\{u\} \cup \Gamma_G(u)$, where these operations are described in **Sizes of sets** and **Multiple queries.** Then based on the sizes, we decide whether we need to create the corresponding tuples for $V_{T_0(v)}, V_{T_0(u)}, \text{par}_{T_0(u)}, \text{part}(T_0(v))$.

Now consider the main loop. We focus on the i^{th} round. Line 12 can be implemented by the operation described in **Multiple queries**. To implement line 13, for each tuple $(\text{“}V_{T_{i-1}(v)}\text{”}, u)$, we can query (see **Multiple queries**) whether $T_{i-1}(u)$ is null. If $T_{i-1}(u)$ is null, then we create a tuple $(\text{“temp}_v\text{”}, u)$. Then for each tuple $(\text{“}V\text{”}, v)$, we can query the size of temp_v by operations described in **Sizes of sets** and **Multiple queries**. If the size is not 0, then $T_i(v)$ must be null. Line 15 can be implemented by coping input for different tasks and running tasks in parallel, where it only needs operations shown in **Copies of sets**, **Multiple queries** and **Multiple Tasks** (see Section 32.7.6). According to Lemma 32.8.5, it only needs $O(1)$ parallel time. Line 16 and line 19 only need the operation shown in **Multiple queries**.

Thus, the total parallel time is $O(r)$ where r is the number of iterations (see Definition 32.5.4) of MultiRadiusLCSPT(G, m). For the total space, we stored the sets $V_{T_i(v)}$ for all $i \in [r], v \in V$ and mappings $\text{par}_{T_i(v)}, \text{dep}_{T_i(v)}$ for all $i \in [r], v \in V$. By Lemma 32.5.2, the total space to store all of them is at most $O(r \cdot n \cdot (m/n)^{1/4}) = O(m)$. In the i^{th} round of

the main loop, line 15 may make copies of the set. By Lemma 32.5.2, the input size of each task will be at most $O((m/n)^{1/4} \cdot (m/n)^{1/4})$. Since the there are at most n tasks, the total space needed is at most $O(m)$. □

Lemma 32.8.7. *Let graph $G = (V, E), n = |V|, N = |V| + |E|$ and $m = \Theta(N^\gamma)$ for some arbitrary $\gamma \in [0, 2]$.* MultipleLargeTrees(G, m) *(Algorithm 32.6) can be implemented in $(\gamma, \delta) -$* MPC *model for any constant $\delta \in (0, 1)$. Furthermore, the parallel running time is $O(r)$, where r is the number of iterations (see Definition 32.5.5) of* MultipleLargeTrees(G, m).

Proof. By Lemma 32.8.6, line 3 can be implemented in total space m and $O(r)$ parallel time where r is the number of iterations (see Definition 32.5.4) of MultiRadiusLCSPT(G, m). Line 4 to line 6 can be implemented by the operation described by **Multiple queries**. The implementation of line 7 to line 17 is similar as the implementation of the main loop of Algorithm 32.5 (See Lemma 32.8.6 for details of the implementation). The implementation of line 18 and line 19 only needs the operation described in **Indexing elements in sets** and **Multiple queries**. Line 22 can be implemented by copying input sets for different tasks and running multiple tasks in parallel, where the operations needed are described in **Copies of sets**, **Multiple queries** and **Multiple Tasks** (see Section 32.7.6). Line 24 to line 28 can be implemented by the operations described in **Copies of sets**, **Set membership**, **Indexing elements in sets**, and **Multiple queries**.

The total parallel time of the first loop is $O(r)$ since it has r rounds. The second loop can be done in one round. Thus the parallel time of the second loop is $O(1)$. Then the total parallel time is $O(r)$. Due to Lemma 32.8.6 and Lemma 32.5.6, r is the number of iterations (see Definition 32.5.5) of MultipleLargeTrees(G, m).

We stored all the $V_{T_i(v)}, V_{\widetilde{T}_i(v)}, \mathrm{par}_{T_i(v)}, \mathrm{par}_{\widetilde{T}_i(v)}, \mathrm{dep}_{T_i(v)}, \mathrm{dep}_{\widetilde{T}_i(v)}$ in the system. By Lemma 32.5.3 and Lemma 32.5.2, the total space needed to store them is at most $O(m)$. Furthermore, at any round, the size of all the input copies for multiple tasks is at most $n \cdot (m/n)^{1/4} \cdot (m/n)^{1/4} = O(m)$. Thus, the total space needed is $O(m)$. □

32.8.5 Path Generation and Root Changing

Lemma 32.8.8. *Let* par : $V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*. Let* $n = |V|$*.* FindAncestors(par) *(Algorithm 32.7) can be implemented in* $(\gamma, \delta)-$MPC *model for any* $\gamma \geq \frac{\log n}{\log \log n}$ *and any constant* $\delta \in (0, 1)$*. The parallel running time is* $O(r)$*, where* r *is the number of iterations (see Definition 32.5.6) of* FindAncestors(par)*.*

Proof. The structure of the whole algorithm is the same as the Algorithm 32.2 (see Lemma 32.8.2). All the steps can be done by operation described in **Multiple queries**.

Since the number of rounds needed is r, the parallel time is $O(r)$. For the total space, we need to store all the mappings $g_1, \cdots, g_r$. At the end of the i^{th} round, we need to store mapping h_i. According to Lemma 32.5.7, $r = O(\log n)$ Thus, the total space is $O(rn) = O(n \log n)$. □

Lemma 32.8.9. *Let* par : $V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*. Let* q *be a vertex in* V*, and* $n = |V|$*.* FindPath(par, q) *(Algorithm 32.8) can be implemented in* $(\gamma, \delta) -$ MPC *model for any* $\gamma \geq \frac{\log n}{\log \log n}$ *and any constant* $\delta \in (0, 1)$*. The parallel running time is* $O(r)$*, where* r *is the number of iterations (see Definition 32.5.6) of* FindAncestors(par) *(Algorithm 32.7).*

Proof. By Lemma 32.8.8, FindAncestors(par) can be implemented in $(\gamma, \delta)-$MPC model for $\gamma \geq \frac{\log n}{\log \log n}$ and any constant $\delta \in (0, 1)$. All the other other steps in the algorithm can be done by operation described in **Multiple queries**. Notice that, after each round, we need to do load balancing which can be done by operation described in **Load balance**.

The number of rounds must be smaller than $O(r)$, where r should be the number of iterations of FindAncestors(par) according to Lemma 32.8.8.

We store all the mappings $g_i, \text{dep}_{\text{par}}$ in the system. They need $O(n \log n)$ total space. In the i^{th} round, we only need to additionally store set S_i which has size at most $O(n)$. Thus, the total space needed is at most $O(n \log n)$. □

Lemma 32.8.10. *Let* par : $V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*. Let* q *be a vertex in* V*.* RootChange(par, q) *(Algorithm 32.9) can be implemented in* $(\gamma, \delta) -$ MPC *model for any* $\gamma \geq \frac{\log n}{\log \log n}$ *and any constant* $\delta \in (0, 1)$*. The parallel running time is* $O(r)$*, where* r *is the number of iterations (see Definition 32.5.6) of* FindAncestors(par) *(Algorithm 32.7).*

Proof. By Lemma 32.8.9, FindPath(par, q) can be implemented in $(\gamma, \delta) -$ MPC model. The remaining steps in the procedure can be implemented by the operation described by **Multiple queries**, and has $O(1)$ parallel running time.

The total space needed is the total space needed for FindPath(par, q) plus the space needed to store mapping $h, \widehat{\text{par}}$. Thus the total space needed is $O(n \log n) + O(n) = O(n \log n)$.

The parallel running time is linear in the parallel running time of FindPath(par, q). Then, by Lemma 32.8.9, the parallel running time is $O(r)$ where r is the number of iterations (see Definition 32.5.6) of FindAncestors(par). □

32.8.6 Spanning Forest Algorithm

Lemma 32.8.11. *Let $G_2 = (V_2, E_2)$ be an undirected graph. Let $\widetilde{\text{par}} : V_2 \to V_2$ be a set of parent pointers (See Definition 32.4.2) which satisfies that $\forall v \in V_2$ with $\widetilde{\text{par}}(v) \neq v$, $(v, \widetilde{\text{par}}(v))$ must be in E_2. Let $G_1 = (V_1, E_1)$ be an undirected graph satisfies $V_1 = \{v \in V_2 \mid \widetilde{\text{par}}(v) = v\}, E_1 = \{(u, v) \in V_1 \times V_1 \mid u \neq v, \exists (x, y) \in E_2, \widetilde{\text{par}}^{(\infty)}(x) = u, \widetilde{\text{par}}^{(\infty)}(y) = v\}$. Let $\text{par} : V_1 \to V_1$ be a rooted spanning forest (See Definition 32.5.7) of G_1. Let $f : V_1 \times V_1 \to \{\text{null}\} \cup (V_2 \times V_2)$ satisfy the following property: for $u \neq v \in V_1$, if $\text{part}(u) = v$, then $f(u, v) \in \{(x, y) \in E_2 \mid \widetilde{\text{par}}^{(\infty)}(x) = u, \widetilde{\text{par}}^{(\infty)}(y) = v\}$, and $f(v, u) \in \{(x, y) \in E_2 \mid \widetilde{\text{par}}^{(\infty)}(x) = v, \widetilde{\text{par}}^{(\infty)}(y) = u\}$. Let $n = |V_2|$. Then* ForestExpansion$(\text{par}, \widetilde{\text{par}}, f)$ *(Algorithm 32.10) can be implemented in $(\gamma, \delta) -$ MPC model for any $\gamma \geq \log n / \log \log n$ and any constant $\delta \in (0, 1)$ in parallel running time $O(R)$, where $R = \log(\text{dep}(\widetilde{\text{par}}))$.*

Proof. Due to Lemma 32.8.2, line 3 can be done in $O(R)$ parallel time for $R = \log(\text{dep}(\widetilde{\text{par}}))$. Line 9 corresponds to multiple tasks, we can implement them parallelly by operations described in **Multiple queries**, and **Multiple Tasks** (see Section 32.7.6). By Lemma 32.8.10, the total space needed is at most $O(n \log n)$ and the parallel running time is at most $O(R)$ where $R = \log(\text{dep}(\widetilde{\text{par}}))$. □

Theorem 32.8.12. *Let graph $G = (V, E), n = |V|, N = |V| + |E|$ and $m = \Theta(N^\gamma)$ for some arbitrary $\gamma \in [0, 2]$. Let $r > 0$ be a round parameter.* SpanningForest(G, m, r) *(Algorithm 32.11) can be implemented in $(\gamma, \delta) -$ MPC model for any constant $\delta \in (0, 1)$. Furthermore, the parallel running time is $O(R)$, where R is the total number of iterations (see Definition 32.5.8) of* SpanningForest(G, m, r).

Proof. At the beginning of the algorithm, we just store sets V, E, V_0, E_0 and mapping g_0 in the system.

Consider the i^{th} round of the loop. By Lemma 32.8.7, line 8 can be implemented in total space $\Theta(m)$ and in parallel running time $O(k_i)$ where k_i is the number of iterations (see Definition 32.5.5) of MULTIPLELARGETREES(G_i, m). Line 9 can be implemented by operations described in **Sizes of sets**, **Set membership**, and **Multiple queries**. Line 10 can be implemented by operations described in **Indexing elements in sets**, **Set membership**, and **Multiple queries**. In line 12, to calculate γ_i, we need to query n_i, this can be done by operations described in **Sizes of sets** and **Multiple queries**. In line 14, to compute L_i, we only need operations described in **Set membership** and **Multiple queries**. Line 15 can be implemented by operations shown in **Set membership**, **Indexing elements in sets** and **Multiple queries**. By Lemma 32.8.9, for line 16, there are multiple tasks each can be implemented in $O(|V_{\widetilde{T}_i(v)}| \log |V_{\widetilde{T}_i(v)}|)$ total space, and $O(k_i)$ parallel time. We can schedule these multiple tasks (see Section 32.7.6) such that we can finish them in parallel in $O(k_i)$ parallel time. According to Lemma 32.8.2, for line 17, we can implement it in $O(n_i) = O(n)$ total space, and in $O(k'_i)$ parallel time, where k'_i is the number of iterations (see Definition 32.4.5) of TREECONTRACTION(G'_i, par_i). Line 19 can be done by the operation described in **Multiple queries**. Line 20 can be done by the operation described in **Indexing elements in sets** and **Multiple queries**.

Thus, the parallel time is $O(R)$, where $R = \sum_{i=0}^{r-1}(k_i + k'_i)$. By definition of the total number of iterations (see Definition 32.5.8) of SPANNINGFOREST(G, m, r). R is the total number of iterations of SPANNINGFOREST(G, m, r).

For the space, we store all the sets V, E, V_i, D_i and mappings par_i, h_i in all the rounds.

Notice that $\sum_{i=0}^{r} |V_i| \leq 40|V|$. Thus this part takes only $O(N)$ space. In the i^{th} round, we additionally store all the sets $V_{\widetilde{T}_i(v)}, V'_i, E'_i, L_i$ and all the mappings $\text{par}_{\widetilde{T}_i(v)}, \text{dep}_{\widetilde{T}_i(v)}, l_i, z_i$. The total space for this part is at most $O(m)$. For line 16, it creates multiple tasks. The input of each task is at most $|V_{\widetilde{T}_i(v)}| \leq (m/n_i)^{1/2}$. There are at most n_i tasks, and by Lemma 32.8.9, each task will need space at most $O(|V_{\widetilde{T}_i(v)}| \log |V_{\widetilde{T}_i(v)}|)$. Thus, the space for this part is at most $O(m)$. To conclude, the total space needed is at most $O(m)$.

□

Theorem 32.8.13. *Let graph $G = (V, E), n = |V|, N = |V| + |E|$ and $m = \Theta(N^\gamma)$ for some arbitrary $\gamma \in [0, 2]$. Let $r > 0$ be a round parameter. If* SpanningForest(G, m, r) *(Algorithm 32.11) does not return* FAIL*, then let the output be the input of* Orientate$(\cdot)$ *(Algorithm 32.12), and* Orientate$(\cdot)$ *can be implemented in $(\gamma, \delta) -$* MPC *model for any constant $\delta \in (0, 1)$. Furthermore, the parallel running time is $O(R)$, where R is the total number of iterations (see Definition 32.5.8) of* SpanningForest(G, m, r).

Proof. Line 4 to line 7 can be implemented by operations described in **Multiple queries**. Notice that there is a trick here, if $f_i(u, v) =$ null, we do not need to store the tuple $(\text{“}f_i\text{”}, ((u, v), \text{null}))$ in the system. The total space needed to store all the mappings f_i and all the sets F_i for $i \in \{0\} \cup [r]$ is at most $\sum_{i=0}^{r} |V_i| = O(m)$.

Line 10 and line 11 can be implemented by operations described in **Set membership** and **Multiple queries**.

We now look at the second loop, and focus on round i. Line 12 can be implemented by Lemma 32.8.11. The total space needed is at most $O(|V_i| \cdot (m/|V_i|)^{1/2} \cdot \log(m/|V_i|)) = O(m)$. The parallel running time needed is at most $O(k_i)$, where k_i is the number of iterations (see

Definition 32.5.5) of MULTIPLELARGETREES(G_i, m), G_i is the intermediate graph in the procedure SPANNINGFOREST(G, m, r).

Thus, the parallel running time is $O(R)$, where R is the total number of iterations (see Definition 32.5.8) of SPANNINGFOREST(G, m, r). The total space needed is $O(m)$.

□

Now, we are able to conclude the following theorem for spanning forest problem.

Theorem 32.8.14. *For any $\gamma \in [0, 2]$ and any constant $\delta \in (0, 1)$, there is a randomized $(\gamma, \delta) -$ MPC algorithm (see Algorithm 32.11 and Algorithm 32.12) which can output the rooted spanning forest for any graph $G = (V, E)$ in $O(\min(\log D \cdot \log \frac{1}{\gamma'}, \log n))$ parallel time, where D is the diameter of G, $n = |V|$, $N = |V| + |E|$ and $\gamma' = (1 + \gamma) \log_n \frac{2N}{n^{1/(1+\gamma)}}$. The success probability is at least 0.98. In addition, if the algorithm fails, then it will return* FAIL.

Proof. Algorithm 32.11 outputs all the edges in the spanning forest and all the contraction information. Algorithm 32.12 takes the output of Algorithm 32.11 as its input, and outputs a rooted spanning forest.

The implementation of Algorithm 32.11 and Algorithm 32.12 in MPC model is shown by Theorem 32.8.12 and Theorem 32.8.13 respectively. The correctness of Algorithm 32.11 and Algorithm 32.12 is proved by Corollary 32.5.17 and Theorem 32.5.19 respectively. The parallel time of Algorithm 32.11 and Algorithm 32.12 is proved by Theorem 32.5.21.

□

A byproduct of our spanning forest algorithm is an estimator of the diameter of the graph.

Theorem 32.8.15. *For any $\gamma \in [0,2]$ and any constant $\delta \in (0,1)$, there is a randomized $(\gamma,\delta)-$*MPC *algorithm which can output an diameter estimator D' for any graph $G=(V,E)$ in $O(\min(\log D \cdot \log(1/\gamma'), \log n))$ parallel time such that $D \leq D' \leq D^{O(\log(1/\gamma'))}$, where D is the diameter of G, $n=|V|$, $N=|V|+|E|$ and $\gamma' = (1+\gamma)\log_n \frac{2N}{n^{1/(1+\gamma)}}$. The success probability is at least* 0.98. *In addition, if the algorithm fails, then it will return* FAIL.

Proof. By Theorem 32.8.14, we can find a rooted spanning forest. By Theorem 32.5.19, the depth of that rooted spanning forest is at most $D^{O(\log(1/\gamma'))}$. Then we can implement a doubling algorithm (e.g. Modified Lemma 32.8.8, Algorithm 32.7 without maintaining useless g_l) with log in depth parallel time to output the depth of that spanning forest. □

32.8.7 Lowest Common Ancestor and Multi-Paths Generation

Lemma 32.8.16. *Let* $\text{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*. Let* $Q = \{(u_1, v_1), (u_2, v_2), \cdots, (u_q, v_q)\}$ *be a set of* q *pairs of vertices, and* $\forall i \in [q], u_i \neq v_i$*. Let* $n = |V|, N = n + q$*.* $\text{LCA}(\text{par}, Q)$ *(Algorithm 32.13) can be implemented in* $(\gamma, \delta) - \text{MPC}$ *model for any* $\gamma \geq \log\log N / \log N$ *and any constant* $\delta \in (0, 1)$ *in* $O(\log(\text{dep}(\text{par})))$ *parallel running time.*

Proof. By Lemma 32.8.8, line 3 can be implemented in space $O(N \log N)$ and $O(\log(\text{dep}(\text{par})))$ parallel running time. It is easy to see that all the other steps in the procedure can be done by the operations shown in **Multiple queries**.

Thus, the total space needed is $O(N \log N)$ and the parallel running time is $O(\log(\text{dep}(\text{par})))$.

□

Lemma 32.8.17. *Let* $\text{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*. Let* $Q = \{(u_1, v_1), (u_2, v_2), \cdots, (u_q, v_q)\} \subseteq V \times V$ *satisfy* $\forall j \in [q]$*,* v_j *is an ancestor (See Definition 32.6.1) of* u_j *in* par*. Let* $n = |V|, N = n + q$*.* $\textsc{MultiPath}(\text{par}, Q)$ *(Algorithm 32.14) can be implemented in* $(\gamma, \delta) - \text{MPC}$ *model for any* γ *with* $N \log N + \sum_{i=1}^{q}(\text{dep}_{\text{par}}(u_i) - \text{dep}_{\text{par}}(v_i) + 1) = O(N^{\gamma})$ *and any constant* $\delta \in (0, 1)$ *in* $O(\text{dep}(\text{par}))$ *parallel running time.*

Proof. By Lemma 32.8.8, line 3 can be implemented in space $O(N \log N)$ and $O(\log(\text{dep}(\text{par})))$ parallel running time. It is easy to see that all the other steps in the procedure can be done by the operations shown in **Multiple queries**. Notice that after each round, we need to do load balancing (see **Load balance**) to make each machine have large enough available local

memory. The total space needed is to store all the pathes and the output of line 3. Notice that in round i, we do not need to keep $S_j^{(i')}$ for $i' < i-1$, thus, the space to keep $S_j^{(i)}$ for all $j \in [q]$ only needs $O(\sum_{j=1}^{q}(\mathrm{dep}_{\mathrm{par}}(u_j) - \mathrm{dep}_{\mathrm{par}}(v_j) + 1))$ space.

Thus, the total space needed is at most $O(N \log N + \sum_{i=1}^{q}(\mathrm{dep}_{\mathrm{par}}(u_i) - \mathrm{dep}_{\mathrm{par}}(v_i) + 1)) = O(N^{\gamma})$. The parallel running time is then $O(\mathrm{dep}(\mathrm{par}))$. □

32.8.8 Leaf Sampling

Lemma 32.8.18. *Let* $\mathrm{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*, and* par *has a unique root. Let* $n = |V|$*. Let* δ *be an arbitrary constant in* $(0, 1)$*, and let* $m = \lceil n^\delta \rceil$*. Then* LeafSampling$(\mathrm{par}, m, \delta)$ *(Algorithm 32.15) can be implemented in* $(\gamma, \delta) - \mathrm{MPC}$ *model for any* $\gamma \geq \log\log n / \log n$*. Furthermore, with probability at least* $1 - 1/(100m^{5/\delta})$*, the parallel running time is at most* $O(\log \mathrm{dep}(\mathrm{par}))$*.*

Proof. To implement line 4, for each $v \in V$, we can add $\mathrm{part}(v)$ to a temporary set X. Then each v can check whether v is a leaf by checking whether v is in X, and this can be done by the operations shown in **Set membership** and **Multiple queries**.

To implement line 5, for each $v \in V$, we can add v to the set $\mathrm{child}_{\mathrm{par}}(\mathrm{part}(v))$. Then rank can be computed by the operations shown in **Indexing elements in sets** and **Multiple queries**. For line 6, we can implement it on a single machine, since a single machine has local memory $\Theta(m)$. For line 7 to line 9, for each $x \in L$, we add x into S with probability p, where p can be computed by querying the size of L (see **Sizes of sets** and **Multiple queries**). Line 10 can be implemented by operation described in **Indexing elements in sets**, **Set membership**, and **Multiple queries**. By Lemma 32.8.2, line 11 can be implemented in total space $O(N \log N)$ and $O(\log \mathrm{dep}(\mathrm{par}))$ parallel time. By Property 3 of Lemma 32.6.5, with probability at least $1 - 1/(100m^{5/\delta})$, $|S|^2 = O(m)$. Thus, Q can be stored on a single machine. By Lemma 32.8.16, line 15 can be implemented in total space $O(n \log n + |Q|) = O(n \log n)$ and in $O(\log \mathrm{dep}(\mathrm{par}))$ parallel time. By Lemma 32.8.8, line 17 can be implemented in total space $O(n \log n)$ and in $O(\log \mathrm{dep}(\mathrm{par}))$ parallel time. Then line 18 to line 22 can be implemented on a single machine.

Thus, the total space needed is at most $O(n \log n)$. The parallel time is at most $O(\log \mathrm{dep}(\mathrm{par}))$ $\square$

32.8.9 DFS Sequence

Lemma 32.8.19. *Let* $\mathrm{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*, and* par *has a unique root. Let* $n = |V|$*. Let* δ *be an arbitrary constant in* $(0, 1)$*, and let* $m = \lceil n^{\delta} \rceil$*.* SubDFS$(\mathrm{par}, m, \delta)$ *(Algorithm 32.16) can be implemented in* $(\gamma, \delta)-$MPC *model for any* $\gamma \geq \log\log n / \log n$*. Furthermore, with probability at least* $1 - 1/(100m^{5/\delta})$*, the parallel running time is at most* $O(\log \mathrm{dep}(\mathrm{par}))$*.*

Proof. By Lemma 32.8.18, line 5 can be implemented in total space $O(n \log n)$ and with probability at least $1-1/(100m^{5/\delta})$ has parallel running time $O(\log \mathrm{dep}(\mathrm{par}))$. By Lemma 32.8.16, line 7 can be implemented in total space $O(n \log n)$ and in parallel running time $O(\log \mathrm{dep}(\mathrm{par}))$. Line 9 can be implemented by operation shown in **Multiple queries**. By Lemma 32.8.17, since all the pathes are disjoint (except the first path and the last path intersecting on the root) and V has n vertices, line 10 can be implemented in $O(n \log n)$ total space and in $O(\log \mathrm{dep}(\mathrm{par}))$ parallel running time. Loop in line 13 and Loop in line 16 can be implemented in parallel, and can be implemented by operations shown in **Indexing elements in sets** and **Multiple queries**. Line 20 can be implemented by operations shown in **Indexing elements in sets** and **Multiple queries**. Now we describe the implementation of line 21. Firstly, we can standardize (see **Sequence standardizing**) the sequence A'. For each tuple $(\text{“}A'\text{”}, (j, u))$, create a tuple $(\text{“}temp_u\text{”}, j)$. Thus, “$temp_u$” is a set which contains all the positions that u appeared. For each tuple $(\text{“}temp_u\text{”}, j)$, we query (see **Multiple queries**) the index i (see **Indexing elements in sets**) of j in set $(\text{“}temp_u\text{”}, j)$, and create a tuple $(\text{“pos”}, ((u, i), j))$. Thus, the desired mapping pos is stored in the system. The loop in line 24 is implemented in parallel. Line 25 can be implemented by the operations shown

in **Set membership** and **Multiple queries**. Line 26 to line 28 can be implemented by the operation shown in **Multiple queries**. Finally, line 30 can be implemented by **Multiple queries** and **Sequence duplicating**.

The total space used in the procedure is at most $O(n \log n)$. The parallel running time is $O(\log \operatorname{dep}(\text{par}))$. □

Theorem 32.8.20. *Let* $\text{par} : V \to V$ *be a set of parent pointers (See Definition 32.4.2) on a vertex set* V*, and* par *has a unique root. Let* $n = |V|, m = n^{\delta}$ *for some arbitrary constant* $\delta \in (0, 1)$*.* $\text{DFS}(\text{par}, m)$ *(Algorithm 32.17) can be implemented in* $(\gamma, \delta) - \text{MPC}$ *model for any* $\gamma \geq \log \log n / \log n$*. With probability at least* 0.99*, the parallel running time is* $O(\log(\operatorname{dep}(\text{par})))$.

Proof. By Lemma 32.8.19, line 5 can be implemented in total space $O(n \log n)$. With probability at least $1 - 1/(100n^5)$, the parallel running time is $O(\log(\operatorname{dep}(\text{par})))$. Line 8 to line 10 can be implemented by operations shown in **Set membership** and **Multiple queries**. By Lemma 32.8.2, line 11 can be implemented in $O(n)$ total space, and $O(\log \operatorname{dep}(\text{par}))$ parallel running time. The loop in line 14 contains multiple tasks (see Section 32.7.6 **Multiple Tasks**), thus we can implement those tasks in parallel. By Lemma 32.8.19, line 17 can be implemented in total space $O(|V_i'(v)| \log |V_i'(v)|)$. Furthermore, with probability at least $1 - 1/(100n^5)$, the parallel running time is $O(\log(\operatorname{dep}(\text{par})))$. Thus, the total space needed for those tasks is at most $O(n \log n)$. Line 19 can be implemented by operations shown in **Indexing elements in sets**, **Sequence insertion** and **Multiple queries**.

Thus, the total space needed is $O(n \log n)$. By taking union bound over all the task SubDFS, with probability at least 0.99, the parallel running time is $O(\log \operatorname{dep}(\text{par}))$. □

Now we are able to conclude the following theorem.

Theorem 32.8.21. *For any $\gamma \in [\beta, 2]$ and any constant $\delta \in (0, 1)$, there is a randomized $(\gamma, \delta)-$*MPC *algorithm (Algorithm 32.17) which can output a Depth-First-Search sequence for any tree graph $G = (V, E)$ in $O(\min(\log D \cdot \log(1/\gamma'), \log n))$ parallel time, where $n = |V|$, $\beta = \Theta(\log \log n / \log n)$, D is the diameter of G, and $\gamma' = \gamma + \Theta(1/\log n)$. The success probability is at least* 0.98. *In addition, if the algorithm fails, then it will return* FAIL.

Proof. Firstly, by Theorem 32.8.14, we can find a rooted tree. Algorithm 32.17 can output the DFS sequence for a rooted tree.

The implementation and parallel time of Algorithm 32.17 is shown by Theorem 32.8.20. The correctness of Algorithm 32.17 is proved by Theorem 32.6.12. The success probability of Algorithm 32.17 is proved by Theorem 32.6.14. □

32.8.10 Range Minimum Query

Lemma 32.8.22. *Let $A = (a_1, a_2, \cdots, a_n)$ be a sequence of numbers. Let δ be an arbitrary constant in $(0, 1)$.* SparseTable$^+(a_1, a_2, \cdots, a_n, \delta)$ *(Algorithm 32.18) can be implemented in $(0, \delta)-$*MPC *model with $O(1)$ parallel running time.*

Proof. Let A be the sequence $(a_1, a_2, \cdots, a_n)$. The algorithm takes $O(1/\delta)$ rounds. m is the local space of a machine. There are $\Theta(n/m)$ machines each holds a consecutive $\Theta(m)$ elements of sequence A. Now consider the round l. Machine $j \in \{0\} \cup [\lceil n/m \rceil]$ needs to compute $\widehat{f}_{j\cdot m+1,l}, \widehat{f}_{j\cdot m+2,l}, \cdots, \widehat{f}_{j\cdot m+m-1,l}$. The number of queries machine j made in line 8 and line 11 is at most $\sum_{t=1}^{\lceil 1/\delta \rceil} |S_t| + 2m \leq O(m/\delta) = O(m)$. Thus, there are total $O(n)$ queries. These queries can be answered simultaneously by operation shown in **Multiple queries**.

Thus, the total space needed is $O(n)$, and the parallel running time is $O(1)$. □

Lemma 32.8.23. *Let $a_1, a_2, \cdots, a_n$ be a sequence of numbers. Let δ be an arbitrary constant in $(0, 1)$.* SparseTable$(a_1, a_2, \cdots, a_n, \delta)$ *(Algorithm 32.19) can be implemented in $(\gamma, \delta)-$*MPC *model for any $\gamma \geq \log\log n / \log n$ in $O(1)$ parallel time.*

Proof. By Lemma 32.8.22, line 4 can be implemented in $O(n)$ total space and $O(1)$ parallel time. The loop in line 15 is similar to Algorithm 32.18. Each machine j needs to compute $f_{j\cdot m+1,t}, \cdots, f_{j\cdot m+m-1,t}$ for all $t \in [\lceil \log n \rceil] \cup \{0\}$. The difference from Algorithm 32.18 is that, it can compute for all t at the same time since it only depends on the value of $\widehat{f}$. The number of queries made by each machine is $O(m \log n)$. Thus, the total number of queries is at most $O(n \log n)$. These queries can be answered simultaneously by operation shown in **Multiple queries**.

Thus, the total space needed is $O(n \log n)$, and the parallel running time is $O(1)$. $\square$

32.9 Minimum Spanning Forest

In this section, we discuss how to apply our connectivity/spanning forest algorithm to the Minimum Spanning Forest (MSF) and Bottleneck Spanning Forest (BSF) problem.

The input of MSF/BSF problem is an undirected graph $G = (V, E)$ together with a weight function $w : E \to \mathbb{Z}$, where E contains m edges $e_1, e_2, \cdots, e_m$ with $w(e_1) \leq w(e_2) \leq \cdots \leq w(e_m)$. The goal of MSF is to output a spanning forest such that the sum of weights of the edges in the forest is minimized. The goal of BSF is to output a spanning forest such that the maximum weight of the edges in the forest is minimized. D is the diameter of the minimum spanning forest. If there are multiple choices of the minimum spanning forest, then let D be the minimum diameter among all the minimum spanning forests.

For simplicity, in all of our proofs, we only discuss the case when all the edges have different weights, i.e. $w(e_1) < w(e_2) < \cdots < w(e_m)$. In this case, the minimum spanning forest is unique. It is easy to extend our algorithms to the case when there are edges with the same weight. We omit the proof for this fact.

Firstly, we show that D is an upper bound of the diameter of G' where the vertex set of G' is the vertex set of G, and the edge set of G' is $\{e_1, e_2, \cdots, e_i\}$ for some arbitrary $i \in [m]$.

Lemma 32.9.1. *Given a graph $G = (V, E)$ for $E = \{e_1, e_2, \cdots, e_m\}$ together with a weight function w which satisfies $w(e_1) < w(e_2) < \cdots < w(e_m)$, then the diameter of $G' = (V, E')$ is at most D, where D is the diameter of the minimum spanning forest of G, and E' only contains the first i edges of E, i.e. $e_1, e_2, \cdots, e_i$ for some arbitrary $i \in [m]$.*

Proof. The proof follows by Kruskal's algorithm directly. □

Our algorithms is based on the following simple but useful Lemma.

Lemma 32.9.2. *Given a graph $G = (V, E)$ for $E = \{e_1, e_2, \cdots, e_m\}$ together with a weight function w which satisfies $w(e_1) \leq w(e_2) \leq \cdots \leq w(e_m)$, $\forall 1 \leq i < j \leq m$, an edge e from $\{e_i, e_{i+1}, \cdots, e_j\}$ is in the minimum spanning forest of G if and only if e' from $\{e'_i, e'_{i+1}, \cdots, e'_j\}$ is in the minimum spanning forest of G', where the vertices of G' is obtained by contracting all the edges $e_1, e_2, \cdots, e_{i-1}$ of G, and $e', e'_i, e'_{i+1}, \cdots, e'_j$ are the edges (or vertices) in G' which corresponds to the edges $e, e_i, e_{i+1}, \cdots, e_j$ before contraction.*

Proof. The proof follows by Kruskal's algorithm directly. □

A natural way to apply Lemma 32.9.2 to parallel minimum spanning forest algorithm is that we can divide the edges into several groups, and recursively solve the minimum spanning forest for each group of edges. More precisely, suppose we have total space $\Theta(km)$, we can divide E into k groups $E_1, E_2, \cdots, E_k$, where $E_i = \{e_{(i-1)\cdot m/k+1}, e_{(i-1)\cdot m/k+2}, \cdots, e_{i\cdot m/k}\}$. We can compute graph $G_1, G_2, \cdots, G_k$ where the vertices of G_i is obtained by contracting all the edges from e_1 to $e_{(i-1)\cdot m/k}$, the edges of G_i are corresponding to the edges in E_i. Then by Lemma 32.9.2, we can obtain the whole minimum spanning forest by solving these k size $O(m/k)$ minimum spanning forest problems. For each sub-problem, we can assign it $\Theta(m)$ working space, thus each sub-problem still has $\Theta(k)$ factor more total space. Therefore, we can recursively apply the above argument.

Theorem 32.9.3. *For any $\gamma \in [0, 2]$ and any constant $\delta \in (0, 1)$, there is a randomized $(\gamma, \delta) - \mathrm{MPC}$ algorithm which can output a minimum spanning forest for any weighted graph $G = (V, E)$ with weights $w : E \to \mathbb{Z}$ in $O(\min(\log D \cdot \log(1/\gamma'), \log n) \cdot 1/\gamma')$ parallel time,*

where $n = |V|$, $\forall e \in E, |w(e)| \leq \text{poly}(n)$, D *is the diameter of a minimum spanning forest of* G, *and* $\gamma' = \gamma/2 + \Theta(1/\log n)$. *The success probability is at least* 0.98. *In addition, if the algorithm fails, then it will return* FAIL.

Proof. Let $n = |V|, m = |E|$. Let $E = \{e_1, \cdots, e_m\}$ with $w(e_1) \leq w(e_2) \leq \cdots \leq w(e_m)$. The total space in the system is $\Theta(m^{1+\gamma})$. Let $k = \Theta(m^{\gamma/2})$. By our previous discussion, we can divide E into k groups $E_1, E_2, \cdots, E_k$, where $E_i = \{e_{(i-1)\cdot m/k+1}, e_{(i-1)\cdot m/k+2}, \cdots, e_{i\cdot m/k}\}$. By Lemma 32.9.1 and Theorem 32.8.4, we can use $O(\min(\log D \cdot \log(1/\gamma'), \log n))$ parallel time and $\Theta(km^{1+\gamma/2})$ total space to compute graph $G_1, G_2, \cdots, G_k$ where the vertices of G_i is obtained by contracting all the edges from e_1 to $e_{(i-1)\cdot m/k}$, the edges of G_i are corresponding to the edges in E_i after contraction.

By Lemma 32.9.2, it suffices to recursively solve the minimum spanning forest problem for each group G_i. Since each time, we split the edges into k groups, the recursion will have at most $O(1/\gamma')$ levels. At the end of the recursion, we are able to determine for every edge e whether e is in the minimum spanning forest.

Now let us consider the success probability. Although Theorem 32.8.4 is a randomized algorithm, the parallel time is always bounded by $\min(\log D \cdot \log(1/\gamma'), \log n)$. If we repeat the algorithm until it succeeds, the expectation of number of trials is a constant. Furthermore, for each level of the recursion, we can regard the graphs in all the tasks composed one large graph. Thus, in real implementation, in each level of the recursion, we will only invoke one connectivity procedure. Thus in expectation, the total parallel time is $O(\min(\log D \cdot \log(1/\gamma'), \log n) \cdot 1/\gamma')$. By applying Markov's inequality, we complete the proof. □

In the following theorem, we show that Lemma 32.9.2 can also be applied in approximate minimum spanning forest problem.

Theorem 32.9.4. *For any $\gamma \in [\beta, 2]$ and any constant $\delta \in (0, 1)$, there is a randomized $(\gamma, \delta) -$ MPC algorithm which can output a $(1+\epsilon)$ approximate minimum spanning forest for any weighted graph $G = (V, E)$ with weights $w : E \to \mathbb{Z}_{\geq 0}$ in $O(\min(\log D \cdot \log(1/\gamma'), \log n))$ parallel time, where $n = |V|$, $N = |V| + |E|$, $\beta = \Theta(\log(\epsilon^{-1} \log n)/\log n)$, $\forall e \in E, |w(e)| \leq \text{poly}(n)$, D is the diameter of a minimum spanning forest of G, and $\gamma' = (1 + \gamma - \beta) \log_n \frac{2N}{n^{1/(1+\gamma-\beta)}}$. The success probability is at least 0.98. In addition, if the algorithm fails, then it will return* FAIL.

Proof. For each edge $e \in E$, we can round $w(e)$ to $w'(e)$ such that $w'(e) = 0$ when $w(e) = 0$, and $w'(e) = (1+\epsilon)^i$ when $w(e) \neq 0$, and i is the smallest integer such that $w(e) \leq (1+\epsilon)^i$.

Since $|w(e)| \leq \text{poly}(n)$ for all $e \in E$, there are only $k = O(\log(n)/\epsilon)$ different values of $w'(e)$. We can divide E into k groups, where the i^{th} group E_i contains all edges with the i^{th} largest weight in w'. By Lemma 32.9.1 and Theorem 32.8.4, we can use $O(\min(\log D \cdot \log(1/\gamma'), \log n))$ parallel time and $\Theta(kN^{1+\gamma-\beta}) = \Theta(N^{1+\gamma})$ total space to compute graph $G_1, G_2, \cdots, G_k$ where the vertices of G_i is obtained by contracting all the edges from E_1 to E_{i-1}, the edges of G_i are corresponding to the edges in E_i after contraction.

Then, for each G_i, since all the edges have the same w' weight, any spanning forest of G_i is a minimum spanning forest of G_i. By Theorem 32.8.14, we can use $O(\min(\log D \cdot \log(1/\gamma'), \log n))$ parallel time and $\Theta(kN^{1+\gamma-\beta}) = \Theta(N^{1+\gamma})$ total space to compute the spanning forest for each graph $G_1, G_2, \cdot, G_k$. By Lemma 32.9.2, the union of all the minimum spanning forest with respect to w' must be the minimum spanning forest of G with respect

to w'. Since all the weights w are nonnegative integers, w' is a $(1+\epsilon)$ approximation to w. Therefore, our output minimum spanning forest with respect to w' is a $(1+\epsilon)$ approximation to the minimum spanning forest with respect to w.

For the success probability, we can apply the similar argument made in the proof of Theorem 32.9.3 to prove that the success probability is at least 0.98. □

In the following, we show that if we only need to find the largest edge in the minimum spanning tree, then we are able to get a better parallel time. It is an another application of our

Theorem 32.9.5. *For any $\gamma \in [0,2]$ and any constant $\delta \in (0,1)$, there is a randomized $(\gamma,\delta)-$*MPC *algorithm which can output a bottleneck spanning forest for any weighted graph $G=(V,E)$ with weights $w : E \to \mathbb{Z}$ in $O(\min(\log D \cdot \log(1/\gamma'), \log n) \cdot \log(1/\gamma'))$ parallel time, where $n = |V|$, $\forall e \in E, |w(e)| \leq \text{poly}(n)$, D is the diameter of a minimum spanning forest of G, and $\gamma' = \gamma/2 + \Theta(1/\log n)$. The success probability is at least 0.98. In addition, if the algorithm fails, then it will return* FAIL.

Proof. Let $n = |V|, m = |E|$. Let $E = \{e_1, \cdots, e_m\}$ with $w(e_1) \leq w(e_2) \leq \cdots \leq w(e_m)$. The total space in the system is $\Theta(m^{1+\gamma})$. Let $k = \Theta(m^{\gamma/2})$. By our previous discussion, we can divide E into k groups $E_1, E_2, \cdots, E_k$, where $E_i = \{e_{(i-1)\cdot m/k+1}, e_{(i-1)\cdot m/k+2}, \cdots, e_{i\cdot m/k}\}$. By Lemma 32.9.1 and Theorem 32.8.4, we can use $O(\min(\log D \cdot \log(1/\gamma'), \log n))$ parallel time and $\Theta(km^{1+\gamma/2})$ total space to compute graph $G_1, G_2, \cdots, G_k$ where the vertices of G_i is obtained by contracting all the edges from e_1 to $e_{(i-1)\cdot m/k}$, the edges of G_i are corresponding to the edges in E_i after contraction.

By Lemma 32.9.2, the edge with largest weight must be in the group E_i for some i with $G_{i+1} = G_{i+2}$. Thus, we reduce the problem size to m/k. By Remark 32.1.2, we can finish the recursion in $O(\log(1/\gamma'))$ phases.

Suppose the bottleneck is e_i, then by Theorem 32.8.14, we can find a spanning forest by only using edges from $\{e_1, \cdots, e_i\}$ in $O(\min(\log D \cdot \log(1/\gamma'), \log n))$ parallel time and in $\Theta(m^{1+\gamma/2})$ total space. Thus, the resulting spanning forest is a bottleneck spanning forest.

For the success probability, we can apply the similar argument made in the proof of Theorem 32.9.3 to prove that the success probability is at least 0.98. □

32.10 Directed Reachability vs. Boolean Matrix Multiplication

In this section, we discuss the directed graph reachability problem which is a directed graph problem highly related to the undirected graph connectivity. In the all-pair directed graph reachability problem, we are given a directed graph $G = (V, E)$, the goal is to answer for every pair $(u, v) \in V \times V$ whether there is a directed path from u to v. There is a simple standard way to reduce Boolean Matrix Multiplication to all-pair directed graph reachability problem. In the Boolean Matrix Multiplication problem, we are given two boolean matrices $A, B \in \{0,1\}^{n \times n}$, the goal is to compute $C = A \cdot B$, where $\forall i, j \in [n]$, $C_{i,j} = \bigvee_{k \in [n]} A_{i,k} \wedge B_{k,j}$. The reduction is as the following. We create $3n$ vertices $u_1, u_2, \cdots, u_n, v_1, v_2, \cdots, v_n, w_1, w_2, \cdots, w_n$. For every $i, j \in [n]$, if $A_{i,j} = 1$, then we add an edge from u_i to v_j, and if $B_{i,j} = 1$, then we add an edge from v_i to w_j. Thus, $C_{i,j} = 1$ is equivalent to there is a path from u_i to w_j. Thus, if we can solve all-pair directed graph reachability problem in $O(T)$ sequential time, then we can solve Boolean Matrix Multiplication in $O(T)$ time. For the current status of sequential running time of Boolean Matrix Multiplication problem, we refer readers to [LG14] and the references therein.

Now, consider the multi-query directed graph reachability problem. In this problem, we are given a directed graph $G = (V, E)$ together with $|V| + |E|$ queries where each query queries the reachability from vertex u to vertex v. The goal is to answer all these queries. A similar problem in the undirected graph is called multi-query undirected graph connectivity problem. In this problem, we are given an undirected graph $G = (V, E)$ together with $|V| + |E|$ queries where each query queries the connectivity between vertex u and vertex v.

According to Theorem 32.8.4 and Lemma 32.7.4, there is a polynomial local running time fully scalable $\sim \log D$ parallel time $(0, \delta) -$ MPC algorithm for multi-query undirected

graph connectivity problem. Here polynomial local running time means that there is a constant $c > 0$ (independent from δ) such that every machine in one round can only have $O((n^{\delta})^{c})$ local computation.

For multi-query directed graph reachability problem, we show that if there is a polynomial local running time fully scalable $(\gamma, \delta) - \text{MPC}$ algorithm which can solve multi-query reachability problem in $O(n^{\alpha})$ parallel time, then we can solve all-pair directed graph reachability problem in $O(n^2 \cdot n^{2\gamma+\alpha+\epsilon})$ sequential running time for any arbitrarily small constant $\epsilon > 0$. Especially, if the algorithm is in $(0, \delta) - \text{MPC}$ model, and the parallel time is $n^{o(1)}$, then we will have an $O(n^{2+\epsilon+o(1)})$ sequential running time algorithm for Boolean Matrix Multiplication which implies a break through in this field.

Suppose we have a such MPC algorithm. Let the input size be $\Theta(m)$, i.e. the number of edges is $\Theta(m)$, and the number of queries is also $\Theta(m)$. Then the total space is $\Theta(m^{1+\gamma})$. Let $\delta = \epsilon/(c-2)$. Then the number of machines is $\Theta(m^{1+\gamma-\delta})$. Now we just simulate this $(\gamma, \delta) - \text{MPC}$ algorithm sequentially, the total running time is $O(m^{1+\gamma-\delta} \cdot m^{c\delta} \cdot n^{\alpha}) = O(m \cdot n^{2\gamma+\epsilon+\alpha})$. To answer reachability for all pairs, we need total $O(n^2 \cdot m \cdot n^{2\gamma+\epsilon+\alpha}/m) = O(n^2 \cdot n^{2\gamma+\alpha+\epsilon})$ time. Therefore, we can use this algorithm to solve Boolean Matrix Multiplication in $O(n^2 \cdot n^{2\gamma+\alpha+\epsilon})$ time.

Theorem 32.10.1. *If there is a polynomial local running time fully scalable $(\gamma, \delta) - \text{MPC}$ algorithm which can answer $|V| + |E|$ pairs of reachability queries simultaneously for any directed graph $G = (V, E)$ in $O(|V|^{\alpha})$ parallel time, then there is a sequential algorithm which can compute the multiplication of two $n \times n$ boolean matrices in $O(n^2 \cdot n^{2\gamma+\alpha+\epsilon})$ time, where $\epsilon > 0$ is a constant which can be arbitrarily small.*

Proof. See above discussions. □

32.11 Discussion on a Previous Conjectured Fast Algorithm

In this section, we discuss the hard example for the algorithm described by [RMCS13]. In [RMCS13], they conjectured that their Hash-to-Min connectivity algorithm can finish in $O(\log D)$ rounds. The description of their algorithm is as the following:

1. The input graph is $G = (V, E)$.
2. For each vertex $v \in V$, initialize a set $S_v^{(0)} = v$.
3. in round i:
   (a) Each vertex v find $u \in S_v^{(i-1)}$ which has the minimum label, i.e. $u = \min_{x \in S_v^{(i-1)}} x$.
   (b) v sends u the all the vertices in $S_v^{(i-1)}$.
   (c) v sends every $x \in S_v^{((i-1))} \setminus \{u\}$ the vertex u.
   (d) Let $S_v^{(i)}$ be $\{v\}$ union the set of all the vertices received.
   (e) If for all v, $S_v^{(i)}$ is the same as $S_v^{(i-1)}$, then finish the procedure.

The above procedure can be seen as the modification of the graph: in each round, all the vertices together create a new graph. For each vertex v, let u be the neighbor of v with the minimum label, and if x is a neighbor of v, then add an edge between x and u in the new graph. So in each round, each vertex just communicates with its neighbors to update the new minimum neighbor it learned. At the end of the algorithm, it is obvious that the minimum vertex in each component will have all the other vertices in that component, and for each non minimum vertex, it will have the minimum vertex in the same component.

A hard example for this algorithm is shown by Figure 32.3. The example is a thin and tall grid graph with a vertex connected to all the vertices in the first column. The total number of vertices is n. The grid graph has $D = \frac{1}{2}\log n$ columns and n/D rows. We index each column from left to right by 1 to D. We index each row from top to down by 1 to n/D. The single large degree vertex has label 0. The i^{th} row has the vertices with label $(i-1)\cdot D+1$ to $i\cdot D$ from the first column to the D^{th} column. We claim that if vertex v is the i^{th} row and j^{th} column, then before round k for $2^k < i, k < j$, the neighbors of v will only in column $j-1$, column j and column $j+1$. Furthermore, the minimum neighbor of v in column $j-1$ will be $v-(2^{k-1}-1)\cdot D-1$. The minimum neighbor of v in column j will be $v-2^{k-1}\cdot D$. The minimum neighbor of v in column $j+1$ will be $v-D\cdot(2^{k-1}-1)+1$. This claim is true when $k=1$. Then by induction, we can prove the claim. Thus, it will take at least $\Theta(D)$ rounds to finish the procedure where $D=\Theta(\log n)$.

If we randomly label the vertices at the beginning, then consider the case we copy that hard structure at least n^{n+2} times, then with high probability, there is a component which has the labels with the order as the same as described above. In this case, the procedure needs $\Omega(\log\log N)$ rounds, where $N=n^{n+3}$ is the total number of the vertices.

Also notice that, even we give more total space to this algorithm, this algorithm will not preform better. In our connectivity algorithm, if we have $\Omega(n^{1+\epsilon})$ total space for some arbitrary constant $\epsilon > 0$, then our parallel running time is $O(\log D)$.

32.12 Alternative Approach for Leader Selection

In this section, we show that there is a different way to select leaders (see Section 32.4.2). The number of leaders selected by this approach will depend on the sum of inverse degrees of all the vertices. Let us first introduce the concept of *Min Parent Forest*.

32.12.1 Min Parent Forest

Let $G = (V, E)$ be an undirected graph where V denotes the vertex set of G, and E denotes the edge set of G. Each vertex $v \in V$ has a weight $w(v) \in \mathbb{R}$, and it also has a unique label from $\mathbb{Z}$. For convenience, for each vertex $v \in V$, we also use v to denote its label. Let $\Gamma_G(v)$ denote the set of neighbors of v, i.e. $\Gamma_G(v) = \{u \in V \mid (u, v) \in E\}$. If G is clear in the context, we just use $\Gamma(v)$ to denote $\Gamma_G(v)$. The size of $\Gamma(v)$, $|\Gamma(v)|$, is called the degree of v. Let $f_{G,w} : V \to V$ be the "min-weight-parent" function defined as the following:

1. If $w(v) = \min_{u \in \Gamma(v) \cup \{v\}} w(u)$, then $f_{G,w}(v) = v$.
2. Otherwise, let $u^* \in \Gamma(v)$ be the vertex which has the smallest weight, i.e. $w(u^*) = \min_{u \in \Gamma(v)} w(u)$. If there is more than one choice of u^*, let u^* be the one with the smallest label. And $f_{G,w}(v)$ is defined to be u^*.

We call $(V, f_{G,w})$ the *min-parent-forest* of graph G with vertex weights w. We can then define i-step "min-weight-parent" function. For $v \in V$, we define $f^{(0)}_{G,w}(v) = v$. For $i \in \mathbb{Z}_{>0}$, we can define $f^{(i)}_{G,w}$ as the following:

$$\forall v \in V, f^{(i)}_{G,w}(v) = f_{G,w}(f^{(i-1)}_{G,w}(v)).$$

In the following, we define the concept of roots in the *min-parent-forest*.

Definition 32.12.1 (Roots in the forest)**.** Let $v \in V$, and let $(V, f_{G,w})$ be the *min-parent-forest* of graph $G = (V, E)$ with vertex weights w. If $f_{G,w}(v) = v$, then v is a root in the forest $(V, f_{G,w})$.

The depth of a vertex v is defined as the distance on the tree between v and the corresponding root in the forest.

Definition 32.12.2 (The depth of v)**.** Let $v \in V$, and let $(V, f_{G,w})$ be the *min-parent-forest* of graph $G = (V, E)$ with vertex weights w. The depth of v in the forest $(V, f_{G,w})$ is the smallest $i \in \mathbb{Z}_{\geq 0}$ such that $f_{G,w}^{(i)}(v) = f_{G,w}^{(i+1)}(v)$. We use $\mathrm{dep}_{G,w}(v)$ to denote the depth of v in $(V, f_{G,w})$. We call $f_{G,w}^{(\mathrm{dep}_{G,w}(v))}(v)$ the root of v. For the simplicity of the notation, we also use $f_{G,w}^{(\infty)}(v)$ to denote the root of v.

The above definition is well defined since if $f_{G,w}^{(i+1)}(v) \neq f_{G,w}^{(i)}(v)$ then $w(f_{G,w}^{(i+1)}(v))$ should be strictly smaller than $w(f_{G,w}^{(i)}(v))$ by the definition of $f_{G,w}$ and $f_{G,w}^{(j)}$ for all $j \in \mathbb{Z}_{\geq 0}$. Therefore, there must exist i such that $f_{G,w}^{(i)}(v) = f_{G,w}^{(i+1)}(v)$.

The depth of the forest is the largest depth among all the vertices.

Definition 32.12.3 (The depth of the *min-parent-forest*)**.** The depth $\mathrm{dep}(G, w)$ of the forest $(V, f_{G,w})$ is defined as:

$$\mathrm{dep}(G, w) = \max_{v \in V} \mathrm{dep}_{G,w}(v).$$

If the weights w of vertices of G are some i.i.d. random variables, then with high probability, the depth of $(V, f_{G,w})$ is only $O(\log |V|)$. Precisely, we have the following Lemma.

Lemma 32.12.1 (The depth of the random *min-parent-forest*)**.** *Let $G = (V, E)$ be an undirected graph with n vertices where $V = \{v_1, v_2, \cdots, v_n\}$, and the labels satisfies $v_1 < v_2 < \cdots < v_n$. Let $w(v_1), w(v_2), \cdots, w(v_n)$ be n i.i.d. random variables drawn uniformly from $[N]$. If $N > n^2/\delta$ for some $\delta \in (0, 1)$, then for any $t \geq 60 \log n$,*

$$\Pr_{w \sim [N]^n} (\mathrm{dep}(G, w) \leq t) \geq 1 - \delta - e^{-\frac{1}{2}t}.$$

Proof. Let $w(v_1), w(v_2), \cdots, w(v_n)$ be n i.i.d. random variables drawn uniformly from $[N]$. Let $(V, f_{G,w})$ be the *min-parent-forest* of (G, w). For a fixed $s \in V$, we create a set of random variables $z_1, z_2, \cdots, z_n$ by the following deterministic procedure:

1. Let $z_1 = w(s), k = 0, S_k = \{s\}, u_k = s, i = 2, \mathrm{pos}(s) \leftarrow 1$.
2. Let $S_{k+1} = S_k$.
3. For $j = 1 \to n$,

   if $v_j \in \Gamma(u_k)$ and $v_j \notin S_k$ then let $\mathrm{pos}(v_j) \leftarrow i, S_{k+1} \leftarrow S_{k+1} \cup \{v_j\}, z_i = w(v_j)$, $i \leftarrow i + 1$.
4. If $f_{G,w}(u_k) \neq u_k$, then let $u_{k+1} = f_{G,w}(u_k)$, $k \leftarrow k + 1$ and go to step 2.
5. Otherwise, for $j = 1 \to n$,

   if $v_j \notin S_{k+1}$ then let $\mathrm{pos}(v_j) \leftarrow i, z_i = w(v_j), i \leftarrow i + 1$.

It is easy to observe that k is exactly $\mathrm{dep}_{G,w}(s)$ at the end of the above procedure. The reason is that $u_0 = s = f^{(0)}_{G,w}(s)$, $\forall j \in [k], u_j = f_{G,w}(u_{j-1}) = f^{(j)}_{G,w}(s)$ and $f_{G,w}(u_k) = u_k$.

Fact 32.12.2. *$\forall v \in V$, $w(v) = z_{\mathrm{pos}(v)}$, where $\mathrm{pos} : [V] \to [n]$ and $\mathrm{pos}^{-1} : [n] \to [V]$.*

Claim 32.12.3. $\forall j \in \{0, 1, \cdots, k+1\}, S_j = \{u_0\} \cup \bigcup_{p=0}^{j-1} \Gamma(u_p)$.

Proof. We can prove this by induction. The statement is obviously true for S_0 since $S_0 = \{u_0\}$. Now suppose the claim is true for S_{j-1}. Then according to the step 3 of the procedure $S_j = S_{j-1} \cup (\Gamma(u_{j-1}) \setminus S_{j-1}) = S_{j-1} \cup \Gamma(u_{j-1}) = \{u_0\} \cup \bigcup_{p=0}^{j-1} \Gamma(u_p)$. □

Claim 32.12.4. $\forall j \in \{0, 1, \cdots, k\}$, $w(u_j) = \min_{v \in S_j} w(v)$.

Proof. Since $\forall j \in [k], u_j = f_{G,w}(u_{j-1})$, we have $w(u_j) = \min_{v \in \Gamma(u_{j-1}) \cup \{u_{j-1}\}} w(v)$. Then we have $w(u_j) = \min_{v \in \{u_0\} \cup \bigcup_{p=0}^{j-1} \Gamma(u_p)} w(v) = \min_{v \in S_j} w(v)$, where the last equality follows by Claim 32.12.3. □

We use $\text{pos}^{-1}(i)$ to denote vertex v which satisfies $\text{pos}(v) = i$. According to the step 3, it is easy to see $\forall j \in \{0, 1, \cdots, k+1\}$, we have $\{\text{pos}^{-1}(i) \mid i \in [|S_j|]\} = S_j$.

Claim 32.12.5. $\forall j \in \{0, 1, \cdots, k\}, z_{\text{pos}(u_j)} = \min_{p \in [\text{pos}(u_j)]} z_p$.

Proof. $z_{\text{pos}(u_j)} = w(u_j) = \min_{v \in S_j} w(v) = \min_{v \in S_j} z_{\text{pos}(v)} = \min_{p \in [|S_j|]} z_p = \min_{p \in [\text{pos}(u_j)]} z_p$, where the second equality follows by Claim 32.12.4, and the last equality follows by $u_j \in S_j$, so $\text{pos}(u_j) \leq |S_j|$. □

Now we define an another set of random variables $y_1, y_2, \cdots, y_n$, where $\forall i \in [n], y_i \in \{0, 1\}$ and $y_i = 1$ if and only if $z_i = \min_{j \in [i]} z_j$. According to Claim 32.12.5, we have that $\forall i \in \{0, 1, \cdots, k\}, y_{\text{pos}(u_i)} = 1$. Thus, $\text{dep}_{G,w}(s) = k \leq \sum_{i=1}^{n} y_i$. To upper bound $\text{dep}_{G,w}(s)$, it suffices to upper bound $\sum_{i=1}^{n} y_i$.

Before we look at $y_1, \cdots, y_n$, we firstly focus on the properties of $z_1, \cdots, z_n$:

Claim 32.12.6. *$z_1, z_2, \cdots, z_n$ are n i.i.d random variables drawn uniformly from $[N]$.*

Proof. A key observation is that if $z_1, z_2, \cdots, z_n$ are given, then we can recover $w(v_1), w(v_2), \cdots, w(v_n)$ exactly by the following deterministic procedure:

1. Let $w(s) = z_1, k = 0, S_k = \{s\}, u_k = s, i = 2$.
2. Let $S_{k+1} = S_k$.
3. For $j = 1 \to n$,

   if $v_j \in \Gamma(u_k)$ and $v_j \notin S_k$ then let $S_{k+1} \leftarrow S_{k+1} \cup \{v_j\}, w(v_j) = z_i$, $i \leftarrow i + 1$.
4. If $f_{G,w}(u_k) \neq u_k$, then let $u_{k+1} = f_{G,w}(u_k)$, $k \leftarrow k + 1$ and go to step 2.
5. Otherwise, for $j = 1 \to n$,

   if $v_j \notin S_{k+1}$ then let $\mathrm{pos}(v_j) \leftarrow i, w(v_j) = z_i, i \leftarrow i + 1$.

Notice that after step 3, $\forall v \in \Gamma(u_k) \cup \{u_k\}$, $w(v)$ is already recovered, thus we can implement step 4. Thus, the above procedure is a valid procedure. Since $z_1, \cdots, z_n$ are generated by $w(v_1), \cdots, w(v_n)$, we can also know $z_1, \cdots, z_n$ by given $w(v_1), \cdots, w(v_n)$. This means that

$$H(z_1, z_2, \cdots, z_n \mid w(v_1), w(v_2), \cdots, w(v_n)) = H(w(v_1), w(v_2), \cdots, w(v_n) \mid z_1, z_2, \cdots, z_n) = 0,$$

where $H(\cdot)$ is the information entropy. Notice that

$$\begin{aligned}
&I(z_1, z_2, \cdots, z_n; w(v_1), w(v_2), \cdots, w(v_n)) \\
&= H(z_1, z_2, \cdots, z_n) - H(z_1, z_2, \cdots, z_n \mid w(v_1), w(v_2), \cdots, w(v_n)) \\
&= H(w(v_1), w(v_2), \cdots, w(v_n)) - H(w(v_1), w(v_2), \cdots, w(v_n) \mid z_1, z_2, \cdots, z_n),
\end{aligned}$$

where $I(\cdot)$ is the mutual information. Thus, $H(z_1, z_2, \cdots, z_n) = H(w(v_1), w(v_2), \cdots, w(v_n)) = n \log N$. For $i \in [n]$, since the size of the support of z_i is at most N, $H(z_i) \leq \log N$ where the equality holds if and only if z_i is uniformly distributed on $[N]$. Also notice that $H(z_1, z_2, \cdots, z_n) \leq \sum_{i=1}^{n} H(z_i)$, where the equality holds if and only if z_i are independent. Since $\sum_{i=1}^{n} H(z_i) \leq n \log N$, we have $H(z_1, z_2, \cdots, z_n) = \sum_{i=1}^{n} H(z_i)$, and for each $i \in [n]$, $H(z_i) = \log N$. Thus, $z_1, z_2, \cdots, z_n$ are i.i.d. random variables drawn uniformly from $[N]$. □

Claim 32.12.7. *If $N > n^2/\delta$ for some $\delta \in (0, 1)$, then with probability at least $1 - \delta$, $\forall i \neq j \in [n]$, we have $w(v_i) \neq w(v_j)$.*

Proof. Recall that $w(v_1), w(v_2), \cdots, w(v_n)$ are n i.i.d. random variables drawn uniformly from N. For any $i \neq j \in [n]$, the $\Pr(w(v_i) \neq w(v_j)) = 1/N$, thus $\mathbb{E}(|\{(i, j) \in [n] \times [n] \mid i \neq j, w(v_i) \neq w(v_j)\}|) \leq n^2/N$. By Markov's inequality,

$$\Pr(|\{(i, j) \in [n] \times [n] \mid i \neq j, w(v_i) \neq w(v_j)\}| \geq 1) \leq n^2/N \leq \delta.$$

Thus,

$$\Pr(\forall i \neq j \in [n], z_i \neq z_j) \geq 1 - \delta.$$

□

Claim 32.12.8. *Let $\mathcal{E}$ be the event that $\forall i \neq j \in [n], w(v_i) \neq w(v_j)$. Then, for any $t \geq 3 \sum_{i=1}^{n} \frac{1}{i}$, we have*

$$\Pr_{w \sim [N]^n} \left(\sum_{i=1}^{n} y_i \geq t + \sum_{i=1}^{n} \frac{1}{i} \;\middle|\; \mathcal{E} \right) \leq e^{-\frac{3}{4}t}.$$

Proof. Note that $\mathcal{E}$ happened if and only if we have $\forall i \neq j \in [n], z_i \neq z_j$. Due to Claim 32.12.6, $z_1, z_2, \cdots, z_n$ are i.i.d. random variables drawn uniformly from $[N]$, then conditioned on $\mathcal{E}$, $y_1, y_2, \cdots, y_n$ are independent, and the probability that $y_i = 1$ is $1/i$. Thus, we have:

$$\begin{aligned}
& \Pr\left(\sum_{i=1}^{n} y_i \geq \sum_{i=1}^{n} \frac{1}{i} + t \;\middle|\; \mathcal{E}\right) \\
= \; & \Pr\left(\sum_{i=1}^{n} (y_i - \mathbb{E}\left(y_i \mid \mathcal{E}\right)) \geq t \;\middle|\; \mathcal{E}\right) \\
\leq \; & \exp\left(-\frac{\frac{1}{2}t^2}{\sum_{i=1}^{n} \mathbb{V}(y_i \mid \mathcal{E}) + \frac{1}{3}t}\right) \\
\leq \; & \exp\left(-\frac{\frac{1}{2}t^2}{\sum_{i=1}^{n} \frac{1}{i} + \frac{1}{3}t}\right) \\
\leq \; & \exp\left(-\frac{\frac{1}{2}t^2}{\frac{2}{3}t}\right) \\
= \; & \exp\left(-\frac{3}{4}t\right),
\end{aligned}$$

where the first equality follows by $\mathbb{E}(y_i|\mathcal{E}) = 1/i$. The first inequality follows by Berinstein inequality. The second inequality follows by

$$\sum_{i=1}^{n} \mathbb{V}(y_i \mid \mathcal{E}) \leq \sum_{i=1}^{n} \mathbb{E}(y_i^2 \mid \mathcal{E}) = \sum_{i=1}^{n} \mathbb{E}(y_i \mid \mathcal{E}) = \sum_{i=1}^{n} \frac{1}{i}.$$

The third inequality follows by $\sum_{i=1}^{n} \frac{1}{i} \leq \frac{1}{3}t$. □

For a fixed vertex $s \in V$, due to Claim 32.12.8, for any $t \geq 3\sum_{i=1}^{n} 1/i$, we have

$$\Pr\left(\mathrm{dep}_{G,w}(s) \geq \sum_{i=1}^{n} 1/i + t \;\middle|\; \mathcal{E}\right) \leq e^{-\frac{3}{4}t}. \tag{32.1}$$

Thus, for any $t \geq 60 \log n$,

$$
\begin{aligned}
& \Pr_{w \sim [N]^n} \left(\exists s \in V \text{ s.t. } \mathrm{dep}_{G,w}(s) \geq t \right) \\
\leq\ & \Pr \left(\exists s \in V \text{ s.t. } \mathrm{dep}_{G,w}(s) \geq 5t/6 + \sum_{i=1}^{n} 1/i \right) \\
=\ & \Pr \left(\exists s \in V \text{ s.t. } \mathrm{dep}_{G,w}(s) \geq 5t/6 + \sum_{i=1}^{n} 1/i \;\middle|\; \mathcal{E} \right) \Pr(\mathcal{E}) \\
& + \Pr \left(\exists s \in V \text{ s.t. } \mathrm{dep}_{G,w}(s) \geq 5t/6 + \sum_{i=1}^{n} 1/i \;\middle|\; \neg\mathcal{E} \right) \Pr(\neg\mathcal{E}) \\
\leq\ & \Pr \left(\exists s \in V \text{ s.t. } \mathrm{dep}_{G,w}(s) \geq 5t/6 + \sum_{i=1}^{n} 1/i \;\middle|\; \mathcal{E} \right) + \Pr(\neg\mathcal{E}) \\
\leq\ & \Pr \left(\exists s \in V \text{ s.t. } \mathrm{dep}_{G,w}(s) \geq 5t/6 + \sum_{i=1}^{n} 1/i \;\middle|\; \mathcal{E} \right) + \delta \\
\leq\ & \sum_{s \in V} \Pr \left(\mathrm{dep}_{G,w}(s) \geq 5t/6 + \sum_{i=1}^{n} 1/i \;\middle|\; \mathcal{E} \right) + \delta \\
\leq\ & n e^{-\frac{5}{8}t} + \delta \\
\leq\ & e^{-\frac{1}{2}t} + \delta
\end{aligned}
$$

where the first inequality follows by $\frac{1}{6}t \geq 10 \log n \geq \sum_{i=1}^{n} 1/i$. The third inequality follows by Claim 32.12.7. The forth inequality follows by union bound. The fifth inequality follows by Equation (32.1). The sixth inequality follows by $e^{-\frac{1}{8}t} \leq \frac{1}{n}$.

Thus, we can conclude that for any $t \geq 60 \log n$, we have $\Pr(\mathrm{dep}(G, w) \leq t) \geq 1 - \delta - e^{-\frac{1}{2}t}$. □

Lemma 32.12.9 (The number of roots of the random *min-parent-forest*)**.** *Let $G = (V, E)$ be an undirected graph with n vertices where $V = \{v_1, v_2, \cdots, v_n\}$, and the labels satisfies*

$v_1 < v_2 < \cdots < v_n$. *Let* $w(v_1), w(v_2), \cdots, w(v_n)$ *be* n *i.i.d. random variables drawn uniformly from* $[N]$. *Let* $\delta \in (0,1)$. *If* $N > n^3$, *then*

$$\Pr_{w \sim [N]^n} \left(|\{v \in V \mid f_{G,w}(v) = v\}| \geq \frac{2}{\delta} \sum_{v \in V} \frac{1}{|\Gamma(v)| + 1} \right) \leq \delta.$$

Proof. Let $w(v_1), w(v_2), \cdots, w(v_n)$ be n i.i.d. random variables drawn uniformly from $[N]$. Let $\mathcal{E}$ be the event that $\forall i \neq j \in [n], w(v_i) \neq w(v_j)$. Notice that for $i \neq j$, the probability that $w(v_i) = w(v_j)$ is $1/N$. Thus, $\mathbb{E}(|\{(i,j) \in [n] \times [n] \mid i \neq j, w(v_i) = w(v_j)\}|) \leq n^2/N$. Thus, if $N > n^2$, then $\Pr(\neg\mathcal{E}) = \Pr\left(|\{(i,j) \in [n] \times [n] \mid i \neq j, w(v_i) = w(v_j)\}| \geq 1\right) \leq n^2/N \leq \frac{1}{n}$. Now, we fix a vertex $v \in V$,

$$\begin{aligned}
& \Pr\left(f_{G,w}(v) = v\right) \\
= \; & \Pr\left(f_{G,w}(v) = v \mid \mathcal{E}\right) \Pr(\mathcal{E}) + \Pr\left(f_{G,w}(v) = v \mid \neg\mathcal{E}\right) \Pr(\neg\mathcal{E}) \\
\leq \; & \Pr\left(f_{G,w}(v) = v \mid \mathcal{E}\right) + \Pr(\neg\mathcal{E}) \\
\leq \; & \Pr\left(w(v) = \min_{u \in \{v\} \cup \Gamma(v)} w(u) \mid \mathcal{E}\right) + \frac{1}{n} \\
\leq \; & \frac{1}{|\Gamma(v)| + 1} + \frac{1}{n} \\
\leq \; & \frac{2}{|\Gamma(v)| + 1}
\end{aligned}$$

where the third inequality follows by the symmetry of all the variables $w(u)$ for $u \in \{v\} \cup \Gamma(v)$ so condition on all the w are different, with probability $\frac{1}{1+|\Gamma(v)|}$, $w(v)$ is the smallest one. The last inequality follows by $|\Gamma(v)| + 1 \leq |V| = n$.

Thus, $\mathbb{E}(|\{v \in V \mid f_{G,w}(v) = v\}|) \leq \sum_{v \in V} \frac{2}{|\Gamma(v)|+1}$. Let $\delta \in (0,1)$, then by Markov's inequality,

$$\Pr\left(|\{v \in V \mid f_{G,w}(v) = v\}| \geq \frac{2}{\delta} \sum_{v \in V} \frac{1}{|\Gamma(v)| + 1} \right) \leq \delta.$$

□

32.12.2 Leader Selection via Min Parent Forest

Given a graph, we can randomly assign each vertex a weight, thus we have a *min-parent-forest*, then we select those roots in the *min-parent-forest* as leaders, and try to contract all the vertices to the leaders. If we replace line 13 to line 17 of Algorithm 32.3 by Algorithm 32.20. We can get a new algorithm with the following guarantees.

Theorem 32.12.10. *Suppose we replace line 13 to line 17 of Algorithm 32.3 by Algorithm 32.20.*

Let $G = (V, E)$ be an undirected graph, $m = \Omega(n)$, and $r \leq n$ be the rounds parameter where n is the number of vertices in G. Let $c > 0$ be a sufficiently large constant. If $r \geq c \log \log_{m/n}(n)$, then with probability at least $2/3$, the modified CONNECTIVITY(G, m, r) *(Algorithm 32.3) will not return FAIL, and the total number of iterations (see Definition 32.4.6) of the modified* CONNECTIVITY(G, m, r) *is at most $O(r \cdot (\log D + \log \log n))$, where $D = \operatorname{diam}(G)$.*

Proof. Let k_i denote the number of iterations (see Definition 32.4.1) of NEIGHBORINCREMENT(m, G_{i-1}). By Lemma 32.4.2, we have $k_i \leq O(\log D)$. Thus, $\sum_{i=1}^{r} k_i = O(r \cdot \log D)$.

According to Lemma 32.12.1, with probability at least $1 - \frac{2}{100r}$, $\operatorname{dep}(G_i'', w_i) \leq O(\log n)$. By Lemma 32.4.6, with probability at least $1 - \frac{2}{100r}$, the number of iteration of TREECONTRACTION$(G_i'', \mathrm{par}_i$ (see Definition 32.4.5) $r_i' \leq O(\log \log n)$ By taking union bound over all $i \in [r]$, then with probability at least $1 - \frac{1}{50}$, $\sum_{i=1}^{r} r_i' \leq O(r \cdot \log \log n)$.

Due to the Property 3 of Lemma 32.4.2, $\forall i \in [r]$, $\forall v \in V_i'', u \in \Gamma_{G_i'}(v)$, we have $u \in V_i''$ which means that $u \in \Gamma_{G_i''}(v)$. Thus, $|\Gamma_{G_i''}(v)| \geq \lceil (m/n_{i-1})^{1/2} \rceil - 1$. Then due

to Lemma 32.12.9, we have that with probability at most $\frac{1}{8}$, $n_i \geq 16n_{i-1}^{3/2}/m^{1/2}$. Since $m/n \geq m/n_i \geq 1024$, we have that with probability at most $\frac{1}{8}$, $n_i \geq n_{i-1}^{11/10}/m^{1/10}$. Let $y_1, y_2, \cdots, y_r$ be r random variables. If $n_i \geq n_{i-1}^{11/10}/m^{1/10}$, then $y_i = 1$, otherwise $y_i = 0$. We have $\mathbb{E}(\sum_{i=1}^{r} y_i) \leq \frac{r}{8}$. By Markov's inequality, we have $\Pr(\sum_{i=1}^{r} y_i \geq \frac{r}{2}) \leq \frac{1}{4}$. Thus, with probability at least $\frac{3}{4}$, $\sum_{i=1}^{r} y_i \leq \frac{r}{2}$. Notice that when $y_i = 0$, then $n_i \leq n_{i-1}^{11/10}/m^{1/10}$, and when $y_i = 1$, we have $n_i \leq n_{i-1}$. So if there are at least $\frac{r}{2}$ number of y_is which are 0, then

$$
\begin{aligned}
n_r &\leq \frac{\left(\frac{\left(\frac{n^{1.1}}{m^{0.1}}\right)^{1.1}}{m^{0.1}}\right)^{\cdots}}{\cdots} && \text{(Apply } r/2 \text{ times)} \\
&= \frac{n^{1.1^{r/2}}}{m^{1.1^{r/2-1}}} \\
&= n/(m/n)^{1.1^{r/2-1}} \\
&\leq n/(m/n)^{1.1^{r/4}} \\
&\leq \frac{1}{2}
\end{aligned}
$$

where the last inequality follows by $r \geq \frac{4}{\log 1.1}(\log\log_{m/n}(2n))$. Since n_r is an integer, when $n_r \leq \frac{1}{2}$, $n_r = 0$. Thus, we can conclude that if $r \geq c \cdot \log\log_{m/n} n$ for a sufficiently large constant $c > 0$, then with probability at least $\frac{3}{4} - \frac{1}{50} \geq \frac{2}{3}$, the modified CONNECTIVITY(G, m, r) will not output FAIL. □

Notice that though the theoretical guarantees of the *min-parent-forest* leader selection method is worse than the random leader sampling, the merit of *min-parent-forest* leader selection method is that it can have an "early start".

Consider the case when the total space size m is $\Theta(n)$. In this case, random leader sampling will always sample a half of the vertices as the leaders until the total space m is

poly($\log n$) larger than the number of vertices. However, *min-parent-forest* leader selection method can make a large progress at the beginning, it will choose the number of leaders to be about the sum of inverse degrees. Furthermore, the depth of the *min-parent-forest* may not always have $\log n$ depth. Thus, it is an interesting question which leader selection approach has better performance in practice.

Algorithm 32.3 Graph Connectivity

procedure CONNECTIVITY($G = (V, E), m, r$) ▷ Theorem 32.4.9, Theorem 32.4.15
  Output: FAIL or col : $V \to V$.
  $n \leftarrow |V|$
  $\forall v \in V$, $h_0(v) \leftarrow$ null.
  $G_0 = (V_0, E_0) = G$, i.e. $V_0 = V, E_0 = E$.
  $n_0 = n$.
  for $i = 1 \to r$ **do**
    $\forall v \in V$, $h_i(v) \leftarrow$ null. ▷ $h_i(v)$ is the vertex that v contracts to
    $G'_i = (V'_i, E'_i) =$ NEIGHBORINCREMENT(m, G_{i-1}). ▷ Algorithm 32.1
    Compute $V''_i = \{v \in V'_i \mid |\Gamma_{G'_i}(v)| \geq \lceil (m/n_{i-1})^{1/2} \rceil - 1\}$.
    Compute $E''_i = \{(u, v) \in E_{i-1} \mid u \in V''_i, v \in V''_i\}$.
    $G''_i = (V''_i, E''_i)$. ▷ G''_i is obtained by removing all the small components of G_i
    Let $\gamma_i = \lceil (m/n_{i-1})^{1/2} \rceil, p_i = \min((30 \log(n) + 100)/\gamma_i, 1/2)$.
    Let $l_i : V''_i \to \{0, 1\}$ be a random hash function such that $\forall v \in V''_i, l_i(v)$ are i.i.d. Bernoulli random variables, and $\Pr(l_i(v) = 1) = p_i$.
    Let $L_i = \{v \in V''_i \mid l_i(v) = 1\} \cup \{v \in V''_i \mid \forall u \in \Gamma_{G'_i}(v) \cup \{v\}, l_i(u) = 0\}$. ▷ L_i are leaders
    $\forall v \in V''_i$ with $v \in L_i$, let $\mathrm{par}_i(v) = v$.
    $\forall v \in V''_i$ with $v \notin L_i$, let $\mathrm{par}_i(v) = \min_{u \in L_i \cap (\Gamma_{G'_i}(v) \cup \{v\})} u$. ▷ Non-leader finds a leader.
    Let $((V_i, E_i), g_i^{(r'_i)}) =$ TREECONTRACTION(G''_i, par_i). ▷ Algorithm 32.2
    $G_i = (V_i, E_i)$.
    $n_i = |V_i|$.
    For each $v \in V'_i \setminus V''_i$, let $h_i(v) \leftarrow \min_{u \in \Gamma_{G'_i}(v) \cup \{v\}} u$. ▷ Contract small component to one vertex
    For each $v \in V''_i \setminus V_i$, let $h_i(v) \leftarrow g_i^{(r'_i)}(v)$. ▷ Contract non-leader to leader
    For each $v \in V$, if $h_{i-1}(v) \neq$ null, then let $h_i(v) = h_{i-1}(v)$.
  end for
  If $n_r \neq 0$, return FAIL.

  end for
  return $\widehat{\mathrm{par}}$.
end procedure

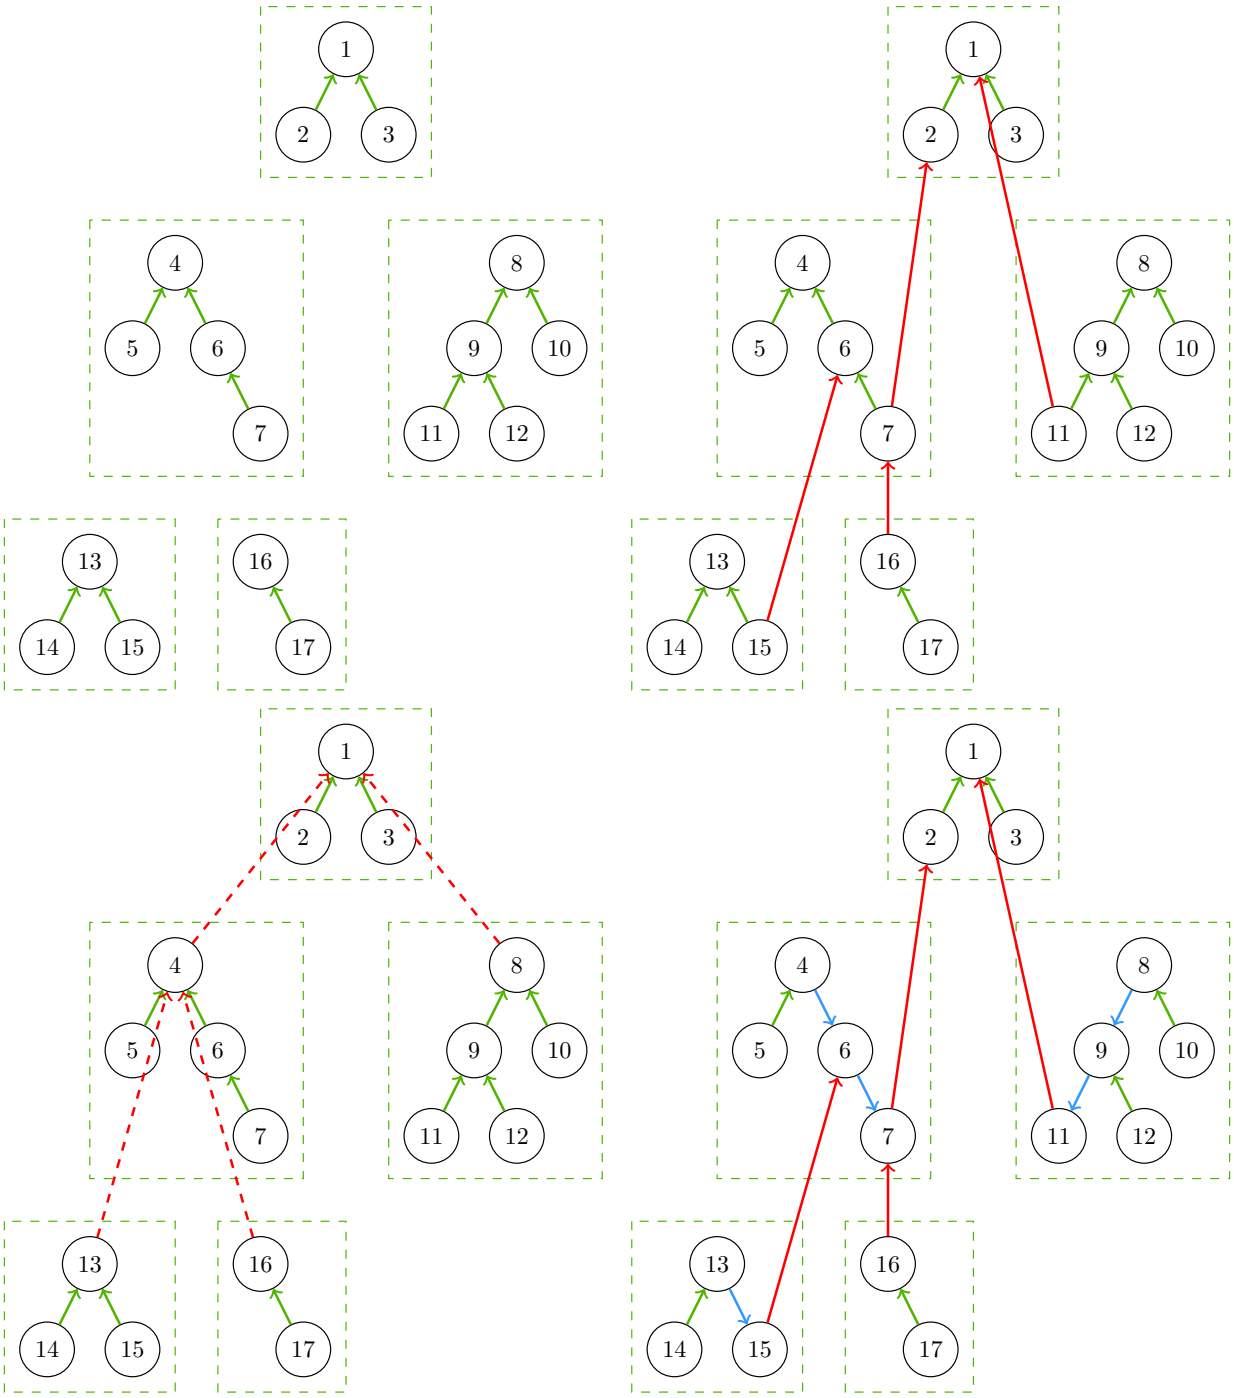

Figure 32.1: Each tree with green edges on the top-left is a rooted tree of each contracted component. For example, there are five components $\{1, 2, 3\}, \{4, 5, 6, 7\}$, $\{8, 9, 10, 11, 12\}, \{13, 14, 15\}, \{16, 17\}$. The dashed edges in the bottom-left figure is a root spanning tree of five components. The red edges in the top-right figure correspond to the dashed edges in the bottom-left figure before contraction. In bottom-right figure, by changing (see blue edges) the root of each contracted tree, we get a rooted spanning tree in the original graph

Probability and Inequality Tools

A.1 Scalar version probability tools

Lemma A.1.1 (Chernoff bounds [Che52]). *Let $x_1, \cdots, x_n$ be independent random variables. Assume that $x_i \in [0,1]$ always, for each $i \in [n]$. Let $x = \sum_{i=1}^n$ and $\mu = \mathbb{E}[x] = \sum_{i=1}^n \mathbb{E}[x_i]$. Then for any $\epsilon > 0$*

$$\Pr[x \geq (1+\epsilon)\mu] \leq \exp\left(-\frac{\epsilon^2}{2+\epsilon}\mu\right), \quad \text{and} \quad \Pr[x \leq (1-\epsilon)\mu] \leq \exp\left(-\frac{\epsilon^2}{2}\mu\right).$$

Lemma A.1.2 (Bernstein inequality [Ber24]). *Let $x_1, \cdots, x_n$ be independent zero-mean variables. Suppose $|x_i| \leq M$ almost surely, for all $i \in [n]$. Then for all positive t,*

$$\Pr\left[\sum_{i=1}^n x_i > t\right] \leq \exp\left(-\frac{t^2/2}{\sum_{i=1}^n \mathbb{E}[x_i^2] + Mt/3}\right).$$

Lemma A.1.3 (Hanson-Wright inequality [HW71, Wri73]). *Let $x = (x_1, \cdots, x_n) \in \mathbb{R}^n$ be a random vector with independent components x_i which satisfy $\mathbb{E}[x_i] = 0$ and $\|x_i\|_{\psi_2} \leq K$ (where $\|x_i\|_{\psi_2} := \sup_{p \geq 1} p^{-1/2}(\mathbb{E}[|x_i|^p])^{1/p}$). Let A be an $n \times n$ matrix. Then, for every $t \geq 0$,*

$$\Pr\left[\left|x^\top A x - \mathbb{E}[x^\top A x]\right| > t\right] \leq 2\exp\left(-c \cdot \min\left(\frac{t^2}{K^4\|A\|_F^2}, \frac{t}{K^2\|A\|}\right)\right).$$

Lemma A.1.4 (Khintchine's inequality [Haa81]). *Let $\sigma_1, \cdots, \sigma_n$ be i.i.d. sign random variables, and let $z_1, \cdots, z_n$ be real numbers. Then there are constants $C, C' > 0$ so that*

$$\Pr\left[\left|\sum_{i=1}^n z_i \sigma_i\right| \geq Ct\|z\|_2\right] \leq \exp(-C't^2).$$

Lemma A.1.5 (Hoeffding inequality [Hoe63])**.** *Let $x_i \in [a_i, b_i]$ denote independent random variables, let $x = \frac{1}{n}\sum_{i=1}^{n} x_i$ then*

$$\Pr[|x - \mathbb{E}[x]| \geq t] \leq 2\exp\left(-\frac{2n^2t^2}{\sum_{i=1}^{n}(b_i - a_i)^2}\right).$$

Lemma A.1.6 (Lemma 1 on page 1325 of [LM00])**.** *Let $x \sim \mathcal{X}_k^2$ be a chi-squared distributed random variable with k degrees of freedom. Each one has zero mean and σ^2 variance. Then*

$$\Pr[x - k\sigma^2 \geq (2\sqrt{kt} + 2t)\sigma^2] \leq \exp(-t)$$
$$\Pr[k\sigma^2 - x \geq 2\sqrt{kt}\sigma^2] \leq \exp(-t)$$

A.1.1 Reverse Chernoff bound

In this Section, we prove that the classical Chernoff bound is tight in some regimes. There are several different proofs, e.g. [Mou10, Slu77, AB09, YZD12]. For completeness, we provide a proof from [YZD12].

Fact A.1.7. *If $1 \leq l \leq k-1$, then*

$$\binom{k}{l} \geq \frac{1}{e\sqrt{2\pi l}}(\frac{k}{l})^l(\frac{k}{k-l})^{k-l}.$$

Proof. By Stirling's approximation, $i! = \sqrt{2\pi i}(i/e)^i e^\lambda$ for some $\lambda \in [1/(12i+1), 1/(12i)]$.

Thus,

$$\begin{aligned}\binom{k}{l} &= \frac{k!}{l!(k-l)!} \\ &\geq \frac{\sqrt{2\pi k}(\frac{k}{e})^k}{\sqrt{2\pi l}(\frac{l}{e})^l \sqrt{2\pi(k-l)}(\frac{k-l}{e})^{k-l}} \exp(\frac{1}{12k+1} - \frac{1}{12l} - \frac{1}{12(k-l)}) \\ &\geq \frac{\sqrt{2\pi k}(\frac{k}{e})^k}{\sqrt{2\pi l}(\frac{l}{e})^l \sqrt{2\pi(k-l)}(\frac{k-l}{e})^{k-l}} e^{-1} \\ &\geq \frac{1}{\sqrt{2\pi l}}(\frac{k}{l})^l (\frac{k}{k-l})^{k-l} e^{-1}.\end{aligned}$$

where the first step follows by definition, the second step follows by Stirling's approximation, the third step follows by $\frac{1}{1+a+b} + 1 \geq \frac{1}{a} + \frac{1}{b}$ for $a \geq 12, b \geq 12$.

□

Now, we are ready to prove the following result

Lemma A.1.8 ([Mou10, Slu77, AB09, YZD12]). *Let X be the average of k independent, Bernoulli random variables with mean p. For any $\epsilon \in (0, 1/2]$ and $p \in (0, 1/2]$, assuming $\epsilon^2 pk \geq 3$, we have*

$$\Pr[X \leq (1-\epsilon)p] \geq \exp(-9\epsilon^2 pk),$$

and

$$\Pr[X \geq (1+\epsilon)p] \geq \exp(-9\epsilon^2 pk).$$

Proof. Note that $\Pr[X \leq (1-\epsilon)p]$ equals the sum $\sum_{i=0}^{\lfloor (1-\epsilon)pk \rfloor} \Pr[X = i/k]$, and $\Pr[X = i/k] = \binom{k}{i} p^i (1-p)^{k-i}$.

Fix $l = \lfloor (1-2\epsilon)pk \rfloor + 1$. The terms in the sum are increasing, so the terms with index $i \geq \ell$ each have value at least $\Pr[X = l/k]$, so their sum has total value at least $(\epsilon pk - 2)\Pr[X = l/k]$. To complete the proof, we show that

$$(\epsilon pk - 2)\Pr[X = l/k] \geq \exp(-9\epsilon^2 pk).$$

The assumptions $\epsilon^2 pk \geq 3$ and $\epsilon \leq 1/2$ give $\epsilon pk \geq 6$, so we have

$$\begin{aligned}(\epsilon pk - 2)\Pr[X = l/k] &\geq \frac{2}{3}\epsilon pk \binom{k}{l} p^l (1-p)^{k-l} \\ &\geq \underbrace{\frac{2}{3}\epsilon pk \frac{1}{\sqrt{2\pi l}}}_{A} \cdot \underbrace{(\frac{k}{l})^l (\frac{k}{k-l})^{k-l} p^l (1-p)^{k-l}}_{B}\end{aligned}$$

Below, we will show that $A \geq \exp(-\epsilon^2 pk)$ and $B \geq \exp(-8\epsilon^2 pk)$.

Claim A.1.9. $A \geq \exp(-\epsilon^2 pk)$.

Proof. The assumptions $\epsilon^2 pk \geq 3$ and $\epsilon \leq 1/2$ imply that $pk \geq 12$.

By $l \leq pk + 1$ (from definition), and $pk \geq 12$, thus $l \leq 1.1pk$.

Therefore, we have

$$\begin{aligned}A &\geq \frac{2}{3e}\epsilon\sqrt{pk/(2.2\pi)} \\ &\geq \frac{2}{3e}\sqrt{3/(2.2\pi)} && \text{by } \epsilon\sqrt{pk} \geq \sqrt{3} \\ &\geq 0.1 \\ &\geq \exp(-3) \\ &\geq \exp(-\epsilon^2 pk).\end{aligned}$$

This completes the proof of the claim. □

Claim A.1.10. $B \geq \exp(-8\epsilon^2 pk)$.

Proof. Fix δ such that $l = (1-\delta)pk$. The choice of l implies $\delta \leq 2\epsilon$, so the claim will hold as long as $B \geq \exp(-2\delta^2 pk)$. Manipulting this latter inequality, we get

$$\begin{aligned} & B^{-1/l} \leq \exp(\frac{2\delta^2 pk}{l}) \\ \iff & \frac{l}{pk}(\frac{k-l}{(1-p)k})^{k/l-1} \leq \exp(\frac{2\delta^2 pk}{l}). \end{aligned}$$

Substituting $l = (1-\delta)pk$ and simplifying, it is equivalent to

$$(1-\delta)(1+\frac{\delta p}{1-p})^{\frac{1}{(1-\delta)p}-1} \leq \exp(\frac{2\delta^2}{1-\delta}).$$

Taking the logarithm of both sides, we have

$$\ln(1-\delta) + (\frac{1}{(1-\delta)p} - 1)(\ln(1+\frac{\delta p}{1-p})) \leq \frac{2\delta^2}{1-\delta}$$

Since $\ln(1+z) \leq z$, it suffices to prove

$$\begin{aligned} & -\delta + (\frac{1}{(1-\delta)p} - 1)(\frac{\delta p}{1-p}) \leq \frac{2\delta^2}{1-\delta} \\ \iff & \frac{\delta^2}{(1-p)(1-\delta)} \leq \frac{2\delta^2}{1-\delta}. \end{aligned}$$

Since $p \leq 1/2$, this finishes the proof of the claim. □

Combining the above two claims, we obtain the desired probability lower bound for the $(1-\epsilon)$ side. We can prove it for the $(1+\epsilon)$ side similarly. □

Lemma A.1.11 (Anti-concentration of Gaussian distribution)**.** *Let $X \sim N(0, \sigma^2)$, that is, the probability density function of X is given by $\phi(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{x^2}{2\sigma^2}}$. Then*

$$\Pr[|X| \leq t] \in \left(\frac{2}{3}\frac{t}{\sigma}, \frac{4}{5}\frac{t}{\sigma}\right).$$

A.2 Matrix version probability tools

We state a version from [Tro11c], and there is also another version can be found in [OT09].

Lemma A.2.1 (Matrix Freedman). *Consider a matrix martingale* $\{Y_i : i = 0, 1, 2, \cdots\}$ *whose values are self-adjoint matrices with dimension* n*, and let* $\{X_i : i = 1, 2, 3, \cdots\}$ *be the difference sequence. Assume that the difference sequence is uniformly bounded in the sense that*

$$\lambda_{\max}(X_i) \leq R, \text{ almost surely } \text{ for } i = 1, 2, 3, \cdots.$$

Define the predictable quadratic variation process of the martingale :

$$W_i = \sum_{j=1}^{i} \mathbb{E}_{j-1}[X_j^2], \text{ for } i = 1, 2, 3, \cdots.$$

Then, for all $t \geq 0$ *and* $\sigma^2 > 0$*,*

$$\Pr\left[\exists i \geq 0 : \lambda_{\max}(Y_i) \geq t \text{ and } \|W_i\| \leq \sigma^2\right] \leq n \cdot \exp\left(-\frac{t^2/2}{\sigma^2 + Rt/3}\right).$$

Lemma A.2.2 (Matrix Bernstein, Theorem 6.1.1 in [Tro15]). *Consider a finite sequence* $\{X_1, \cdots, X_m\} \subset \mathbb{R}^{n_1 \times n_2}$ *of independent, random matrices with common dimension* $n_1 \times n_2$*. Assume that*

$$\mathbb{E}[X_i] = 0, \forall i \in [m] \quad \text{and} \quad \|X_i\| \leq M, \forall i \in [m].$$

Let $Z = \sum_{i=1}^{m} X_i$*. Let* $\mathrm{Var}[Z]$ *be the matrix variance statistic of sum:*

$$\mathrm{Var}[Z] = \max\left\{\left\|\sum_{i=1}^{m} \mathbb{E}[X_i X_i^\top]\right\|, \left\|\sum_{i=1}^{m} \mathbb{E}[X_i^\top X_i]\right\|\right\}.$$

Then

$$\mathbb{E}[\|Z\|] \leq (2\mathrm{Var}[Z] \cdot \log(n_1 + n_2))^{1/2} + M \cdot \log(n_1 + n_2)/3.$$

Furthermore, for all $t \geq 0$*,*

$$\Pr[\|Z\| \geq t] \leq (n_1 + n_2) \cdot \exp\left(-\frac{t^2/2}{\mathrm{Var}[Z] + Mt/3}\right).$$

A.3 Inequalities

We state the Hölder's inequality for complex numbers. We will use the corresponding version $p = q = 2$ of Cauchy-Schwarz inequality for complex numbers.

Lemma A.3.1 (Hölder's inequality)**.** *If* S *is a measurable subset of* $\mathbb{R}^n$ *with the Lebesgue measure, and* f *and* g *are measurable complex-valued functions on* S*, then*

$$\int_S |f(x)g(x)|\mathrm{d}x \leq \left(\int_S |f(x)|^p \mathrm{d}x\right)^{\frac{1}{p}} \left(\int_S |g(x)|^q \mathrm{d}x\right)^{\frac{1}{q}}$$

Fact A.3.2. *For any vector* $x \in \mathbb{R}^n$*, we have*

$$\|x\|_2 \leq \|x\|_1 \leq \sqrt{n}\|x\|_2.$$

For any matrix $A \in \mathbb{R}^{n \times d}$*, we have*

$$\|A\|_F \leq \|A\|_1 \leq \sqrt{nd}\|A\|_F,$$

and

$$\|A\| \leq \|A\|_F \leq \sqrt{d} \cdot \|A\|.$$
